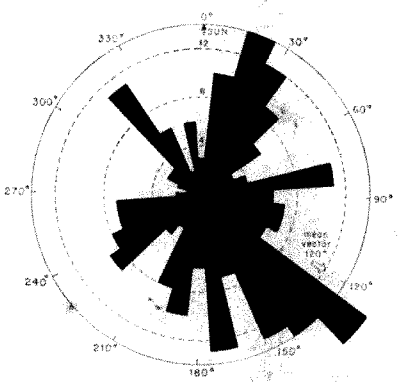
ATP...A-OK...PDQ...from TRC!

Short of actual despatch by guided missile,
The Radiochemical Centre, Amersham, does everything humanly possible to ensure that your supplies of ATP-P32 reach you regularly, on time, at the highest specific activity, and accurately labelled.

The labelling position of all ATP-P32 compounds issued from Amersham has been verified by sequential degradation and > 98% of activity is in the stated position. The compounds are prepared to the following specific activities:

Adenosine-5'-triphosphate-α-P32 (sodium salt)
up to 1,500 mCi/mmol. Prepared monthly and usually available from stock. Supplied in 50% aqueous ethanol to reduce radiation decomposition.



Adenosine-5'-triphosphate-γ-P32 (sodium salt)
up to 2,500 mCi/mmol. Prepared monthly and usually available from stock. Supplied in 50% aqueous ethanol to reduce radiation decomposition.

Adenosine-5'-triphosphate-γ-P32 (ammonium salt)
about 20,000 mCi/mmol at time of preparation. Prepared monthly and usually despatched immediately. Supplied as the freeze-dried salt.

All three products are very competitively priced and in convenient package sizes.

SECOND-CLASS POSTAGE PAID AT NEW YORK, N.

CUK-H06832-232-RP362

Order our new manual and get in on the latest enzyme action

RP362

Act Now. Mail the coupon below for your free copy of our exclusive new Enzyme Manual.

What's in it for you? The world's most complete selection of crystalline and purified enzymes prepared specifically for research.

Our manual contains technical data and specifications along with carefully documented literature references.

Our Enzyme Manual is a nice introduction to our company, the number one supplier of quality research biochemicals. So, let's get acquainted. A postage stamp is all you need to start the action.

Nutritional Biochemicals Corporation

Only four controls —but what performance!

Simple to look at . . . just as simple to use. The new Unicam SP1000 Infrared Spectrophotometer.

Give your new lab technician a few minutes' instruction, and you have an immediate capacity for infrared spectra of the highest quality. You might think, because of all that simplicity, that we have sacrificed something along the way. Just one thing—the price. Everything else is comparable to instruments costing very much more.

How is this possible? For one thing we have introduced a high performance Ebert grating monochromator which gives excellent resolution. Then there is an improved pneumatic detector incorporating solid-state circuitry, and a large (20 cm x 48 cm) integral strip chart recorder for supremely clear results. A full range spectrum (625-3800 cm⁻¹) will take you just two minutes, or for work of the highest precision press the "slow scan" button and wait less than five and a half minutes.

It will certainly pay you to learn more about the SP1000. Or if your needs are even more demanding then there is the Unicam SP120. Write or 'phone today for a free brochure.

TELLURIUM and TELLURIDES

D. M. Chizhikov & V. P. Shchastlivyi

(*Translated from the Russian by Dr. Eugene M. Elkin*)

320 pp. 23 cm × 16 cm. Cloth. 103 figures, charts and tables; extensive bibliography; subject index.

Ref. 5560 170*s.* (£8.50)

The first comprehensive monograph on the subject, including 18 chapters on properties, uses, production and consumption of tellurium; raw materials; behaviour and distribution; production of crude and high-purity tellurium; properties, preparation and refining of 8 groups of tellurides.

Also available by the same authors:

SELENIUM and SELENIDES

403 pp. 23 cm × 16 cm. Cloth. Ref. 3528. 152s. 6d. (£7.60)

A reviewer in "Nature" (Sept. 1968) concludes:

"The value of this reference work has justified its translation and, because of the collection of data from both Western and Soviet sources, the usefulness of the English edition will not be impaired."

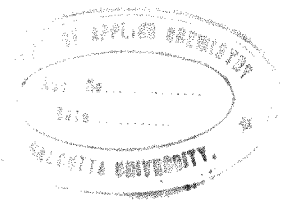
Pye Unicam has a new automatic enzyme analyser. This is what makes it tick.



It is the new Unicam AC61 Programme Delay Unit, which holds the reacting mixture in a spectrophotometer flow cell from 5 seconds to 5 minutes while the change in absorbance is measured.
The whole system – comprised of an automatic chemical processing unit, a spectrophotometer and a recorder – has been designed for versatility and precision at low cost.
The system is simple to operate. Programming takes only a few minutes. Sample and reagent volumes are controlled by preformed templates. No initial sample preparation is required.
Enzyme reaction rates can be measured and recorded completely automatically at speeds ranging from 12 – 60 an hour, while other chemical analyses can be completed at up to 120 samples an hour.
Above all, the system is backed by methods proved in the Pye Unicam Applications Laboratory and over 20 method sheets are currently available including LDH, CPK, SGOT and SGPT in serum.
Find out more about the Unicam Automatic Analytical System by telephoning or writing to Pye Unicam today.

Food Science and Technology: A series of monographs

The Biochemistry of Fruit and their Products

In two volumes

Edited by A. C. Hulme *A.R.C. Food Research Institute, Norwich, England*

Volume 1 October 1970, xii+620 pp., 200s. (£10.00)

This volume deals mainly with the chemistry of the groups of compounds found in plants, with special reference to their specific roles in fruit metabolism. It also examines the phenomena of hormonal control of growth and maturation as well as the metabolism of the harvested fruit.

Contents 1. Constituents of fruits. Sugars. Hexosans, pentosans and gums. Pectic substances and other uronides. Organic acids. Amino acids. Proteins. Protein patterns in fruits. Enzymes. Fruit lipids. Volatile compounds: the aroma of fruits. Fruit phenolics. Carotenoids and triterpenoids. Vitamins in fruits. **2. Growth and pre-harvest factors.** The physiology and nutrition of developing fruits. Hormonal factors in growth and development. **3A. Biochemistry of maturation and ripening.** The ethylene factor. The climacteric and ripening of fruits. **3B. Physiological disorders of fruits.** Physiological disorders of fruits after harvesting. Apple scald.
Author index. Subject index.

Physiology of Tree Crops

Proceedings of a symposium held at Long Ashton Research Station, University of Bristol 1969

Edited by L. C. Luckwill and C. V. Cutting *Long Ashton Research Station, University of Bristol, England*

October 1970, xiv+382 pp. 120s. (£6.00)

Apical dominance, ageing and dormancy, the mechanisms controlling the balance of vegetative and reproductive development, the transport and storage of water and metabolites, the relations between the tree and its aerial and subterranean environments and, most important, the complex hormonal interactions which co-ordinate growth in the whole tree are some of the themes of this book. For the first time progress in physiological investigations of fruit trees, forestry and plantation crops have been co-ordinated. It will interest not only botanists and plant physiologists, but also forestry researchers, pomologists, viticulturists and specialists in tropical tree crops.

Aerobiology

Proceedings of the Third International Symposium

General Editor: I. H. Silver *Microbiological Research Establishment, Porton Down, Wiltshire England*

October 1970, xvi+278 pp. 70s. (£3.50)

This volume concentrates on the problems facing scientists and medical workers who are studying the spread and control of airborne disease. It extends the previous coverage to include preventive medicine and specific problems encountered in hospitals. For scientific and medical research workers, and post-graduate students in hospitals, universities and research institutes.

Contents Airborne infections in closed and segregated environments. Intramural spread of infection, airborne or not? Laboratory safety. Immunological aspects of pathogenesis. Value and use of germ-free environments. Vaccines and methods of vaccination. Microbial survival in air. Rapid diagnosis. Physiological and genetic factors in host resistance. Techniques in aerobiology. How do airborne particles initiate infection?

Essays in Physics

Edited by G. K. T. and G. N. Fowler *Department of Physics, University of Exeter, England*

Volume 2 October 1970, x+168 pp. 30s. (£1.50)

This is the second volume of a series intended for all physicists from third-year students and post-graduate researchers upwards. Pipkin's article, which resolves the discrepancy between theory and experiment on the Lamb shift in hydrogen, is of central importance, while those of Landsberg and Wolfendale are likely to become so.

Contents Quantum electrodynamics. Concepts in special relativistic thermodynamics. Neutrino-physics.

Advances in Insect Physiology

Edited by J. W. L. Beament, J. E. Treherne and V. B. Wigglesworth *Department of Zoology, Cambridge University, Cambridge, England*

Volume 7 October 1970, x+470 pp. 140s. (£7.00)

The aim of this series is to relate the physiology of insects to other areas of biological science. The review serves as a guide to recently acquired knowledge and also as a catalyst for further advances in the subject.

Contents Function and structure of polytene chromosomes during insect development. The structure and function of the insect dorsal ocellus. Polarity and patterns in the postembryonic development of insects. Regulation of intermediary metabolism, with special reference to the control mechanisms in insect flight muscle. Cellular mechanisms underlying behaviour—neuroethology.
Author index. Subject index. Cumulative list of authors. Cumulative list of chapter titles.

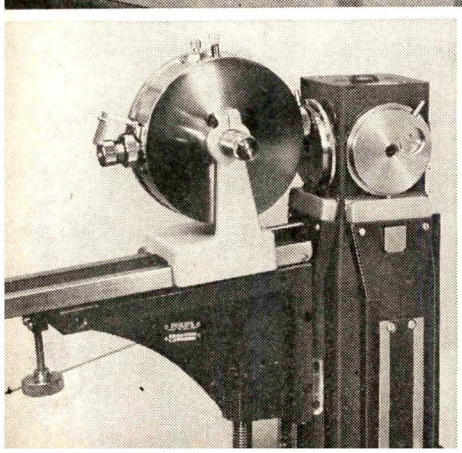
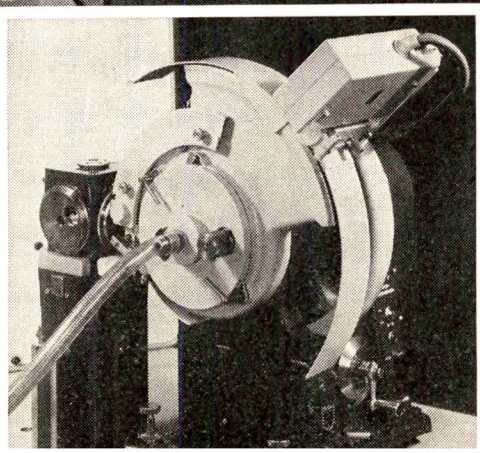
What do you want in X-ray diffractometry?

PHILIPS



People with problems in X-ray diffractometry are very important to the design of Philips X-ray diffraction equipment. After all, if we do not know the problems you are facing, how can we produce the right instruments? But this information alone is not enough. It needs the backing of Philips' own technological experience and vast research effort. The result is a range of equipment that is the most advanced of its type.



Look at what is available for industry and research. Three models of 3kW generators, vertical and horizontal goniometers with diffraction sets, Debye-Scherrer and universal flat plate cameras with all the accessories, high-temperature attachment, automatic sample changer, texture attachment, metallurgical kit, Eulerian cradle, vacuum attachment, auto-focus specimen holder, detectors, tubes, circuit panels – exactly what you want in X-ray diffractometry. And when you suggested a computer-controlled instrument we had the answer in the PW1100 single-crystal diffractometer – complete with all the software you normally have to provide yourself. The fact is, by helping us we are helping you to keep way out in front in X-ray diffractometry. Get the full story from Pye Unicam Ltd – write for free brochures today.

Lead tin telluride forms the basis of a new semiconductor device sensitive to infra-red radiation of wavelength 8–14 μm, developed by Plessey. With a detectivity $D^* = 2 \times 10^{10}$ cm hertz$^{\frac{1}{2}}$ watt^{-1} and a response speed of 10 nanosecs, the device, which operates at −77°C, opens a new field of technology in thermal imaging and communications, where it can be used to produce more noise free systems through heterodyning laser beams.

Research into the production of a uniformly thin layer of uniform composition was carried out using the Cambridge Stereoscan. This picture is in fact of one of the crystalline whiskers produced as a by-product of the crystallisation process. The vital features of the Stereoscan which saved so much valuable time were the large depth of focus, the simplicity of operation and the fact that so little specimen preparative procedure was needed. For analysing composition through the layer, the Cambridge Microscan 5 provided an essential facility and enabled analysis studies to be made at the same time as further examinations were made on the Stereoscan.

ATP...A-OK...PDQ...from TRC!

Short of actual despatch by guided missile,
The Radiochemical Centre, Amersham, does everything humanly possible to ensure that your supplies of ATP-P32 reach you regularly, on time, at the highest specific activity, and accurately labelled.

The labelling position of all ATP-P32 compounds issued from Amersham has been verified by sequential degradation and > 98% of activity is in the stated position. The compounds are prepared to the following specific activities:

Adenosine-5'-triphosphate-α-P32 (sodium salt)
up to 1,500 mCi/mmol. Prepared monthly and usually available from stock. Supplied in 50% aqueous ethanol to reduce radiation decomposition.

Adenosine-5'-triphosphate-γ-P32 (sodium salt)
up to 2,500 mCi/mmol. Prepared monthly and usually available from stock. Supplied in 50% aqueous ethanol to reduce radiation decomposition.

Adenosine-5'-triphosphate-γ-P32 (ammonium salt)
about 20,000 mCi/mmol at time of preparation. Prepared monthly and usually despatched immediately. Supplied as the freeze-dried salt.

All three products are very competitively priced and in convenient package sizes.
For full details please contact:

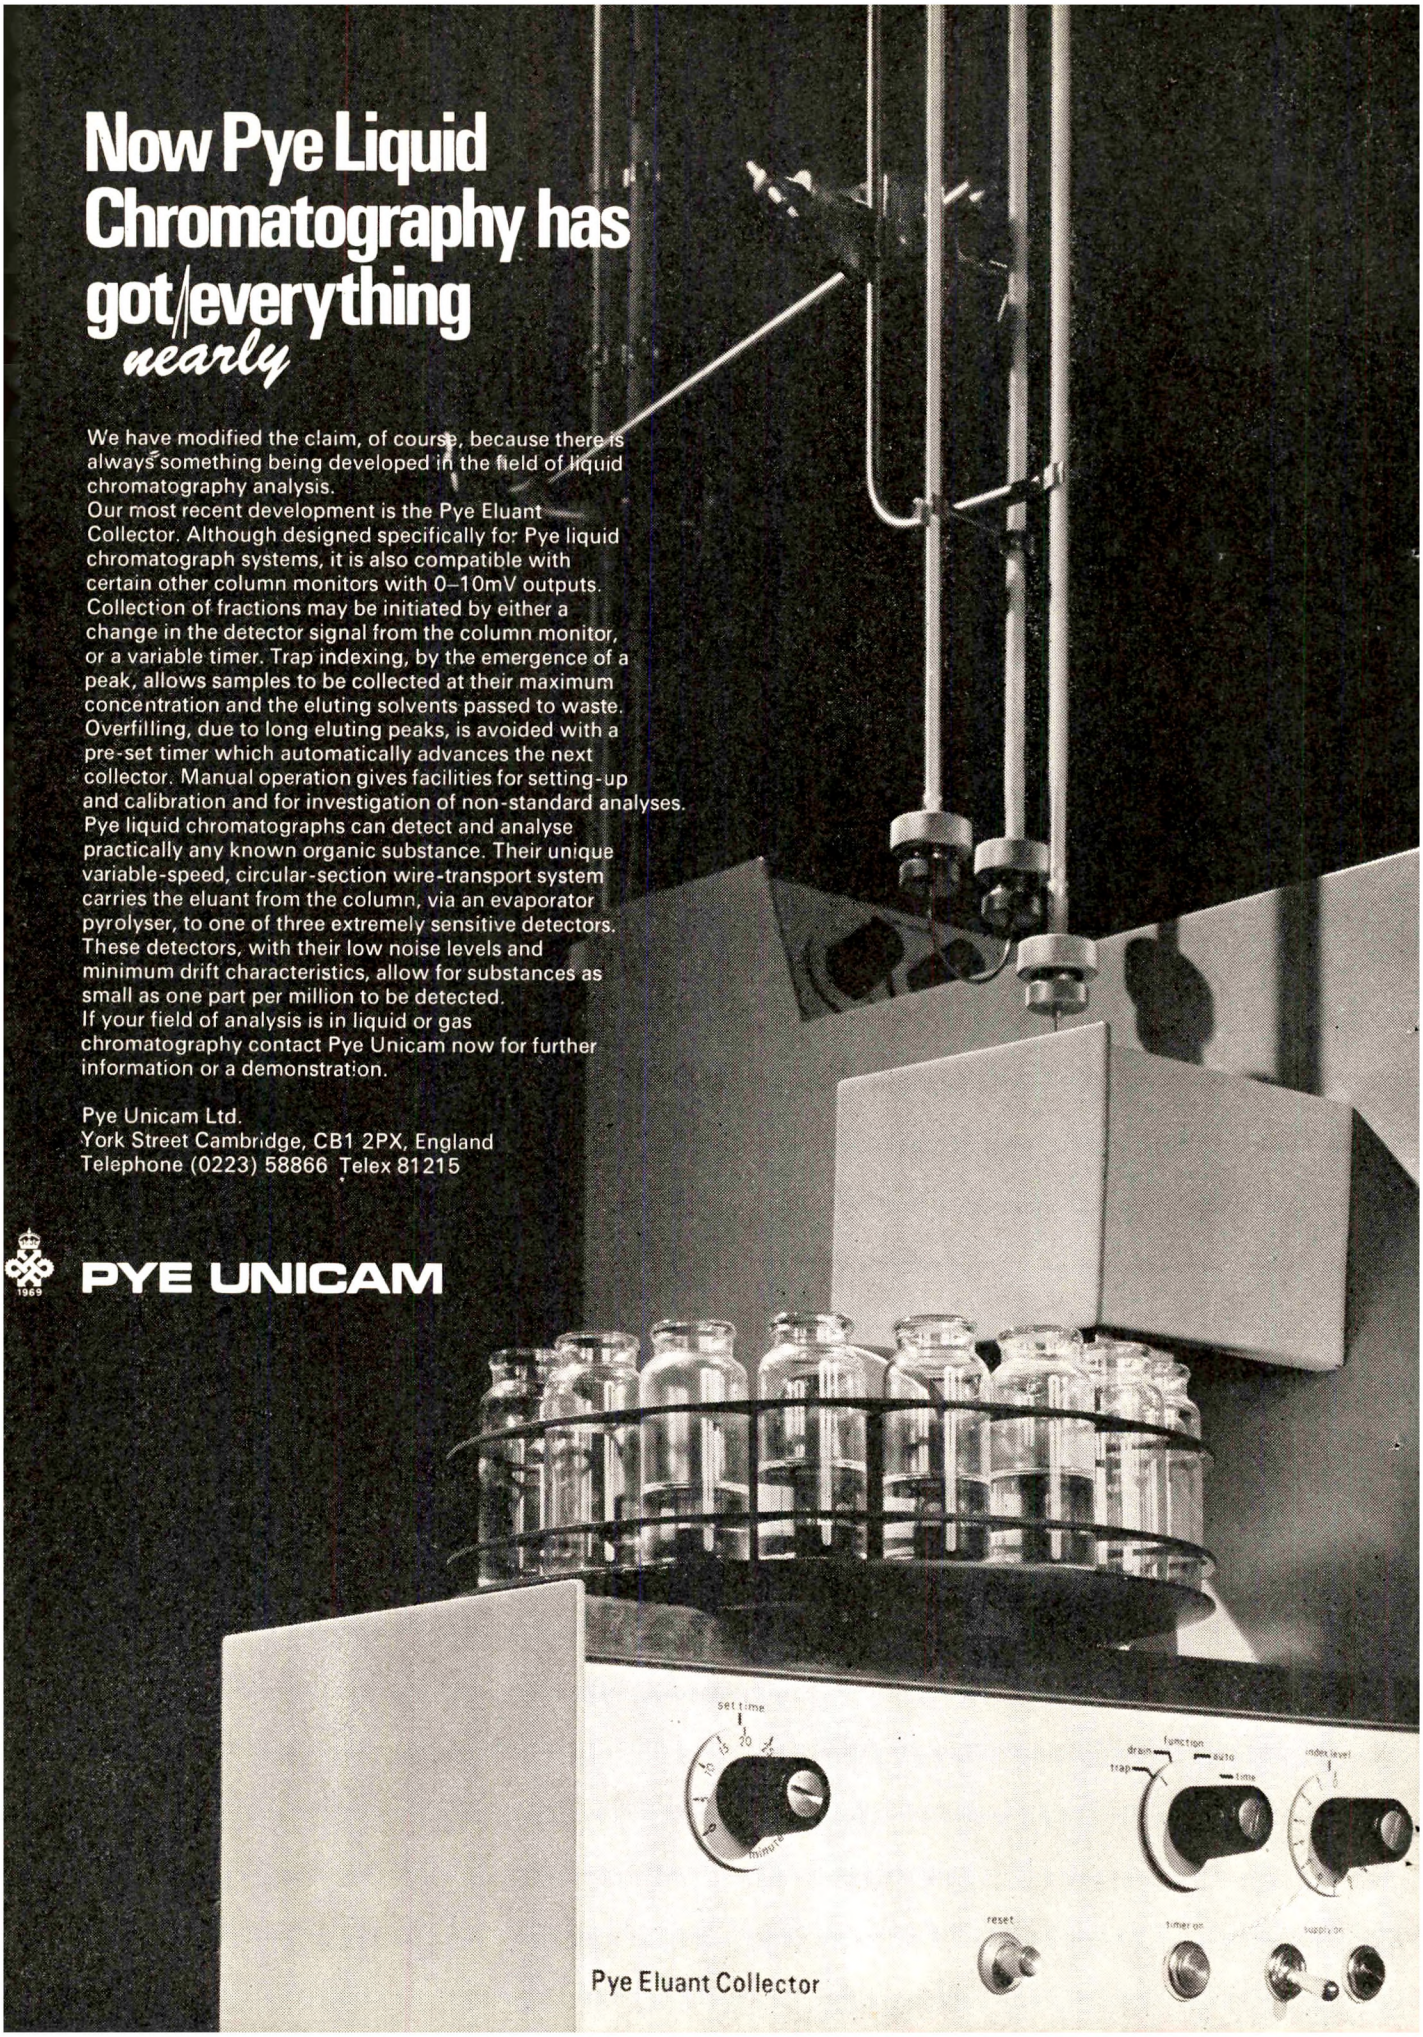
RECENT SCIENTIFIC AND TECHNICAL BOOKS xix



(Continued overleaf)

Now Pye Liquid Chromatography has got everything *nearly*

We have modified the claim, of course, because there is always something being developed in the field of liquid chromatography analysis.
Our most recent development is the Pye Eluant Collector. Although designed specifically for Pye liquid chromatograph systems, it is also compatible with certain other column monitors with 0–10mV outputs. Collection of fractions may be initiated by either a change in the detector signal from the column monitor, or a variable timer. Trap indexing, by the emergence of a peak, allows samples to be collected at their maximum concentration and the eluting solvents passed to waste. Overfilling, due to long eluting peaks, is avoided with a pre-set timer which automatically advances the next collector. Manual operation gives facilities for setting-up and calibration and for investigation of non-standard analyses.
Pye liquid chromatographs can detect and analyse practically any known organic substance. Their unique variable-speed, circular-section wire-transport system carries the eluant from the column, via an evaporator pyrolyser, to one of three extremely sensitive detectors. These detectors, with their low noise levels and minimum drift characteristics, allow for substances as small as one part per million to be detected.
If your field of analysis is in liquid or gas chromatography contact Pye Unicam now for further information or a demonstration.

150th Year Catalogue with interesting historical notes from 42 Drury Lane, London WC2

BS Precision Instruments

The Jamin Refractometer

The Jamin refractometer employs two interfering light beams reflected from the surfaces of two thick glass blocks; one beam passing through the reference material, the other through the sample. Any difference in path length due to a difference in refractive index is indicated by a shift in the interference pattern at the eyepiece. The fringe centre may be restored using the compensation plates which may be calibrated to yield the path difference and hence the difference in refractive index. Although primarily intended for measurement of gases to approximately 1 part in 1 million, the instrument may also be used for transparent liquids.

We now have capacity for aluminising certain types of mirrors, at short notice.

Handbook of Geochemistry

Executive Editor: K. H. Wedepohl. Editorial Board: C. W. Correns, D. M. Shaw, K. K. Turekian, J. Zemann

Vol. II/2

Second Instalment. With 105 figures. VI, 667 pages. 1970
Loose-leaf in clothbound binder
DM 212,—

Subscription price (applicable on orders for the complete Handbook)
DM 169,60

Springer-Verlag
Berlin-Heidelberg-New York

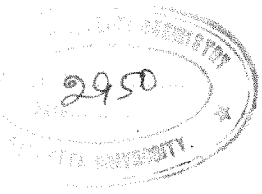
The Handbook of Geochemistry offers a critical selection of important facts about the distribution of the chemical elements and their isotopes in the earth and the cosmos. Approximately 70 specialist authors have made this selection from the flood of information which resulted from improved investigative methods. The data are set out in the main part of the Handbook (Vol. II) in tables and diagrams as an integral part of extensive discussions on abundance, distribution and behavior of the elements. As this book plainly shows, geochemistry and cosmochemistry are intimately linked with a number of other disciplines.

With the exception of the general part (Vol. I), the work is arranged according to the atomic numbers of the elements, each chapter being organized in exactly the same way. Thus, the reader will find such frequently needed information as the crystal chemical properties of an element, or its occurrence in meteorites or metamorphic rocks, under the same section in each of the 65 chapters. The loose-leaf system enables the contributions to be published in random order, regardless of their position in the book, and revisions to be made as desired.

Journal of Microscopy

Edited by G.A. Meek, R. Ross and G.C. Amstutz

The *Journal of Microscopy* (formerly *Journal of the Royal Microscopical Society*) is an international journal with a distinguished editorial board. Its purpose is to provide rapid publication of review articles, original research papers, short technical notes and letters to the editors in the fields of light, electron, X-ray, field ion and all other forms of microscopy. In 1969 the Journal also became officially associated with the International Society for Stereology and as a result the journal's scope has been widened to deal with the analysis of textures and structures in space.



Published bi-monthly at 52s ($8.00) per issue; subscription price £15 ($45.00) per annum, post free.

Now Pye Liquid Chromatography has got everything *nearly*

We have modified the claim, of course, because there is always something being developed in the field of liquid chromatography analysis.
Our most recent development is the Pye Eluant Collector. Although designed specifically for Pye liquid chromatograph systems, it is also compatible with certain other column monitors with 0–10mV outputs. Collection of fractions may be initiated by either a change in the detector signal from the column monitor, or a variable timer. Trap indexing, by the emergence of a peak, allows samples to be collected at their maximum concentration and the eluting solvents passed to waste. Overfilling, due to long eluting peaks, is avoided with a pre-set timer which automatically advances the next collector. Manual operation gives facilities for setting-up and calibration and for investigation of non-standard analyses.
Pye liquid chromatographs can detect and analyse practically any known organic substance. Their unique variable-speed, circular-section wire-transport system carries the eluant from the column, via an evaporator pyrolyser, to one of three extremely sensitive detectors. These detectors, with their low noise levels and minimum drift characteristics, allow for substances as small as one part per million to be detected.
If your field of analysis is in liquid or gas chromatography contact Pye Unicam now for further information or a demonstration.

ADVANCES IN BIOCHEMICAL PSYCHOPHARMACOLOGY,
VOLUME I

Edited by E. COSTA, National Institute of Mental Health, and P. GREENGARD, Yale University School of Medicine

1970. 238 pages. Hfl. 51.–(119s.) ISBN 0 7204 4061 0

These provocative and well-documented papers, originally presented at the 7th Annual Meeting of the American College of Neuropsychopharmacology in December, 1968, cover the important modern aspects of neurochemistry and neuropsychopharmacology.

BIOCHEMISTRY OF SIMPLE NEURONAL MODELS

Edited by E. COSTA, National Institute of Mental Health, and R. GIACOBINI, Karolinska Institutet, Stockholm

1970. 384 pages. Hfl. 60.–(140s.) ISBN 0 7204 4078 5

This volume contains papers and discussion presented at the Second International Meeting of the International Society of Neurochemistry (I.S.N.) The major research trends of the molecular biology of nervous activity are represented by accounts of current research in the laboratories of some of the world's leading biochemists, pharmacologists and physiologists.

(*Volume II in the series "Advances in Biochemical Psychopharmacology"*)

ROLE OF CYCLIC AMP IN CELL FUNCTION

Edited by P. GREENGARD, Yale University School of Medicine, and E. COSTA, National Institute of Mental Health.

1970. 390 pages. Hfl. 63.–(147s.) ISBN 0 7204 4079 3

Cyclic AMP is known to play a major role in the physiology of virtually every organ in the body. It has also been shown to be of great importance in the regulation of the central nervous system, and it is in this area that research has been expanding most rapidly.

The Nature of Light

VASCO RONCHI, *Director, Instituto Nazionale di Ottica, Arcetri, Florence*

Translated by

VINCIO BAROCAS, *Director, Jeremiah Horrocks and Wilfred Hall Observatories, Preston*

A major survey, by an international authority, of the study of light, from thoughts of the Graeco-Roman philosophers through the Middle Ages, the Renaissance, and the great discoveries of the seventeenth century, to the latest research findings of the present. Lavishly illustrated with numerous colour and black and white photographs this is likely to remain a standard work for many years.

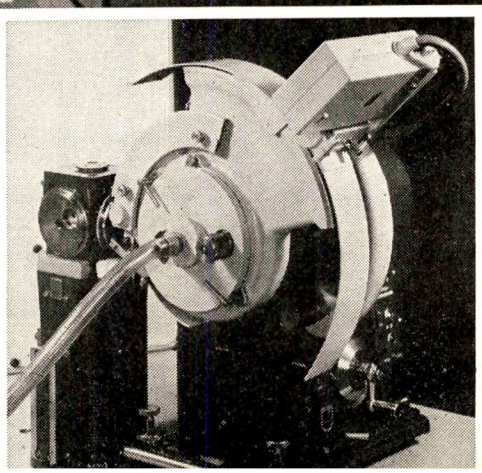
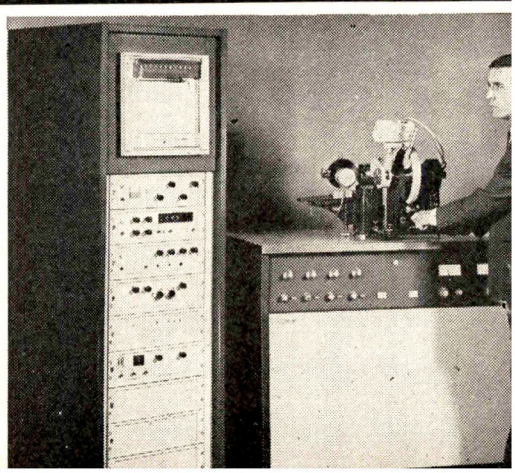
What do you want in X-ray diffractometry?



PHILIPS



People with problems in X-ray diffractometry are very important to the design of Philips X-ray diffraction equipment. After all, if we do not know the problems you are facing, how can we produce the right instruments ? But this information alone is not enough. It needs the backing of Philips' own technological experience and vast research effort. The result is a range of equipment that is the most advanced of its type.
Look at what is available for industry and research. Three models of 3kW generators, vertical and horizontal goniometers with diffraction sets, Debye-Scherrer and universal flat plate cameras with all the accessories, high-temperature attachment, automatic sample changer, texture attachment, metallurgical kit, Eulerian cradle, vacuum attachment, auto-focus specimen holder, detectors, tubes, circuit panels – exactly what you want in X-ray diffractometry. And when you suggested a computer-controlled instrument we had the answer in the PW1100 single-crystal diffractometer – complete with all the software you normally have to provide yourself. The fact is, by helping us we are helping you to keep way out in front in X-ray diffractometry. Get the full story from Pye Unicam Ltd – write for free brochures today.

Core and Cube Cutting Machine

Cuts Cores up to 2¾″ dia. x 5½″ long — Produces Cubes from ¾″ to 1¾″

Model GSP 250

This machine is designed to cut opposite ends of cores parallel and square to the longitudinal axis. Once the core is clamped in position in the vee block location the first cut is made with the cross slide rule calibration at zero, then the cross slide is moved from right to left and the cross slide rule is set to length of core required and the opposite end is cut, the core remaining clamped throughout the whole procedure.

Long cores can be cut by using all three vee block clamps. The 5½″ maximum length is the longest length that can be cut without moving the core or reversing it in the vee block locations. By reversing, any length can be cut, accuracy of parallel of the cut faces can not be maintained due to the slight variation of location at different parts of core diameter.

Models in Structural Inorganic Chemistry

A. F. WELLS

Most inorganic compounds exist as solids made up of repeating patterns of atoms. For a proper understanding of their structures and their formulae the student should study, or build for himself, three-dimensional models. This book describes the construction of models of the most important types of inorganic compounds, using a set of units devised specially for the purpose. It and the accompanying model-building kit should be valuable not only in teaching chemistry in universities but also in such related subjects as metallurgy and mineralogy.
133 text-figures 55/- paper covers 28/-
Model-Building Kit £25

An Introduction to the Theory of Functions of a Complex Variable

E. T. COPSON

This book provides an introduction to the methods of the theory of functions of a complex variable. The topics covered include the properties of one-valued differentiable functions of a complex variable, the problem of conformal representation, the elements of the theory of integral functions, the behaviour of some of the special functions of analysis, and the classical proof of Picard's Theorem. This paperback edition replaces the hardback version first published in 1935.
Paper covers 30/- *Oxford Mathematical Monographs*

Experimental Crystal Physics

W. A. WOOSTER and A. BRETON

Simple experiments in this field are helpful for students, and this edition continues the tradition of the first in presenting experiments that can be performed in two or three hours. New topics covered include dielectric constants, dynamic measurements of piezoelectricity and elasticity, the growth of crystals, semi-conductors, the Hall effect, ferroelectricity, and ferrimagnetism.
Second edition 12 plates 63 text-figures 60/-

Signals for Survival

N. TINBERGEN, H. FALKUS, and E. A. R. ENNION

This book, based on the film of the same title that was awarded the 1969 Italia Prize for television documentaries, describes and interprets in simple terms the sign-language of a common seabird, the Lesser Blackbacked Gull. A successor to *Tracks* (28/-), this book has a more scholarly aim, and represents a carefully chosen example of the modern approach to the study of the animal in its world. 80 photographs and drawings throughout 40/-

Complementary Variational Principles

A. M. ARTHURS

The approach of this introduction to complementary variational principles, which are used to obtain upper and lower bounds for the solution of a variational problem, is based on the canonical form of Euler-Lagrange variational theory. The book deals with the theory of the simplest problem in the calculus of variations, its extension to a certain class of differential, integral, and matrix equations, associated variational problems, and some applications of the general theory to particular kinds of linear and non-linear boundary-value problems. 40/- *Oxford Mathematical Monographs*

Electronics for Nuclear Particle Counting

Edited by **L. J. HERBST**

This book covers the general principles of nuclear particle analysis and concentrates on the design of electronic nucleonic instrumentation. It is based on a course given by members of the Electronic and Applied Physics Division of the A.E.R.E. Harwell, and should be useful both to designers and users of nucleonic instrumentation. 4 plates 294 text-figures
paper covers £5/10/- *Harwell Post-Graduate Series*

SCIENCE AND ENGINEERING POLICY SERIES

Engineers and Engineering

LORD HINTON of BANKSIDE, K.B.E.

Changes in the system of training engineers are being made so quickly that it is difficult to judge whether the engineers produced will be better or worse than their predecessors. This book discusses these changes, the work of engineers, and their relationship with science, management, and government. Paper covers 12/-

Innovations

Scientific, Technological, and Social

DENNIS GABOR

The author gives a critical preview of 137 creative novelties that can be expected in the next fifty years. These include technological inventions, biological novelties, and socio-economic reforms. Most of the more important technological and biological novelties, though beneficial in their main purposes, are likely to have serious social side-effects; the author has therefore listed reforms with which society might defend itself against the unstabilizing consequences. Paper covers 15/-

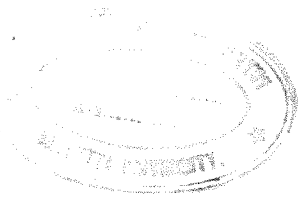
Unicam UV Spectrophotometers make light work

What does this mean to you ? In research, results you can trust and repeat. In routine applications, error-free operation by the least experienced member of your staff.

When you come to Pye Unicam, even the selection of your UV spectrophotometer is simple. There is a choice of instruments broad enough to meet your every requirement and to match your budget, with a staff of experienced application specialists to back them up.



Just look at what is available . . .
SP500 Series 2 and **SP600 Series 2** quantitative single beam spectrophotometers, **SP700** for research, **SP1800** for low-cost double-beam operation, **SP3000** automatic digital instrument, **SP8000** for the ultimate in flexibility, and the **SP1300 Series 2** low-cost colorimeter.

Write or 'phone for free information today. That's simple too, isn't it.

ANNOUNCING
2 NEW JOURNALS FROM plenum PUBLISHING CORPORATION

GENERAL RELATIVITY AND GRAVITATION

A Journal of Studies in General Relativity and Related Topics published under the auspices of the International Committee on General Relativity and Gravitation (GRG).

Edited by **André Mercier,** *Professor of Theoretical Physics and Philosophy of Science, Institute of Theoretical Physics, Sidlerstrasse 5, CH-3012 Berne, Switzerland.*

Aims

- Publication of research papers on topics related to GRG.
- Surveys and review articles on current research in GRG.
- Details of GRG Conferences and other enterprises of interest to scientists working on GRG.
- Book reviews.
- Comprehensive bibliography and biographic reports, published as continuation of the Bulletin GRG.

Sample copies A free sample copy of Volume 1, Number 1, 1970, is now available from the publisher, Plenum Publishing Company Ltd., Donington House, London, W.C.2. Tel. 01-836 5238.

Subscriptions Annual subscription: Volume 1, 1970/71 (4 issues), 215s. ($26.00). Add 9s. ($1.10) for postage. Full descriptive leaflet available on request from the publisher.

JOURNAL OF CRYSTAL AND MOLECULAR STRUCTURE

An International Journal of Crystallographic and Spectroscopic Studies of the Structures of Crystals, Molecules and other Atomic Assemblies.

Edited by **M. F. C. Ladd,** *Department of Chemical Physics, University of Surrey, Guildford, Surrey, England.*

Editorial Board P. T. Beurskens • C. H. Carlisle • H. P. Fritz • G. Kartha • J. C. Leyte S. F. Mason • A. McL. Mathieson • D. Rogers • I. G. Ross • J. Trotter G. A. Webb

JCMS publishes reports of original research in the form of both full-length *articles* and *short* communications, but does not publish either *letters* or *book reviews.* The journal addresses itself not only to crystallographers and spectroscopists, but also to chemists, physicists, biochemists, biologists and all others who seek and use the results of structural investigations.

Subscriptions Annual Subscription: Volume 1, 1971 (6 issues), 250s. ($30.00). Add 15s. ($2.00) for postage. Subscription orders should be sent to Plenum Publishing Company Limited, Donington House, 30 Norfolk Street, London, W.C.2.

Contributions to either journal should be sent directly to the appropriate editor. For sample copies, contents of forthcoming issues, descriptive leaflets, please write to the publisher.

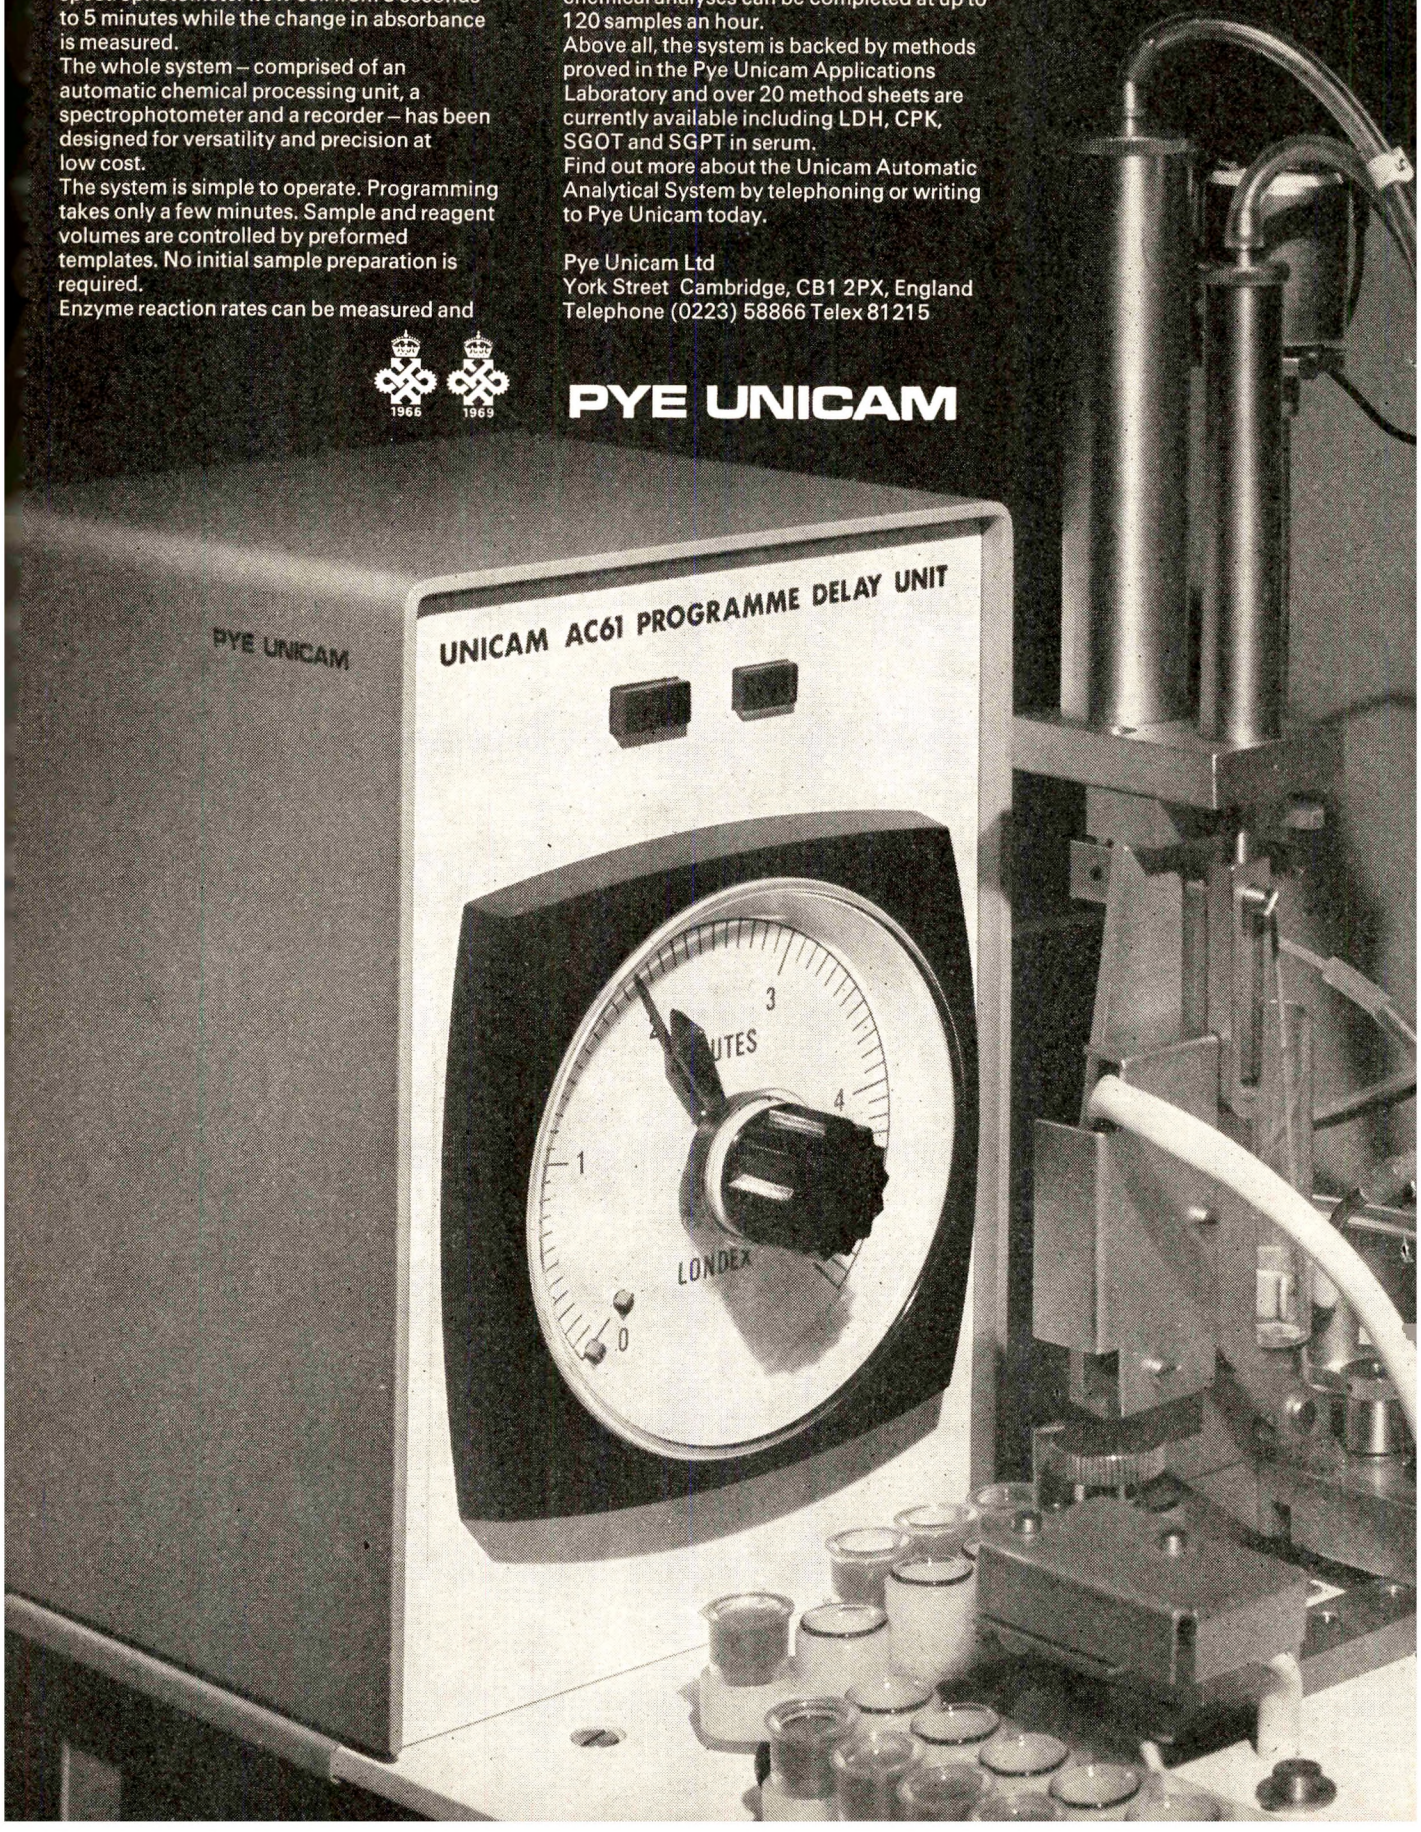
(Continued overleaf)



Pye Unicam has a new automatic enzyme analyser. This is what makes it tick.

It is the new Unicam AC61 Programme Delay Unit, which holds the reacting mixture in a spectrophotometer flow cell from 5 seconds to 5 minutes while the change in absorbance is measured.
The whole system – comprised of an automatic chemical processing unit, a spectrophotometer and a recorder – has been designed for versatility and precision at low cost.
The system is simple to operate. Programming takes only a few minutes. Sample and reagent volumes are controlled by preformed templates. No initial sample preparation is required.
Enzyme reaction rates can be measured and recorded completely automatically at speeds ranging from 12 – 60 an hour, while other chemical analyses can be completed at up to 120 samples an hour.
Above all, the system is backed by methods proved in the Pye Unicam Applications Laboratory and over 20 method sheets are currently available including LDH, CPK, SGOT and SGPT in serum.
Find out more about the Unicam Automatic Analytical System by telephoning or writing to Pye Unicam today.

Guess what...

Inspired guesswork has its place in the advancement of science. On the well-defined level of organic analysis, however, guesswork is, at the very least, a time-wasting irrelevance. All the uncertainties are eliminated by the performance of the MS902S double focusing mass spectrometer. The MS902S offers:-

Ultra high resolution guaranteed at greater than 100,000 . . . An accuracy of 2 ppm in mass measurement . . . Fast scans at high resolution in only 8 seconds . . . Spectra for automatic data processing from gas chromatograph eluents . . . Intense, well-defined metastable peaks . . . Four inlet systems attachable directly and individually to the ion source . . . A sample handling capacity as little as 1 nanogram . . . A wide range of accessories for comprehensive versatility . . . A simplicity of controls that makes operation child's play . . .

Considering these features, why be left guessing? Spare yourself the tedious search for confirmation—which may, or may not, be forthcoming. Install an MS902S and be absolutely certain.
Services include installation, instruction, consultancy and world-wide spares availability.

Guess nothing!

with the MS 902S

The world's most highly developed mass spectrometer

RECENT SCIENTIFIC AND TECHNICAL BOOKS xix

(Continued overleaf)

We made a successful atomic absorption spectrophotometer –then we made it even better

And that's exactly what Pye Unicam did with the world-famous Unicam SP90 Atomic Absorption Spectrophotometer. It's now the Unicam SP90 Series 2, but it's not just the name that has changed. Absorbance or energy scales can now be presented in linear form on the integral meter or on a pen recorder, with continuous scale expansion of up to 10x for absorbance. Results can also now be shown on a digital display and printout accessory. The sensitivity specification has been increased as a result of improved hollow cathode lamps and excellent optical quality, whilst still preserving the outstanding detection limits. And, of course, there are all the first-class features and accessories associated with the original SP90 spectrophotometer– like flame emission facilities, a wide choice of flame and burner systems (including nitrous oxide with a new burner head), a three-lamp turret and automatic sampling. For more information and full technical details on this new instrument and the range of hollow cathode lamps, write to Pye Unicam Ltd.

Foreign information?

For many years we have been quietly providing the vital translations into English without which many of our leading companies would be unable to continue their international activities.

Most aspects of modern research and development are covered, with particularly strong resources in the field of medicine and pharmaceutics. Translations are carried out by subject specialists, in order to ensure absolute authenticity of terminology.

BS Precision Instruments

We now have capacity for aluminising certain types of mirrors, at short notice.

SOLE DISTRIBUTORS IN U.K. OF SCHOTT INTERFERENCE FILTERS

Polarimeter Model P.70

A long time has been spent developing this photo-electric polarimeter, and we are now satisfied that it will please the most discerning user. It has the accuracy of rotational measurement that can only be achieved from a ruled circle, plus independent magneto-optical compensation for recording or digital presentation, should it be required.

There are four models from which to choose, all virtually identical in external appearance, but with internal variations to provide the particular facilities that you require.

Green Paper to Burn

At the Conservative Party conference next week, the new British Government must finally declare itself on science and technology. Some hesitation in bringing forward new policies may be understandable and even seemly, but the point is now approaching when the government will lose the initiative and even its reputation if it allows uncertainties about future organization to persist. Several related issues need to be decided. There is the organization of government laboratories, called into question by Mr Wedgwood Benn's Green Paper and by the protests which it occasioned from the directors of laboratories concerned and from organizations such as the Confederation of British Industry, the present Minister of Technology's old stamping ground. There is the question of how the research councils should be related to each other and financed, and a host of important if tactical questions such as British membership of the project to build a 300 GeV proton accelerator beneath the CERN umbrella—Mrs Margaret Thatcher's trip to Geneva last week with Sir Brian Flowers as usher is probably a sign of which way the wind is blowing. Finally, there is a whole complex of questions about the organization of universities and, for example, their relationship with the polytechnics. Until something is said, the new government cannot boast of having a policy for science, technology and higher education.

On the government laboratories, the first need is somehow to resolve the uncertainties which have been generated by Mr Wedgwood Benn's Green Paper and its aftermath. What is the government to do? One obvious need is to complete the reorganization of the Atomic Energy Authority begun in 1968 and now suspended in uncertainty. Although the decision to saddle private industry with responsibility for the development of fast reactors should delight the Conservatives on ideological grounds, there is a risk, to say the least, that private industry will not be able to handle the development of fast reactors if, through no fault of the companies now engaged in this work, the problem of making economic reactors turns out to be more difficult than the optimists now expect. A modest insurance policy would seem to be worth while, which in turn implies that there should be continued government involvement in nuclear power developments. This is where the new government may have to work over its predecessor's thinking a second time. The arrangements which have been suggested for the organization of the fuel company are sensible enough, but nothing has yet been decided about the future of Aldermaston, which really ought to become a defence research establishment pure and simple. And the problem of Harwell persists—is it really going to become a successful freelance research association and, if so, should it remain within the present hierarchy of research establishments?

These tactical questions provoke more general considerations of the function of government laboratories as such. Obviously there is a need for some housekeeping. Defence research is an obvious claim on public funds. So too are laboratories such as the National Physical Laboratory, which have statutory as well as useful functions to perform. To be sure, it is important that in the management of these establishments, the best use should be made of scarce resources and of the opportunities which present themselves. Although there is no reason why defence research should decline in volume with the decline of expenditure on military equipment—the correlation might even go the other way—there is every reason to hope for considerable savings in the present pattern of defence research in Britain. Protestations to the contrary notwithstanding, it is exceedingly hard to believe that the Royal Aircraft Establishment at Farnborough, the Royal Radar Establishment at Malvern, the Atomic Weapons Research Establishment at Aldermaston, the Signals Research Establishment at Christchurch and a dozen other smaller defence laboratories can be at present fully stretched by the needs of the defence programme. Is this not a case in which the electronically inclined defence establishment could be made into a nucleus of a research organization for carrying out the long-term development of telecommunications which the new Post Office Corporation will be wishing, a decade from now, that it had carried out? One proper and important function of the complex of government laboratories is, after all, precisely to look after the development of fields of technology in which there is some realistic hope of long term benefit.

But what kind of organization will best suit the needs of government intervention in civil research and development under a Conservative government? Temperamentally, the new ministers will wish to give industry as much freedom as possible, but there is a limit to the extent to which *laissez faire* principles make sense. Evidently there has to be some means of regulating the application of industrial standards. Evidently there has to be some device for making sure that the very large industrial companies are not the only organizations able to afford industrial research. Yet experience has shown that the pattern of the cooperative research association is often unhelpful. Will the Conservatives choose to follow the United States Government in providing indirect subsidies to private industry by means of contracts for the supply of publicly required machinery or will they follow the traditional Labour method of helping causes con-

sidered to be good? Both instruments of intervention have their defects. Indirect subsidies by means of contracts are easier to provide in some fields (such as aircraft technology) than in others. And even well-meaning governments can make bad decisions about desirable goals in technology. Even though the new Conservative Government may be spending a comparatively small part of the GNP on the support of industrial research and development, it is important that it should find an equitable administrative machine for doing this. Quite possibly, the best instrument would be an extension of the research council technique towards the industrial field or, in other words, a straightforward application of what used to be spoken of as the Industrial Research and Development Authority in the days of the Trend Report, in the early sixties. Of the decisions which are required in the channelling of government support towards industrial research and development, the creation of suitable machinery is the most urgent need.

It goes without saying that the most ineradicable of any British Government's functions in the support of science and technology must be in the support of higher education and here it must sadly be acknowledged that Mrs Margaret Thatcher has done very little to give her voters and taxpayers confidence. Too willingly, she has been prepared to support the Labour Government in its mistakes. On July 23 this year, Mrs Thatcher went gratuitously as far as to say that "we endorse the role of the polytechnics as outlined in the White Paper of May 1966". By doing so, she has made it more difficult to see how the new government can bring about an easy relationship between the universities and the poor cousins by whom they are surrounded. Yet the present system in which the polytechnics and the universities are supposed to coexist in parallel should be on simple political considerations an offence against everything for which the Conservatives stand. First of all, the separation of these two instruments of higher education is meant to be a device for distinguishing between the academic sheep and the technical goats. Is this really consonant with the notion that the modern world is everybody's oyster? Second, the polytechnics are a burden on the rates. Does Mrs Thatcher wish to become known as the person who shed the burden of higher education from central government to the local authorities? And finally, of course, the polytechnics seem destined to be impoverished of people for teaching and of money for facilities. Is this consistent with the idea that higher education is the pursuit of excellence? In short, if Mrs Thatcher listens to what her colleagues say about the importance of education, she will either abolish the polytechnics altogether or —if she has sense as well as a capacity to hear—will merge them with the universities.

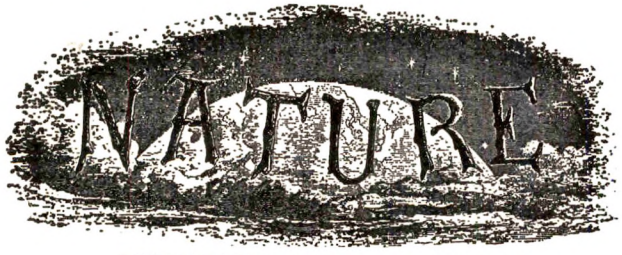
The issue is important because it affects the way in which young people will be educated in the remainder of this century. It is important for practical reasons because it affects the way in which the research councils must function in the years immediately ahead. To begin with, there are anomalies in the way in which at present the research councils enjoy an autonomy within a carefully restricted frame of reference. The Science Research Council, for example, is free to make research grants only within the United Kingdom and only so long as its activities seem not to conflict with those of other research councils or government departments. Although the research councils have an important influence on the pattern of university research, their influence is by no means decisive. Evidently, to tell from the experience of the past few months, the research councils are not their own masters when it comes to deciding whether to spend money on schemes such as the new proton accelerator at CERN. This, as it happens, is a field in which a rigorous application of the Conservative ideology might lead Mrs Thatcher and her colleagues to a position easily acceptable within and outside the government. For would it not make sense to arrange that research councils should be free to spend money where they choose? If the Science Research Council, for example, has set its heart on contributing towards the CERN machine, if it considers that such an expenditure would be in the British interest and if it believes that such a contribution could be made without losing the allegiance of physicists in British universities, is there not a case for letting the money be spent? To be sure, a prudent Science Research Council, edging its way towards such an expenditure of money would undoubtedly take care that the reasons for the expenditure were plainly understood, but that in itself would be a gain and not a loss.

Unhappily, no government can be relied upon to find its way towards these truths by its own devices and it must be admitted even by the present government's enemies that the quality of the advice available to British governments is at present poor. The amount of it is quite inadequate. The Council for Scientific Policy, which could well by now have seized the initiative for deciding issues of importance, such as the way in which the universities and the polytechnics should be related, has spent two placid years in the contemplation of its own future. Quite possibly, the new chairman, Dr F. S. Dainton, will turn out to be a heroic source of counsel, but he will need time to find his most economical stride. And it seems plain that the Central Advisory Council on Science and Technology under Sir Solly Zuckerman is living through a similar period of uncertainty. What will its function be in 1971? Will it still be in business then? Coupled with uncertainties about the future of the Ministry of Technology, these administrative difficulties are bound to sap morale. Good government requires that more permanent arrangements should be made. The trouble is that under the pattern of government which has grown up in Britain, no single minister can hope to have the power of disposition within his own control. Will Mr John Davies, Mrs Margaret Thatcher and even their more senior colleagues have the wit to see the urgency of the task they have so far neglected? Next week should tell.

New Planning for Planners

THE Council for the Protection of Rural England, not conspicuous for its adventurousness, has made in the past few days a sensible protest about the immunity of public authorities in Britain from the restrictions to which ordinary mortals are subjected by planning regulations and authorities. As part of its contribution to European Conservation Year, the council set out some months ago to study the problems created by the pursuit of familiar civilized objectives—agriculture, power generation, the construction of roads, the recovery of minerals and the conservation of water. The upshot seems to have been the setting up of working parties which have now come out with independent but impressively harmonious complaints that much of the damage done to the environment by these familiar activities could be prevented if public authorities themselves were more ready to practise what they preach. Unhappily, there are several circumstances in which the planning legislation which, on the whole, has worked well in Britain, exempts public authorities from detailed control. Some years ago, the attempt by the South-East Gas Board to build a gas holder in the centre of the rural town of Abingdon drew attention to the nature of this problem (and such a torrent of protest that the gas board backed down). The problem now is to ensure that water undertakings are not always free to flood deserted valleys without first winning the consent of local planning authorities, that electricity utilities live by the same rules as other people and that local authorities also have a say about the manner in which mineral resources should be exploited. In the long run, a strengthening of the planning legislation will be sufficient.

The issue may well be brought to a head next week at the public inquiry due to be held about the development plan for Greater London conceived five years ago and published early in 1969. In its way, the plan is a landmark in the process of making planning more effective—it begins with an explicit statement by the Greater London Council about the need somehow to ensure that the population of London remains more or less what it is at present, which implies that deliberate steps must be taken to restrain the centrifugal tendencies of this among other urban populations. But the plan has also become a local source of contention for the way in which it involves the building of a network of urban motorways within the inner city. Is it right that houses should be knocked down to make room for motorways? Who, in any case, can be sure that the city council is the best judge of what the future will require? May not the ideal pattern for a city of the next century be radically different from the uniform distribution of dwelling houses and offices over the face of south-east England?



University Unrest Persists

THE Scranton Commission (see page 8) has produced a worthy and even a sober report. It could well have been a more disturbing document if there had been time for the members of the commission to digest the news of the explosion in the mathematics building at the University of Wisconsin on August 24 (see *Nature* **227**, 1085; 1970), which has cast a gloom on the American academic world. At the beginning of the new academic year, the question is not so much whether decent government can bring students and faculty together but whether universities as institutions can hope to survive in the face of all the uncertainties which at present surround them. The fearful loss of good men as university presidents, and the haunting difficulty of replacing them, is one obvious symptom of the present crisis. Beyond that, however, lies the question whether the student body will recover from the upsets of the past few years. The Scranton Commission is both liberal and humane in its appraisal of the immediate problem of how to make American campuses more peaceful. It may have underestimated the extent to which the changes now under way may bring radical upheaval of the teaching pattern in the years ahead.

To be more careful about the mixing of government and university business is, of course, a good objective. So too is the commission's recommendation that public officials—no doubt Mr Agnew is the name that comes most easily to mind—should consider more carefully the effect of their public pronouncements on the tension in the universities. It will be a blow for Mr Nixon that the commission should have pointed out that an ending of the war in South-East Asia would be one of the best ways of ensuring peace in the universities as well, but that has been self-evident for a long time even if, by now, the war is more a catalyst than a cause. The idea that university programmes for the training of military officers should be abandoned will also be a blow for the American Government but by no means a serious one. There are other ways of making soldiers than this. The notion that National Guardsmen should be better trained is sensible enough, but so familiar that it can hardly be counted an important component in the commission's report. The belief that the Administration itself, and the President in particular, can "exercise reconciling moral leadership" and thus help to keep the universities in order is not the strongest part of the Scranton Commission's report. The objective should rather be to find some way of making sure that the university system does not shake itself to pieces whenever the students and the President are at loggerheads.

The weakest part of the Scranton Commission's report is that which deals with the university. It is all very well to ask that university faculties should acknowledge the need for qualitative changes to accommodate the much larger numbers of students now clamouring for university places—the essence of the difficulty with which faculties are confronted is that of reconciling flexibility and firmness. In the past few years, a great many universities have leant over backwards to give students what they ask for—meaningless courses on subjects such as Black studies, for example—and have in the process lost their self-respect. There is a point at which a university faculty should insist on its competence to teach only what it knows, and thus deny the Spockian view that a university should by definition be able to provide all young people with whatever they may want. The essence of the present conflict between the universities and their customers—the students—is that the interests of both sides are in genuine conflict. Whatever the effects of the Scranton Commission's report—and they are almost certain to be beneficial—there is no avoiding the tendency towards universities in which faculties and student bodies are increasingly isolated from each other. Whether in these circumstances universities will be as competent as in recent decades to provide students with a vocational training of great value to industry, commerce or government is less certain. In short, the changes in the function of the American university which are now in prospect may go much deeper than the Scranton Commission imagines.

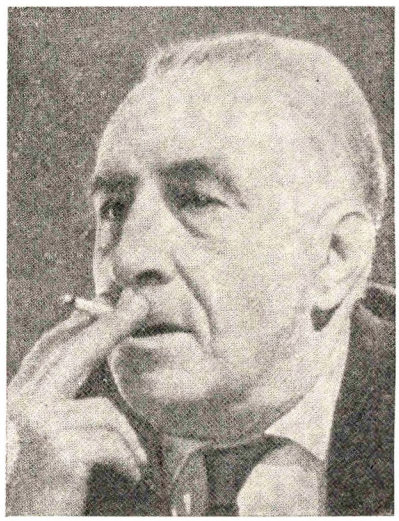
100 Years Ago

SCIENTIFIC ADMINISTRATION

NO reflecting Englishman can contemplate the great events of the present time without desiring to extract from them such warnings and instruction as may be serviceable to his country in case she should be drawn into war. Accordingly the press teems with discussions on every branch of the military art. We leave these to others. In what respects the constitution, the discipline, the training, and the arming of one army are superior to those of the other, it is scarcely the function of this journal to point out. Taking the broad fact that the Prussian army has, up to the present point, proved itself superior on the whole to that of France, and indeed to any army that has ever existed—a fact that no unprejudiced person will deny—let us ascertain, if we can, whether there may not be recognised some one broad cause to account for so broad a fact.

From Nature, **2**, 449, *October* 6, 1870.

OLD WORLD



SOVIET UNION

Arrests and Reinstatements

by our Soviet Correspondent

THE wave of protests by scientists and intellectuals against the limitation of academic freedom by the Soviet state continues. The latest to be arrested is the mathematical physicist, R. I. Pimenov, who, according to underground sources, was recently arrested in Leningrad and is awaiting prosecution under the criminal code of the Russian SFSR on a charge of disseminating "falsehoods derogatory to the Soviet State and social system".

Pimenov, who is 40 years of age, is well-known for his monograph on *Spaces of the Kinematic Type*, which has appeared in print both in the Soviet Union and in the USA. The facts behind the charges against him are not easy to ascertain, but certain rumours have linked his case with that of geneticist Zhores Medvedev, forcibly committed to a Kaluga mental hospital earlier this year for circulating privately produced (*samizdat*) essays criticizing state interference in science and the censorship of private mail.

Nikolai V. Timofeev-Resovskii.

Happier news, however, has been received of another member of what may be termed the "Medvedev circle". In August 1969, Medvedev's friend and colleague, Nikolai V. Timofeev-Resovskii, at the Obninsk Institute of Radiology was forced into premature retirement on a minimal pension. Timofeev-Resovskii has always been a somewhat "doubtful" character to the authorities, in spite of an excellent record in the Soviet cause in the revolution and civil war, since, during the '20's and '30's he was working in Germany and was trapped there by the war. In spite of the fact that he played an active part in anti-Nazi resistance work, and his own son fell a victim to the SS, Timofeev-Resovskii was accused of being a collaborator and a German spy and was imprisoned for several years. Following his release, he had worked for some time as head of the section of general genetics and radiobiology in Obninsk. Unfortunately, in 1968, certain well-wishers, without his knowledge, proposed his election to the Academy of

Sciences. This drew considerable publicity and not only was his election quashed, but a campaign against him was started at the Party level. He was accused of being an "emigré" and a "Morganist", resulting in his premature retirement on a near starvation-rate pension.

Happily, Timofeev-Resovskii, winner of three major international prizes for genetics (The Darwin Plaque, (GDR), the Mendel Medal (Czechoslovakia) and the Kimber Prize (USA)), seems to have received a certain amount of rehabilitation in recent months. The current issue of *Priroda* (No. 8, 1970) publishing an article of his, "The Biosphere and Man", which is an expansion of a lecture delivered in February 1970, refers to him as now working at the Institute of Medico-biological Problems of the Ministry of Health of the USSR. If this news is correct, it can only be a favourable sign, similar in significance to Medvedev's own release from the mental hospital, after the wave of protests on his behalf by other campaigners for intellectual freedom.

ASTRONOMY

Collaboration in South Africa

A REMARK in the annual report of the Science Research Council that discussions between the SRC and the South African Council for Scientific and Industrial Research are making good progress seems to have been something of an understatement. The SRC announced last week that agreement has been reached "in principle" to merge the facilities at the Royal Observatory at the Cape and at the Republic Observatory in Johannesberg into a single station situated near Sutherland, some 250 miles north-west of Cape Town.

Although some facilities will be maintained at the Cape Observatory, the new station, which will be called the South African Astronomical Observatory, will be the chief observatory in South Africa. In the short term, the SRC and the CSIR will have little to gain from the venture, but in the long term it offers considerable scope for expansion—the two separate observatories, situated in the centres of large cities, are unsuitable for development.

The new observatory is expected to come into operation early in 1972, when it is hoped that three telescopes from the Cape Observatory and two from the Republic Observatory will have been moved to the site. It will function as an institute of the CSIR, but the SRC will retain some say in its policies through an advisory committee, consisting of representatives of the SRC and the CSIR. Sir Richard Wooley, the Astronomer Royal, and director of the Royal Observatory at Herstmonceux, Sussex, will retire at the end of 1971 to become the first director of the new observatory. The SRC at present spends about £125,000 a year on the Cape Observatory but expenditure on the new observatory could be as much as £200,000 a year.

Another statement in the SRC's annual report, that approval has been given to "investigations preliminary to consideration of a proposal to plan an accurately figured dish capable of operating in the millimetre band", has been couched in vague terms for good reason, it seems. Sir Brian Flowers, chairman of the SRC, pointed out last week that millimetre wavelength astronomy is one area of research which must regrettably be passed over because of lack of funds. The difficulty is that such a dish must be accurate to within about one-sixteenth of the wavelength under investigation and it therefore seems that the SRC has already made up its mind that construction of a fifty-foot dish to that sort of accuracy would be too expensive at present.

New Centre for NERC

MARINE pollution is to be the primary interest of a new institute which has been established by the Natural Environment Research Council (NERC). The Institute for Marine Environmental Research has been set up not only as a centre for new research, but also to bring together various projects already in progress in universities and other organizations, under the auspices of NERC. The new institute will eventually be housed at Plymouth, in a complex of research groups which is planned to include extensions to the existing Laboratory of the Marine Biological Association of the United Kingdom. The director of the institute will be Mr R. S. Glover, who will retain the directorship of the Oceanographic Laboratory of the Scottish Marine Biological Association in Edinburgh, which has been incorporated into the new institute.

The prime objective of the institute's research programme will be to provide a deeper understanding of the biological basis of the productivity of the oceans and the way in which they are influenced by natural changes and by human activity, which of course includes pollution. This will be done chiefly by monitoring long term changes in marine communities in relation to their physical environment. These studies are intended to complement those already undertaken by other organizations.

Within the new institute it is planned to extend the plankton surveys which were started in Hull in 1930 by Sir Alister Hardy, and which are now carried out from the Oceanographic Laboratory in Edinburgh. They are to be extended, and linked with environmental surveys developed in cooperation with universities and other organizations, to concentrate on inshore areas and estuaries which are susceptible to pollution. While the new buildings are being planned, the expenditure on monitoring at the Edinburgh laboratory will be increased from £150,000 to £250,000 a year.

PHYSICS IN FRANCE

Policy for Solids

A DEMAND that the French Science Research Council and physics departments throughout France should remedy the inadequacy of crystal growing facilities and of new materials has come from a French Government committee investigating the state of research on the physics of solids and liquids (*Prospective: Physique des Milieux Condensês, Le Progrès Scientifique*, No. 139;

Documentation Française, 4 fr.). The committee, headed by Professor J. Friedel of Orsay, has also some sharp criticism of teaching methods in French universities.

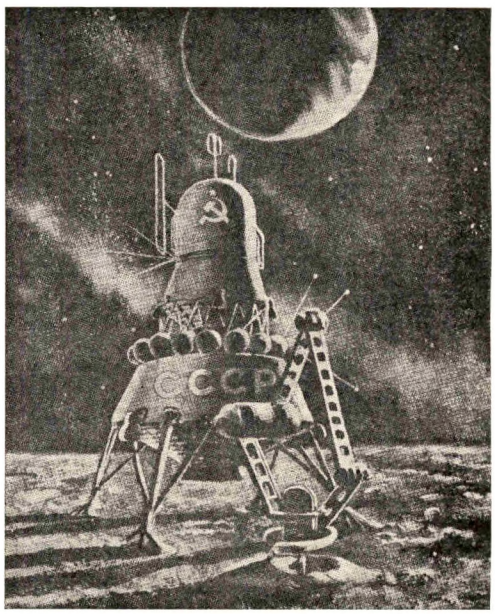
Why, the report proclaims, do physics departments persist in teaching undergraduates virtually nothing about simple molecules? And why are physicists so reluctant to try to fabricate new materials with interesting properties in the way that chemists do? Why, also, the total lack of summer schools in France on condensed media? On the research side, although the committee has clearly set out to forge something resembling a national science policy for condensed media the impression remains that the drive towards investigating new materials—amorphous solids and liquids, for instance—and the growing predominance of a handful of powerful techniques have established a momentum of their own which the committee has no wish to more than trim.

The committee suggests that a national laboratory be set up to tackle the vital problems of sample preparation including the growth of highly pure crystals, thin films and materials of special structure. This would be comprised of high calibre physicists and engineers of the CNRS and would complement the simpler facilities which should be provided in every major physics department. With regard to surface physics, the committee warns of the danger of rushing to apply new phenomena in devices before fundamental research on a wider range of materials has been tried.

The terms of reference of the committee, set up by the Délégation Générale à la Recherche Scientifique et Technique in conjunction with the French Science Research Council, the CNRS, were inspired by the report of a government scientific committee in 1968 which prescribed the need for tighter coordination and firmer prediction of scientific policy. One area which the committee believes French physicists are well poised to exploit is non-linear optics, which has blossomed forth recently as a technique for studying relaxation processes. It offers significant improvement over traditional shock tube methods and ultrasonics and has great potential for exploring phonon coupling, very fast chemical reactions and phase transitions. The development of the technique has been hampered by the limitations on laser wavelengths, and the committee underlines the urgency of research into low wavelength lasers and laser systems for producing extra short pulses.

Two new spectroscopes using synchrotron radiation and photoemitted electrons are singled out for special mention, primarily for studying electron states in solids. In its attitude to research on liquids, the committee echoes much of what was said in a recent report of the British Science Research Council on amorphous materials (see *Nature*, **227**, 108; 1970), which placed strong emphasis on neutron and X-ray studies and on computer simulation (molecular dynamics). Professor Friedel's committee looks forward, however, to the completion of the joint French–German high flux beam reactor in July 1971 at the Institut Laue–Langevin in Grenoble, and highlights some of the experiments on macromolecules, critical phenomena and magnetic scattering—to name but a few—which will be competing for the 10^{15} slow neutrons cm^{-2} s^{-1} from the reactor. Twenty experimental areas are being prepared for measurements in solid state physics and another fifteen will be installed later on. The reactor is also being equipped with a hot source to increase by a factor of 10 the flux of neutrons at 0·5 eV. The committee issues a reminder that the novelty of a high flux neutron beam should not be allowed to dull the complementary part played by other techniques in the study of condensed media.

Work on high magnetic fields seems to be flourishing in France. The next two years will see the installation of superconducting magnets for fields up to 150,000 Oersteds and the extension of pulse field techniques to reach 500,000 Oersteds for more than 0·1 s. A wide range of applications is envisaged including detailed studies of magnetic transitions and the effects on magnets of high pressures up to 7·10 torr. The scope for studying different forms of phase transitions is reiterated frequently throughout the report, but the committee fights shy of suggesting any possible redeployment of facilities to this end.



SPACE RESEARCH

After Luna 16

from our Soviet Correspondent

THE return to Earth of Luna 16 with its cargo of Moon rocks is an undoubted triumph for Soviet space exploration, but it also raises once again the thorny question of manned versus unmanned projects in Soviet space research.

Although it seems certain that the planning of a manned mission to the Moon once took priority in the Soviet space programme, the loss of the captain designate (Gagarin) and chief training officer (Belyaev) caused some considerable setbacks and consequent rethinking. According to Academician B. N. Petrov (*Pravda*, September 24, 1970), the Moon programme is at present conceived of in two stages: (1) "preliminary (reconnaisance) investigations with the aid of automatic spacecraft; (2) subsequent multilateral

Artist's impression of Lunar 16 on the Moon. Drawn by A. Sokolov.

systematic research and investigation by means of both automatic and piloted craft for the wider use of the achievements obtained for the aims of science and the national economy".

At present, Soviet space flight is still in the early reconnaisance stage. Petrov pointed out that manned Moon-flights and interplanetary missions would not only involve considerable additional expense, but they also present a risk to human life which is unjustifiably great at the present time. Petrov gives no absolute costs, but he does claim that a manned mission would cost more than twenty times as much.

For the time being, therefore, Soviet long-range space flight seems likely to remain automatically based. After the acquisition and safe return to Earth of the lunar samples by Luna 16, what other robot successes may be expected in the future ? The academicians who have commented on the current exploit are, as usual, not eager to commit themselves. B. V. Raushenbakh, a corresponding member of the Academy of Sciences of the Soviet Union and an expert in automatic control, suggests in a *Pravda* interview, however, that one of the advantages of an automatic space-craft is that it can operate in conditions which would be highly hazardous for a human crew, notably in radiation belts. This might be taken to mean that a future project of equal scientific if less publicity value will be a prolonged investigation of the Earth's radiation belts. A long-term mapping of the activity of the radiation belts would, of course, be a reasonable preliminary to the construction of a manned earth orbital space station, as a base for manned Moon missions.

MOLECULAR BIOLOGY

No Home for EMBO Laboratory

A SITE in Munich for the International Laboratory of the European Molecular Biology Organization has just been offered by West Germany to a working group of the European Conference on Molecular Biology (the association of fourteen European states which provides the funds to support EMBO) which met earlier this week at the Hague to consider what steps the ECMB should now take in establishing the proposed EMBO laboratory.

The second plenary session of the ECMB itself will take place at the end of next month to consider the proposal of the working group that four further working parties should be set up to consider in detail the budget of the EMBO laboratory, the way in which it should be organized, the legal framework within which it should operate, and offers of four sites where it could be built.

Although tentative sites for the laboratory were offered by France, Austria and Italy some time ago, and EMBO itself proposed that the most convenient site would be Geneva (where CERN is already located), the offer of the site at Munich is the first firm proposal and it seems quite likely that the ECMB will decide to accept it. One of the attractions of this offer is that temporary accommodation could be provided in new buildings which are presently under construction at the site; this would enable the laboratory to start work before its own buildings could be completed.

If the ECMB agrees to the proposal of its working group, the four working parties could start work at the end of November and report back to an extraordinary session of the ECMB in April. This would mean that work could start next year on building the laboratory and the original aim of having it in operation by 1973 and fully functional by 1975 may still be met.

EMPLOYMENT

Biologists leave the Laboratory

BIOLOGY graduates are likely to have to broaden their horizons when seeking employment in the future. There were signs at a meeting of members of the Institute of Biology in London on September 25 that biology and allied disciplines will not be able to absorb all the biologists who want to stay in research. Too many biologists, it seems, have been reluctant to drop the study of plants and animals and pursue careers in banking, operational research, the civil service and so on.

Professor L. Broadbent (University of Bath) said that although there are more jobs than graduates in some branches of biology, the percentage of biologists unemployed six months after graduation has been increasing recently, according to figures from the University Grants Commission. Although unemployment is not a big problem for biochemists and microbiologists, 6·4 per cent of general biologists, botanists, zoologists and some other specialists were unemployed in 1968, compared with 3·4 per cent for all scientists.

The general pattern of employment among biologists, he said, was 36 per cent in school teaching, 7 per cent in further education, 22 per cent in universities, 22 per cent in state aided research and 13 per cent in industry. One of the best professions for a young biologist to enter is horticulture said Professor Broadbent; there are some very good jobs for well trained people. But biochemistry still takes the most biologists—18–26 per cent of them work in this discipline.

More biologists are taking the plunge into industry and commerce because, said Professor P. N. Campbell (University of Leeds), it is becoming increasingly difficult for those with a degree less than a good II(i) to find research posts. He was pleased to note that some really good students are now taking up school teaching. Professor Campbell also thought that the increase in medical education now in progress would absorb a good many biologists.

Professor G. Belyavin (University College Hospital, London) predicted that biologists will find a warmer welcome in medical research as the need for fundamental investigators increases. He did not think that prejudice against non-medically qualified people in medical laboratories would ever quite disappear, but the barriers were coming down. Diagnostic techniques are being developed by biochemists, microbiologists, cytologists and so on, and Professor Belyavin saw the demand for their services increasing in the future.

The problem raised for the educationalists is, of course, what to teach biologists to equip them for the roles they will have to play in the future. One step towards the general education of biologists is the undergraduate course in human biology, which is about to begin in Oxford. One of its founders, Professor J. W. S. Pringle, describing the broad scope of biology, anthropology and sociology that it contains, said that, when asked what jobs his graduates will do, he replies that he hopes they will become prime ministers.

NATURE VOL. 228 OCTOBER 3 1970

NEW WORLD

Scranton Commission Prescribes

by our Washington Correspondent

THE President's Commission on Campus Unrest has made a visibly sincere effort to understand what students are bothered by and to prescribe against the causes of violent dissent at the universities. In a report of some 350 pages made public this week the commission criticizes the role of students, faculty and administration as well as the part played by the Federal government and the police in response to university unrest. A major theme of the report is that universities and faculty members should make substantial accommodations towards student demands for better teaching and more responsive administration; at the same time the commission calls for universities to adopt a firmer and more clearly defined stance towards disruptions.

The commission, chaired by the former governor of Pennsylvania, Mr William W. Scranton, was appointed by President Nixon in June in the wake of the nationwide riots that followed the invasion of Cambodia and the shooting of the four students at Kent State University. In the past few weeks there have been several attempts to shoot the commission's findings down before they were even launched, based on the expectation that they would blame the President's Cambodian policy for the rioting. Although the commission could not ignore the part played by the invasion, its analysis of the problem has gone far deeper than the immediate causes of the unrest. But the attempt, such as it is, to spare Mr Nixon's political profile may not be much help. With an eye on the approaching Congressional elections most politicians see more sense in excoriating student unrest than in trying to understand it.

The commission prefaces the list of its recommendations with the observation that "the roots of student activism lie in unresolved conflicts in our national life, but the many defects of the universities have also fuelled campus unrest". Its recommendations, many of them couched in general rather than specific terms, are addressed to the President, to the government, to those charged with enforcement of the law, and to universities and students (see page 9). Both the President and government officials are urged to avoid divisive rhetoric. The President is reminded of the importance of ending the Vietnam war. The government should increase its support of education, particularly its financial aid to Black colleges and universities. Officers sent on to the campus should be trained how to control disorders without resorting to excessive measures. Universities should strengthen their disciplinary procedure and acknowledge with new courses and organization the changes imposed by the expansion of higher education and the emergence of the "new youth culture". Universities and faculty members should reduce their outside commitments, since these have reached a volume that seems to compromise the devotion to research and teaching. Finally, the students should learn to appreciate the necessity of tolerance and allow hearing to views with which they disagree.

In its chapter on university reform the commission says that in the past few decades there has been a serious erosion in the universities' sense of mission and a failure to give priority to their central purposes. The failure, the commission says, has arisen in four major ways. First, academic freedom has been threatened by increasing political pressure both from within the university and outside it. Second, teaching and research have been compromised by devoting vital resources to peripheral activities. Third, too few new and academically respectable programmes have been developed because the pace of educational change has been too fast at some universities and too slow at others. Finally, the traditional assumptions about how a university should operate have been invalidated by the erosion of the "minimal but essential sense of community once shared by most faculty, students and administrators".

Turning to the political pressures on the university, the commission notes that universities may have to act politically when the interests of higher education are at stake. But such institutional positions compromise the academic ideal of neutrality and should be taken only as a last resort and when there is clear evidence concerning the direct effects of government policy on higher education. Political involvement of individual members of universities is, of course, quite another matter.

The commission observes that services performed by universities for other organizations have become a major source of income that on some campuses now provides the bulk of the operating budget. The commission recommends that these outside service commitments be reduced; in particular, although much of the research undertaken for the Department of Defense has academic merit, universities should refuse to undertake any classified research and should "terminate existing classified projects unless it is clear that the undesirable results of undertaking such a project are outweighed by compelling advantages". The commission notes ironically that student protests against defence research have increased as the quantity of research has decreased. Nevertheless, the requirement appended to the Military Authorization Act of 1970 that all defense research projects bear a direct and apparent relationship to a specific military function has placed university scientists in the embarrassing position where, having certified for the benefit of Congress that their research has a direct military application, they must then contend with student accusations that they are "working for the war machine". Noting that the universities cannot avoid sharing in the national defence research effort, the commission says it "does not advocate termination of either defence-funded or government-funded research in general, but we urge that such research be planned so as to interfere as little as possible with the normal function of the schools in which it takes place".

Not only the university as an institution but its individual members should reconsider their services to outsiders. The "entrepreneurial professor" who is so heavily engaged in outside research that he has become

almost inaccessible to his students is compromised in their eyes because of his "attachment to rewards more material than the discovery of truth". The commission recommends that universities should establish general guidelines governing the acceptance of outside research both at an institutional level and by individual faculty members. The guidelines should restrict any outside service activities that drain energies away from research and teaching, but they should be sensitive both to the individual rights of faculty members and to the differences between teachers in various disciplines. Committees of faculty members and administrators should develop and enforce the guidelines. The general criterion should be not that "every full professor is entitled to his sideshow" but whether the sideshow will contribute to teaching or to knowledge.

The commission finds some justice in student complaints at the quality of teaching, generally blamed on excessive outside faculty commitments, university reward systems biased in favour of research and publication and faculty indifference to improving the teaching system. As one way of improving the quality of teaching, the commission urges that the practice of tenure be reconsidered. "Tenure has strong justifications because of its role in protecting academic freedom of senior faculty members. But it can also protect practices that detract from the institution's primary functions, that are unjust to students, and that grant faculty members a freedom from accountability that would be unacceptable for any other profession."

Another object of the commission's criticism is that practice of relying heavily on graduate students to do much of the teaching. Graduate students are "necessarily inexperienced, often distracted by the demands of their own degree programme . . . and in some cases deeply disillusioned". The commission says it would strongly recommend abolishing graduate teaching assistantships altogether were it not for the fact that the universities cannot at present afford to do so.

Major Recommendations

"We recommend that the President seek to convince public officials and protesters alike that diversive and insulting rhetoric is dangerous. In the current political campaign and throughout the years ahead, the President should insist that no one play irresponsible politics with the issue of 'campus unrest'.

"We recommend that the President take the lead in explaining to the American people the underlying causes of campus unrest and the urgency of our present situation. We recommend that he articulate and emphasize those values all Americans hold in common.

"To this end, nothing is more important than an end to the war in Indochina. Disaffected students see the war as a symbol of moral crisis in the nation which, in their eyes, deprives even law of its legitimacy. Their dramatic reaction to the Cambodian invasion was a measure of the intensity of their moral recoil.

"We recommend that the President take steps to assure that he be continuously informed of the views of students and Blacks, important constituencies in this nation.

"We strongly urge public officials at all levels of government to recognize that their public statements can either heal or divide. Harsh and bitter rhetoric can set citizen against citizen, exacerbate tension and encourage violence.

"We recommend that the federal government review all its current policies affecting students and universities to assure that neither the policies nor administration of them threatens the independence or quality of American higher education. At the same time government should increase its financial support of higher education.

"We recommend greatly increased financial aid for Black colleges and universities. All agencies of government that support such institutions should massively increase their grants to enable these colleges to overcome past shortcomings.

"Bombing and arson pose an increasing threat to lives and property on campus. We urge prompt enactment of strict controls over the sale, transfer, and possession of explosive materials.

"Too frequently, local police forces have been undermanned, improperly equipped, poorly trained, and unprepared for campus disturbances. We therefore urge police forces, especially those in smaller communities, to improve their capacity to respond to civil disorders.

"The university should promulgate a code making clear the limits of permissible conduct and announce in advance what measures it is willing to employ in response to impermissible conduct. It should strengthen its disciplinary process. It should assess the capabilities of its security force and determine what role, if any, that force should play in responding to disorder.

"When criminal violence occurs on the campus, university officials should promptly call for assistance of law enforcement agencies.

"When faced with disruptive but non-violent conduct, the university should be prepared to respond initially with internal measures. It must clearly understand the options available to it and be prepared to move from one to another if it is reasonably obvious that an earlier tactic has failed.

"Faculty members who engage in or lead disruptive conduct have no place in the university community.

"The university, and particularly the faculty, must recognize that the expansion of higher education and the emergence of the new youth centre have changed the makeup and concerns of today's student population. The university should adapt itself to these new conditions. We urge that the university makes its teaching programmes, degree structure, and transfer and leave policies more flexible and more varied in order to enhance the quality and voluntariness of university study.

"We call upon all members of the university to reaffirm that the proper functions of the university are teaching and learning, research and scholarship. An academic community best serves itself, the country, and every principle to which it is devoted by concentrating on these tasks.

"One of the most valid criticisms of many universities is that their faculties have become so involved in outside research that their commitment to teaching seems compromised. We urge universities and faculty members to reduce their outside service commitments. We recognize that alternative sources of university funding will have to be developed to take the place of the money attached to these outside commitments.

"Large universities should take steps to decentralize or reorganize to make possible a more human scale.

"University governance systems should be reformed to increase participation of students and faculty in the formulation of university policies that affect them. But universities cannot be run on a one man, one vote basis with participation of all members on all issues.

"Students must protect the right of all speakers to be heard even when they disagree with the point of view expressed. Heckling speakers is not only bad manners but is inimical to all the values that a university stands for.

"Students must face the fact that giving moral support to those who are planning violent action is morally despicable."

APOLLO CUTBACK

Has NASA Finished with the Moon?

by our Astronomy Correspondent

WITH Luna 16 back on Soviet soil, carrying an unspecified amount of lunar material, it is conceivable that the Soviet Union could be taking the initiative in the exploration of the Moon within a few years. Luna 16 has come at an awkward time for NASA which has just turned its back on the Moon; planetary scientists in the west are still licking their wounds after the loss of a further two Apollo missions, cancelled apparently so as to keep within the budget for the current financial year and to have something in hand for possible post-Apollo programmes. Only four more flights to the Moon are now planned, Apollos 14, 16, 17 and 18. NASA's decision flies in the face of both the Space Science Board of the National Academy of Sciences and NASA's own Lunar and Planetary Missions Board. On August 13 the two boards were asked by the then administrator of NASA, Dr Thomas O. Paine, to consider the scientific consequences of either continuing with the Apollo programme as then planned or of cancelling two of the missions. "Any reduction in the number of missions will seriously threaten the ability of the total Apollo programme to answer first-order scientific questions", was the boards' answer in their joint report signed by Professor Charles H. Townes of the University of California (Berkeley), chairman of the Space Science Board, and Dr John W. Findlay, assistant director of the National Radio Astronomy Observatory and chairman of the Lunar and Planetary Missions Board. "We are on the very beginning of a learning curve, and it is clear that the loss of one mission will have much greater than a proportional effect on the instrumented experiments and, more critically, on the design and execution of the geology experiments involving the astronauts". Possibly with an eye to the prevailing lack of public enchantment with space science, the report ends by saying that "the consequences of such failure [to answer first order questions about the Moon] for the future of the agency and, we believe, for large-scale science in this country, are incalculable".

By rejecting cancellation, the two boards agree with everybody else that the elementary questions about the origin of the Moon will not be solved until samples have been collected from a variety of sites. Although the capability of the new series of Soviet Moon probes which seems to have begun with the unsuccessful Luna 15 nearly fifteen months ago is an unknown quantity, they, rather than NASA, could soon be providing the material from the desirable diversity of sites. How successful the Luna series will be at this job depends chiefly on whether the ascent stage brings back egg-cupfuls of dust or intact pieces of rock, which for the moment seem to have more to say about the history of the Moon, and whether it gropes for samples like a blind man or is fitted with television so as to pick and choose. Moscow has let slip that a drill penetrated fourteen inches below the surface, so Luna 16 would seem to have some sophistication.

While Luna 16 is laying the foundations for a possible swing towards lunar science in the Soviet Union, in the West people are trying to come to terms with the latest cancellations in the Apollo programme. At best Houston will now receive samples from only six sites, including the two mare sites already visited. After June 1972 no more Apollo flights to the Moon are planned. Although NASA officials must be glad that the cancellations which have been in the air for some time, to the detriment of NASA's planning, have at last been agreed on, the onus is now on the scientists to pick the most profitable sites. Fra Mauro has already been chosen for Apollo 14 in January, of course. The final three missions will be in July 1971, January 1972 and June 1972, and the landing sites in the running are the Marius Hills, Copernicus, Davy, Hadley Rille and Descartes. It is thus conceivable that there will be no samples from a rille, or from the central peaks of Copernicus which are believed to have originated deep within the Moon.

Although the Space Science Board and the Lunar and Planetary Missions Board grudgingly admit in their report that the loss of Apollo 15 from the programme would be bearable, they refuse to countenance the loss of Apollo 19. Apollo 15 was to be the last mission before a factor of two jump in the capabilities of the Moon flights, to be brought about by improvements in the space suits and a doubling of the scientific payload that can be landed on the surface, but chiefly by the inclusion of a lunar vehicle which will be carried from Apollo 16 on. But the loss of Apollo 15 is regarded as serious because it means one less site to be sampled, one less scientific package left on the Moon, and one less opportunity for gaining experience before the scientific exploration begins in earnest with Apollo 16. But in their report to Dr Paine the boards saw the cancellation of Apollo 19 as little short of disastrous because it will reduce by at least 20 per cent the total time spent on lunar surface activity during all the Apollo flights, and the total length of lunar traverses will be reduced by at least 25 per cent. It will now be up to NASA's scientists to make the most of the four flights left by choosing the best of the experiments that would have been carried on the original six flights, and by trying to accomplish next year and in 1972 the experiments that would have taken until the last two Apollo flights that were scheduled for 1974 to prepare.

By cancelling Apollos 15 and 19, renumbering the remaining missions from 15 to 18, Dr Paine says the Apollo budget for 1971 will be reduced by $42·1 million, which will go a long way to making up the deficit of $64 million between what NASA asked for and what they will almost certainly receive. Further appreciable savings will come by deferring the construction of new laboratories and by savings on the tracking and data acquisition side related to the cutback in the Apollo programme. But the cancellations also mean that NASA will have two Saturn 5 boosters in hand which could be mothballed for possibly as long as ten years. Dr Paine sees them as a national resource which can be used in the Skylab project, for tests of the Nerva nuclear rocket, or for manned or unmanned launches to a geostationary orbit. He also says that the cancellations will make things easier in 1972, 1973 and 1974 when money will be freed for future programmes such as the space shuttle and the space station. The same time interval should see several important unmanned projects reaching important stages, the high energy astronomical observatory and the grand tour flights, for example.

Once the Skylab programme is over in mid-1973,

there are no further plans for manned spaceflight until the first tests of the space shuttle, at present little more than a gleam in the eye. The optimists say that could be in 1976 or 1977. For the planetary scientists in the West, the cancellations have come just when appetites have been stimulated by the first two collections of samples. According to Dr Findlay "all scientists would regard the chief loss is the danger, the probability in fact, that we will not get our first order scientific answers about the Moon from the Apollo programme".

It is implicit in this that the elimination of Apollos 15 and 19 will give NASA more elbow room when the Skylab programme is under way in November 1972. It seems a poor swap, however—people are hard-pressed to give a scientific justification for the Skylab programme that will compare with the value of a visit to a lunar rille, for example. NASA's decision hurts because it has brought home to people that science has never been high on the agenda for manned space flight. Following the ructions during Apollo 11 when the lunar scientists complained of being too far from the action, science has had a hey-day in the Apollo programme. The traverses that the Apollo 13 astronauts would have followed were carefully thought out, and people have had a merry time thinking up experiments that could be carried on later flights. Now after little more than a year the real state of play has been brought home. "There is almost nothing in manned space flight I would justify on the basis of science. Science is an adjunct to manned flight", the acting administrator of NASA, George Low, is reported as saying. To be fair, however, NASA's continual searching for new fields to conquer which appears to be behind the Skylab project and the shuttle is as much as anything to appease a Congress that is unenamoured of space activities.

DEFENCE

Arms Race Soldiers On

by our Washington Correspondent

AMERICAN spy satellites orbiting over the Soviet Union have spotted 18 new sites at which construction of SS-9 missile silos has begun. Since the giant missile is usually deployed in groups of six, this raises from 220 to more than 300 the number of SS-9s being deployed by the Soviet Union, Dr John S. Foster, director of Defense Research and Engineering, announced last week. The new silos, first detected in July, represent a renewal of the Soviet SS-9 programme which, whether coincidentally or otherwise, has been kept on ice since the Strategic Arms Limitation Talks (SALT) began in November last year.

The SS-9 missile is a large launching vehicle carrying either a single warhead of 25 megatons or three warheads each of five megatons. Its deployment is alarming to the United States since it is regarded as capable of destroying Minuteman missiles in their hardened silos and as such is a first strike weapon. (The smaller but more accurate multiple warheads which the United States will begin deploying in its Minuteman III missiles are, like the SS-9, silo-busting weapons). Dr Foster's announcement about the Soviet resumption of the SS-9 programme was made, as it happened, a day before representatives of the Senate and the House of Representatives met to discuss the two chambers' different versions of the defence procurement authorization bill which includes the funding for the anti-ballistic missile (ABM) or Safeguard System. Despite Dr Foster's announcement the Senate's position on Safeguard, which allows work on ABM systems to begin at only two more sites in addition to the present two, prevailed over the House's version which would have allowed the Administration's request to expand the ABM system to six more sites, making eight in all. This proposal would have provided a blanket defence of the United States against a "light" missile attack, such as the Chinese may soon be in a position to mount. In the Senate the Chinese defence aspects of Safeguard were killed off at the committee stage before the bill had reached the floor of the House.

In the Senate debate (see *Nature*, **227**, 770; 1970) the spokesmen for the Administration made much of the argument that expansion of the Safeguard system to two additional sites would serve as a bargaining counter in the SALT talks. The Soviet redeployment of the SS-9 is also seen as an attempt to gain more leverage at the SALT talks. Last week Ambassador Gerard Smith, the chief US negotiator, was briefing the House subcommittee on national security policy on the progress of the SALT talks and the prospects of trading away the respective bargaining counters. Meanwhile, the Air Force is requesting approval for a $1,000 million programme to harden its 1,054 Minuteman sites, presumably as an insurance policy against the ABM system either not working or being traded off.

ENVIRONMENT

Senate wins Clean Car Race

by our Washington Correspondent

AMERICANS may be able to breathe again if a bill passed by a 73 to nil vote in the Senate last week becomes law. In a list of measures far more stringent than those called for by President Nixon, the Senate has set out to bring the major sources of air pollution under control by 1975. The most controversial demand is that, beginning in 1975, all new cars must meet the exhaust emission standards which the Administration had proposed should be met only by 1980.

The Senate bill also requires certain industries to install in all new factories and extensions to old ones the most advanced technology available for reducing air pollutants. An important general measure is the provision for national air quality standards setting levels protective of health for the major known air pollutants. These are particulates, sulphur dioxides, hydrocarbons, carbon monoxide, photochemical oxidants and nitrogen oxides, which together account for more than 98 per cent by weight of all air pollution.

Passage of the bill is a triumph for Senator Edmund S. Muskie, chairman of the subcommittee on air and water pollution, but the extent of his final victory will depend on what compromise is reached with the House of Representatives which earlier this year passed as mild a bill as President Nixon had asked for. The present legislation is the third attempt to make air polluters desist since the Clean Air Act of 1963, but it departs from the philosophy of its predecessors by setting standards and letting industry develop the technology to meet them. The previous attitude has

been to see what industry claims is attainable with the technology at hand and making that the basis of legislation, whilst allowing pollution that it is not economically feasible to control to continue unabated.

The policy of putting the horse before the cart has drawn the predictable reaction from the car industry. "General Motors does not at this time know how to get production vehicles down to the emission levels that your bill would require for 1975 models", the president of General Motors, Mr E. N. Cole, wrote in a letter to Senator Muskie; "accomplishment of these goals, as far as we now know, simply is not technologically possible within the time frame required". The refrain was echoed by Mr Lee Iacocca, president of Ford's North American automotive operations, who said the requirement to reduce vehicle emissions by 90 per cent "could prevent production of cars after January 1, 1975".

Table 1. AUTOMOBILE EMISSIONS PERMITTED BY PROPOSED FEDERAL STANDARDS AND BY THE SENATE BILL (IN GRAMS PER MILE)

	Hydrocarbons, new test	Carbon monoxide, new test	Nitric oxides, old test	Particulate matter, old test
Uncontrolled	14·6	116·3	4·0	0·4
1970 standard	2·9	37·0	—	—
Proposed 1975 standard	0·5	11·0	0·9	0·1
Proposed 1980 standard	0·25	4·7	0·4	0·03
Bill language (90 per cent reduction of 1970 or uncontrolled)	0·29	3·7	0·4	0·04

The princes of Detroit might have won more conviction for the prophecies of their own demise had it not been for the annual Clean Air Car Race, run between the Massachusetts and California Institutes of Technology, in which student engineers are scored for the cleanliness as well as performance of their vehicles. Results of this year's contest, announced only a few days before the Senate debate, showed that the Federal emission standards proposed for 1980 (and by Senator Muskie's bill for 1975; see Table 1) were well within the grasp of the college teams, even though no single vehicle met the levels set for all three classes of emission (hydrocarbons, carbon monoxide and oxides of nitrogen). The winner of the race, a modified Ford Capri, entered by Wayne State University, emitted 0·19 grams per mile of hydrocarbons and 1·48 of carbon monoxide, both of which are better than the standards set by the Senate bill, and its emission of oxides of nitrogen was very close to standard.

Where Wayne State University had led, could not Ford and General Motors follow? Their wellwishers on the floor of the Senate explained that there was all the difference in the world between the Wayne State entry and a vehicle suitable for mass production. For one thing, the student car had four converters using a prohibitively expensive platinum catalyst; for another, the manufacturers are being required by the bill to guarantee their vehicles' cleanliness for 50,000 miles. The Senate on this occasion refused to be blinded with technology. Mr Muskie pointed out that the deadline in his committee's bill allows the car manufacturers two years to do the necessary research and development and another two years in which to apply that technology to the mass production of automobiles. If the technology to get to the Moon could be developed in ten years, Mr Muskie implied, the requirement to reduce car exhaust emissions by 90 per cent in four years was asking for rather less.

Table 2. EMISSION OF AIR POLLUTANTS IN THE UNITED STATES, 1968 (MILLIONS OF TONS)

Source	Carbon monoxide	Particulates	Sulphur oxides	Hydrocarbons	Nitrogen oxides	Total
Transportation	63·8	1·2	0·8	16·6	8·1	90·5
Fuel combustion in stationary sources	1·9	8·9	24·4	0·7	10·0	45·9
Industrial processes	9·7	7·5	7·3	4·6	0·2	29·3
Solid waste disposal	7·8	1·1	0·1	1·6	0·6	11·2
Miscellaneous	16·9	9·6	0·6	8·5	1·7	37·3
Total	100·1	28·3	33·2	32·0	20·6	214·2

(From the report of the Council on Environmental Quality.)

The most telling argument against the manufacturers is that cars and other vehicles are responsible for nearly half the total air pollution, accounting for some 42 per cent of the estimated 214 million tons of pollutants released into the air in the United States in 1968 (see Table 2). "Detroit," Senator Muskie remarked, "has told the nation that Americans cannot live without the automobile. This legislation would tell Detroit that if that is the case, they must make an automobile with which Americans can live."

BIOLOGY

Coping with Acanthaster

by our Washington Correspondent

FUNDS totalling $4.5 million have been voted by Congress for a five year programme to control the crown-of-thorns starfish, *Acanthaster planci*, whose ravages of Pacific coral reefs have reached epidemic proportions in the last few years. The programme, which is to be administered by the Department of the Interior and the Smithsonian Institution, calls for research into the ecology of the starfish, together with the development of better methods of control.

The immediate beneficiaries of the programme will be the Pacific territories of the United States such as Guam and Hawaii. Since 1967 more than 23 miles of the coral reefs round Guam have been almost completely destroyed by the starfish. In Hawaii a serious infestation has been found off the coast of Molokai island. Elsewhere in the Pacific the Great Barrier Reef is the best known casualty, having been denuded of 100 square miles between 1964 and 1966. (A recent survey of the Reef, however, suggests that regeneration of the coral may not be so protracted a process as is supposed (see *Nature*, **227**, 5; 1970).)

The bill authorizing the *Acanthaster* research programme passed the Senate in April. In last week's debate in the House, Representative Mink of Hawaii suggested that the funds should be used to set up a Coral Reef Institute which, she thought, should be situated with the University of Hawaii. To begin with, the Institute would devote its energies to the *Acanthaster* problem but, with that solved, it would turn to other questions of coral ecology such as the effects of algae and fish farms being established in the Philippines.

The Smithsonian Institution will use its share of the funds to study the general biology of the crown-of-thorns starfish whilst the Department of the Interior will study control methods. So far the most effective method of halting the plague is for divers to inject starfish individually with formalin or ammonium hydroxide.

NEWS AND VIEWS

Is Your Jamboree Necessary?

NOBODY returning to his laboratory in late September after the round of conferences, commissions, round-tables and workshops has much time to sit down and assess the worth of all this summer activity, which, in any case, continues through the other seasons of the year. Many fatigued travellers may have begun to doubt the value of their conference or colloquium, yet new committees are already well advanced with preparations for 1971 and there are even preliminary announcements for 1972. Is it midsummer madness or does the scientific community gain from the scientific and social fellowship? And which aspect is the more important?

Meetings—at any time of the year—clearly fulfil an essential function in a system in which the written word is at once indispensable and yet ineffectual. The story is better told by word of mouth in some darkened baroque hall in central Europe or over a beer on the beach at Cold Spring Harbor than in an unrelieved text which omits the snags and veils the humanity of research. Even props such as slides can detract from the message and it was said at the recent biochemical meeting in Interlaken (*Nature*, **227**, 1195; 1970) that one speaker who lost his slides performed almost more effectively with some which were hand-drawn at the last moment. But is a big meeting the right place for personal contact? Is there a defence for the jamboree? It is, of course, part of the history of science that much is lost when a larger discipline splinters into specialities, but communication is more efficient at meetings of less than 500 than at those in excess of 5,000. There is the extra difficulty of managing a large audience and finding an adequate auditorium, so the problem is to decide whether to bring together the 5,000 and then split them into ten sessions or to sunder the disciplines into ten specialities and let them go their several ways. Given a superb organization such as that at the federation meeting at Atlantic City, the first method can work efficiently. But if the chairman lags or the transit bus is late, the ranks may just as well be split. The onus is also on the organizers, but as at the International Astronomical Union meeting (*Nature*, **227**, 991; 1970), participants should not be lulled into thinking that the proceedings will always be smoothly conducted.

One saving grace of the jamboree is, of course, the chance it gives for cross-fertilization of ideas. Another is that younger investigators do at least have a sight of the veterans. So often, however, the veterans have themselves just come from a more intimate and exciting gathering. Their latest discoveries are presented somewhat casually for this larger throng, and those on the periphery get a false impression of the state of the art and the co-veterans complain that the meeting had nothing new to offer. Again it is for the conveners to apply the more rigorous criteria necessary for the selection of speakers and contributions. No one would wish them to turn down a brilliant speaker because he is saying no more than he had said many times before, and it would be unjust to turn away a small jewel of discovery just because it is known that the speaker is inaudible and inarticulate. But surely there is some way of avoiding "poster sessions" and papers "read by title only".

From the editorial point of view, there is the question of the timing of publication of the reported findings. In a bygone age, investigators more often subjected their reports to public scrutiny before submitting them to a journal, but now it is common simultaneously to compose an abstract for the conference secretary and a manuscript for a journal. The consequence of this in the case of the recent International Congress of Biochemistry was that a dozen or more contributions corresponded to articles just about to appear in *Nature*, and many others were in the press elsewhere. The procedure is not formally incorrect, but most editors feel safer with work submitted after a meeting and revised in the light of comment, and most organizers anxious to ensure a high level of novelty at their meeting will be happier if more contributions have an air of freshness about them.

There are signs that the value of big meetings is being seriously debated, but so far there is little indication of their universal abandonment. In Interlaken, there were some misgivings about the future of the International Congress of Biochemistry, but it seems that the triennial meetings will continue, with Sweden as the host in 1973. The International Association of Microbiology has decided to discontinue—or to fragment—its mammoth conferences but, on the other hand, an International Society of Immunology has been formed which is looking forward to its first meeting in Washington in 1971. It is up to each society to decide in such matters, preferably after ballot or debate, but if individuals have no inclination to voice an opinion on the best means of communicating with colleagues it is likely that the initiative will be taken by those who ultimately have the greatest say and also the greatest self-interest in the business—the grant-giving authorities.

TUMOUR VIRUSES

Dissecting Virions

from our Cell Biology Correspondent

MOLECULAR biologists attracted to the RNA tumour viruses by the recent discoveries of Temin and Mizutani and Baltimore only to find that this particular field is already overcrowded might consider tackling the more mundane job of analysing the composition of the RNA tumour virus virion. For surprisingly little is known about the collection of RNAs, proteins, lipids and carbohydrates which comprise these viruses.

All the RNA tumour viruses contain an RNA molecule which sediments at about 65S and a collection of much smaller RNAs which sediment at about 4S in sucrose gradients. The 65S RNA is presumed to contain the genetic information of the virus, but it is not known whether the 65S RNA is exclusively viral or contains a mixture of viral and cellular RNA. The structure of the 65S RNA has not been determined unambiguously either. Several lines of evidence suggest that it is made up of three or perhaps four smaller molecules held together by weak bonds, but the possibility that the 65S RNA is a single polynucleotide chain capable of extreme changes in configuration has not been eliminated conclusively.

The 4S RNA in the virions of the RNA tumour viruses has been more fully characterized, and at least some of this RNA seems to be transfer RNA. Two years ago Travnicek reported that unpurified 4S RNA from avian myeloblastosis virus (AMV) particles accepts amino-acids. Now Erikson and Erikson (*J. Mol. Biol.*, **52**, 387; 1970) report that the 4S RNA of this virus includes valine, proline, methionine, glycine, aspartic acid and arginine transfer RNAs. The amino-acid accepting activity of the viral 4S RNA for five other amino-acids was either very much less than that of cellular 4S RNA or undetectable. Apparently each AMV particle contains about 200 tRNA molecules per molecule of 65S RNA. Either during virus maturation the transfer RNAs are selectively incorporated into the virions, or all the tRNAs of the cell are incorporated, but some are selectively inactivated while in the virion or during extraction from it.

The proteins in these viruses occur in the viral envelope and associated with the RNA in the internal nucleoid; those proteins in the nucleoid are believed to give rise to the group specific antigenicity which differentiates the viruses in one group, for example the avian or murine viruses, from those in all other groups. The proteins in the envelope, on the other hand, seem to give rise to the subgroup antigenicity which distinguishes different viruses within a group, and has a role in restricting the host range of a particular virus. Duesberg, Martin and Vogt (*Virology*, **41**, 631; 1970) have recently isolated two glycoproteins containing glucosamine, galactose and fucose from several strains of Rous sarcoma virus and Rauscher murine leukaemia virus. These two proteins which constitute about 10–20 per cent of the total protein in the virions have molecular weights of about 90,000 to 105,000 and about 37,000. The glycoproteins from different strains of Rous sarcoma virus have different electrophoretic mobilities and inhibit the action of neutralizing subgroup specific antisera. It seems therefore that these glycoproteins are part of or identical with the subgroup antigens. Duesberg *et al.* have also detected three proteins common to the Rous sarcoma viruses they examined which are not glycosylated and are probably responsible for the group specific antigenicity. Which, if any, of these proteins correspond to the enzymes that Temin and his followers are discovering remains to be seen.

PROTEINS

Endless Enzymes

from our Molecular Biology Correspondent

THE concentration-dependent association of enzymes into long filamentous formations, which are catalytically active, has been observed in rare cases, the best defined of which is bovine glutamate dehydrogenase. The enzyme in its native environment, in liver mitochondria, is thought to exist at considerable concentrations, and the associated state must therefore be presumed to be physiologically relevant. The addition of the co-factors, NADH and GTP, favours the depolymerization of the long chains to the smallest active form, which consists of six polypeptide chains, each of molecular weight 50,000. This hexamer is triangular in section, being made up of two superimposed rings of three subunits.

The nature of both the disaggregated and associated forms in solution, and of the equilibrium between them, has been studied by Reisler and Eisenberg, whose work is a salutary reminder of the power of hydrodynamic methods, fastidiously applied by masters of the craft. The first report (*Biopolymers*, **9**, 877; 1970) is concerned in the main with the hexamer and its viscometric behaviour. The determination of the intrinsic viscosity of such a molecule by extrapolation to zero concentration is greatly complicated by the association equilibrium, which causes the disymmetry of the particle to change with concentration. At very low protein concentrations, moreover, measurements, at best tiresome enough, are notoriously vitiated by adsorption of a layer of protein to the wall of the capillary. Reisler and Eisenberg have devised a new and effective correction for this effect, based on the introduction of a factor for the effective diminution of the capillary bore. By this means they are able to extend their measurements to prodigiously low concentrations, and so show that the intrinsic viscosity in the associating system is indistinguishable from that in the presence of the co-factors. These therefore do not function by causing a major shape change. The hexamer has been simulated by machined models, in which each subunit is an ellipsoid of the right shape. The frictional properties of this model in viscous fluids give a calculated intrinsic viscosity in precise agreement with that of the protein, and any geometrical deviations, such as a different monomer shape or a displacement of monomers along the three-fold axis, lead to grossly different values. This is good evidence for the validity of the presumed structure. Reisler and Eisenberg have also made the strange observation that saturation of the solution with toluene greatly promotes the association—a finding altogether contrary to the usual and expected effects of hydrophobic additives.

Reisler, Pouyet and Eisenberg (*Biochemistry*, **9**, 3095; 1970) have also examined the sedimentation properties of the enzyme, and working at modest concentrations, where they can show that non-ideality,

the hydrodynamicist's greatest affliction, can be neglected, find that the sedimentation equilibrium distribution can be represented in terms of a single indefinite association. That is to say, the elongation of the protein rods occurs by addition of successive hexamers according to a single equilibrium constant. Velocity runs lead once more to the same extrapolated sedimentation coefficient as is found in the disaggregated system with cofactors present, and its magnitude agrees with predictions from settling rates of the macroscopic hexamer models.

Olsen *et al.* (*J. Mol. Biol.*, **52**, 239; 1970) have discovered another apparently infinitely associating protein. The enzyme, glutaminase, from kidney, is activated or inhibited by common anions. In Tris buffer the activity and molecular weight alike are lowest; they are higher in phosphate and very high in a phosphate–borate medium. The electron microscope reveals small globular aggregates in Tris, and in phosphate–borate long filaments with a regular helical form, which is shown by shadowing experiments to be left-handed. The formation of helices from the globular state is rapid, and accompanies the onset of high activity. The occurrence of highly aggregated, filamentous, and active forms of enzymes may prove to be a more widespread phenomenon than has been suspected.

CHROMOSOMES

More about Structure and Function

from our Cytogenetics Correspondent

More information about the organization of chromosomes emerged from the third Oxford chromosome conference which was held from September 22–25. Dr M. L. Pardue (Edinburgh) described how ribosomal RNA from *Xenopus laevis* can be hybridized to chromosomes of *Xenopus* and Dipterans to locate the complementary nucleolar DNA sequence. She also described how hybridization can be used to locate the regions of chromosomes bearing "satellite" DNA; in mouse this turns out to be around the centromeres in all the chromosomes except the *Y*. Dr B. M. Richards (London) discussed X-ray diffraction patterns of nucleohistone, which are compatible with a supercoiled structure for interphase chromatin. He outlined a model whereby histone F_{2a1} (which has a known amino-acid sequence) could interact with DNA in such a way as to generate supercoiling. Other DNA–protein interactions were dealt with by Dr T. Holt (Nijmegen). Puffs can be induced by heat treatment at certain regions of *Drosophila hydei* salivary gland chromosomes; at the same time acid proteins are taken up at these regions. The kinetics of protein accumulation can be followed by microspectrophotometry and, together with parallel studies on RNA synthesis at the puff sites, lead to the conclusion that these proteins participate in gene activation. The activity of the *X*-chromosome in the mule has been assessed by Dr M. M. Cohen (Buffalo). In fibroblast cultures from four animals it seemed that in 60–90 per cent of the cells the *X* chromosome of the donkey parent was inactivated as judged by autoradiography, and the degree of inactivation correlated well with the amount of the *X*-linked gene product glucose-6-phosphate dehydrogenase in the cell contributed by each parent.

Reports of mitotic (as opposed to meiotic) crossing over are occasionally encountered in the literature on the genetics of higher organisms. Dr K. Patau (Madison) presented evidence for its occurrence in man. In lymphocyte cultures quadriradial configurations are found, some of which can be considered to be due to mitotic chiasmata. Lymphocytes from Bloom's syndrome show a particularly high frequency of such chiasmate configurations. These chiasmata are non-random in their location in the complement. Patau concludes that the chiasmata arise from pairing of homologues in the somatic cell rather than from translocation.

The way in which studies of meiotic chromosome can reveal chromosome evolution in progress was discussed by Drs M. J. D. White (Melbourne), H. Lewis (Los Angeles) and J. Wahrman (Jerusalem). Wahrman described chromosomes of races of *Acomys* found in Sinai ($2n=36$) and Israel ($2n=38$); the inference is that centric fusion between the telocentric chromosomes of the ancestral population was more complete in the Sinai race. That centric fusion is the origin of the present day chromosomes is strongly inferred from a cross between a race of *Acomys* from Cyprus ($2n=38$) and the Israeli animals. At meiosis in the hybrids a long chain multivalent is formed indicating that centric fusion proceeded in different ways in the founders of these two populations.

The role of *B* chromosomes in the structure of a population of *Myrmeleotettix* has been investigated by Dr G. M. Hewitt (Norwich). Although his investigations ranged from the micrometeorology of the grasshopper's environment to an analysis of the DNA composition of the *B* chromosomes, their role is still unclear. Dr G. M. Evans (Aberystwyth) showed that *B* chromosomes can influence cell division in plants. Evans also revealed a difference in the relation of the duration of the mitotic cycle and DNA content in monocots and dicots. Dicotyledons have longer cycles than monocotyledons even when species with identical DNA content are compared.

Analyses of chromosome movements in meiosis and mitosis were presented by Drs R. Deitz (Tübingen) and A. Bajer (Eugene). The latter showed a film of mitosis in *Haemanthus* endosperm and illustrated how chromosome movement is influenced by a short pulse of ultraviolet light focused onto selected areas of the spindle. From the way in which movement is interrupted, together with changes in microtubule structure, Bajer concludes that the centromere fibrils slide along the continuous fibrils during anaphase.

CELLS

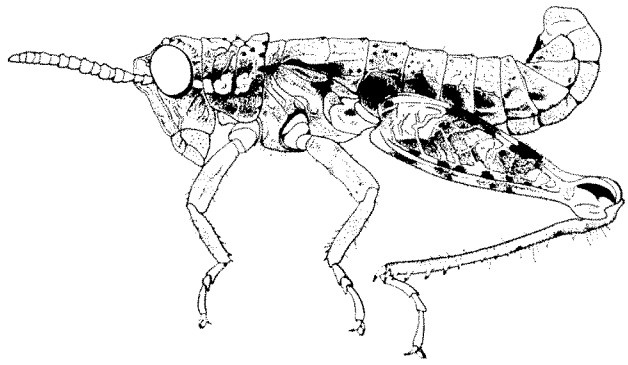
Interactions in Populations

from a Correspondent

The study of cell–cell interactions among mammalian somatic cell populations is growing. Some investigations are at present descriptive, providing evidence for associations between cells without any real understanding of their functional significance. Some workers have invented a form of intercellular cooperation to account for their results but cannot suggest the mechanism involved. At the symposium on cell–cell interactions, part of the meeting of the British Society for Cell Biology held in Birmingham on September 24, examples of both genre were presented. Dr C. N. D.

Cruikshank (University of Birmingham) said that his observations on melanocyte–keratinocyte interaction *in vitro* show that such cells can form an intimate association and that pigmented material can pass from one to the other. Mrs P. Mann (University of Birmingham) described a similar interaction between mast cells and eosinophils; the former in response to an appropriate stimulus, *in vitro*, are capable of transferring granular material to eosinophils.

After outlining the conditions which determine cell fusion, Dr J. F. Watkins (University of Oxford) described the ways in which the formation of heterokaryons and the resulting hybrids can usefully be applied to understanding topics as diverse as the control of mitosis, differentiation, malignancy and the permanence of transplantation antigens. He thought it would be many years before the genetic analysis of mammalian somatic cells by hybridization paralleled the refinements possible with microorganisms.



A more direct approach to cell–cell interaction was presented by Dr D. D. Potter (Harvard University). For several years he and his colleagues have studied the contacts which various kinds of cells can make both *in vivo* and *in vitro*. Experimentally in this latter state it had proved possible to find low resistance junctions between cells at which the cell membrane was greatly modified to permit the passage of inorganic ions, and probably also simpler organic nutrients such as sugars and amino-acids. Such apposition is probably equatable with the tight junction as visualized in the electron microscope. Neither the driving force for the passage of material nor the biochemical nature of the alteration at the junction is known. The methods used for this work included the impalation of cells on micro-electrodes by which their cell potential could be both measured and altered.

Cooperation is a fashionable word in immunological circles, and Dr A. J. S. Davies (Chester Beatty Institute, London) spoke of evidence for the existence of two sorts of lymphocyte (T and B) in mice between which an interaction could facilitate antibody production. He felt that it was not necessary to postulate such interaction in cell-mediated immune responses, but it was likely to be a significant feature of certain kinds of antibody production. Dr A. J. Munro (University of Cambridge) stressed some of the technical difficulties encountered in building appropriate models of the immune response *in vitro*, but indicated that cooperation could be demonstrated which was ostensibly similar to that found *in vivo*. Dr G. Roelants (London) and Dr J. H. Humphrey (National Institute for Medical Research, London) presented the negative and positive aspects of their work on macrophage–lymphocyte interactions. Roelants found that the formation of RNA–antigen complexes by macrophages lacked that specificity which would be required for such materials to play a significant part in immunization. On the other hand, Humphrey showed that in a transfer system, macrophages containing antigen were immunogenic, and that the physiological condition of the macrophages could affect the magnitude of the immune response observed.

Summing up, Dr J. G. Hall (Chester Beatty Research Institute, London) discussed the cytotoxic macrophage and the interaction between cells necessary for it to become "armed" with cytophilic antibody. Hall believed that this form of collaboration between cells was of great significance in the various anti-bacterial and anti-viral immune responses which an organism made in order to survive. Nevertheless, Hall thought that interaction between lymphocytes and endothelial cells in the post-capillary venules, resulting in an alteration of the migration pattern of the lymphocytes, was very important and should be the subject of intense scrutiny.

ENTOMOLOGY

Nymphal Grasshoppers

Five new species, representing four new genera of grasshopper, have been found in South Africa. Describing them in the latest issue of the *Journal of Natural History* (**4**, 493; 1970), H. Dick Brown, of the Plant Protection Research Institute in Pretoria, remarks that they are unusual in lacking wings; this gives them a nymphal appearance. The animal shown here has been named *Namatettix denticornis*.

CHROMOSOMES

Chemistry of Excess

from our Cytogenetics Correspondent

THE extra chromosomes which some plants possess as well as their regular set have been found to influence the chemistry of the nucleus. These effects, described by Kirk and Jones (*Chromosoma*, **31**, 241; 1970), might ultimately effect the physical characteristics of the plants.

Several plants and animals possess chromosomes that are supernumerary to, but not homologous with the regular complement. These are the so called *B* chromosomes. Their origin and function can only be inferred; they contain no mappable genes and they are often deleterious to the individual possessing them, but they are maintained in the population. *B* chromosomes are well known in rye (*Secale*), in which they were studied extensively by Müntzing in the 1950s. Some of their properties have been reinvestigated by Jones and colleagues with respect to their effect on the chemistry of the nucleus.

Kirk and Jones isolated nuclei from root tips of rye plants with between nought and six *B* chromosomes, and measured DNA, RNA, total protein and histone protein within each class of nucleus by microdensitometry. They found that the presence of increasing numbers of *B* chromosomes caused the total protein and RNA content of nuclei to decline while the amount of histone increased. There was a curious pattern to the increase: when the amount of RNA or total protein was divided by the DNA content, the ratio was always lower in nuclei with an odd number of *B*s (one, three or five) than with an even number (nought,

two, four and six) of *Bs*. Conversely, the ratio of histone to DNA was higher in nuclei with odd numbers of *Bs* than in those with even numbers.

At present there is no indication of the meaning of these changes in terms of nuclear function and their relation to the phenotype of the plants. There are some clues, however. There is a negative correlation between histone and both RNA and total protein content within a nucleus, and so *B* chromosomes seem to cause more nuclear histone to be accumulated, and this may in turn depress or repress the nuclear RNA and protein content. And last year Jones and Rees (*Heredity*, **24**, 265; 1969) showed that plants with odd numbers of *B* chromosomes, besides being less frequent in the population, had a weaker phenotype—lower weight and fewer tillers—than plants with an even number of *Bs*. These results suggest that *B* chromosomes cause changes in nuclear chemistry and that these changes ultimately find expression at the level of the phenotype.

Jones and Rees also showed that the presence of *B* chromosomes influenced chiasma formation and inferred that *Bs* increased the genetic variability of the gametes and consequently the offspring—a conclusion that is borne out by other recent studies (Barlow and Vosa, *Chromosoma*, **30**, 344; 1970; Hanson, *Genetics*, **63**, 601; 1969; Malik and Tripathi, *Z. Biol.*, **116**, 321; 1970) of the influence of *B* chromosomes on meiotic behaviour in three monocotyledonous species. In this way *B* chromosomes can compensate, through benefits to the population, for any deleterious effects on an individual.

ECOLOGY

Energetics in the Tropics

from a Correspondent

ENERGY requirements, conversion and utilization provided the central theme of a symposium held from September 16 to 19 at Makerere University, Kampala, Uganda. The proceedings, under the auspices of the International Biological Programme (IBP), embraced the physical and biochemical aspects of energy fixation, the roles and efficiencies of primary producers, herbivores and carnivores and even the energy efficiency of man.

The units in which energy and performance were expressed caused some difficulty. For some delegates, the contribution from Professor J. L. Monteith (University of Nottingham) provided the first experience of applying joules and watts to biological systems, but, at least in his derivation of a light energy conversion efficiency in green plants of 0·01 per cent (taking as 100 per cent the total measurable radiation above the Earth's atmosphere), the choice of units was amply justified. Dr R. Hill (University of Cambridge) then laid the biochemical foundations for a discussion of alternative pathways for carbon dioxide fixation in certain tropical plants.

The importance of production measurements in understanding community structure and interaction was illustrated by the work of the IBP Lake George team and the Nuffield Unit for Tropical Animal Ecology, both based in Queen Elizabeth National Park, Western Uganda. The aim of the former is to construct a complete energy balance sheet for a tropical freshwater ecosystem. Professor C. D. Pigott (University of Lancaster), using data collected in Queen Elizabeth Park, suggested that a knowledge of the primary production of savanna grassland can be used to estimate fairly accurately the site capacity for large herbivores. But he and other speakers stressed that such estimates could be misleading, if expressed solely in total energy equivalents, without taking into account the nutrient content of food, plants in relation to grazing preferences and conversion efficiencies at the second trophic level.

Food energy conversions in animals were discussed in detail by Professor A. T. Phillipson (University of Cambridge), and other speakers dealt with the ecological implications of water use, temperature stress and the inverse relationship between basic metabolic rate and body size. Many animals have obvious adaptations to their environment: the Thomson's gazelle, for example, seems to be highly efficient in its water conservation. Mr. D. Hopcraft (Athi River, Kenya) showed that, under rangeland management, this small ungulate can, at lower production cost, perform better than cattle in terms of lean meat production and yet, even at very high stocking rates, have a less damaging effect on the vegetation than cattle.

Discussing crop production, Professor R. Holliday (Makerere University, Kampala) and others used tea, sorghum, coffee, maize, cotton and legumes to illustrate the concept of economic yield and discussed techniques for manipulating it. Professor M. Dagg (Ahmadu Bello University, Nigeria) emphasized the limiting effects of the availability of water in crop production in the tropics. Another contribution concerned with productivity in East African forests, demonstrated how natural ecosystems can be managed to give economic yield.

A discussion led by Dr D. S. Miller (Queen Elizabeth College, London) brought recommendations that agricultural efficiency could be improved in two ways: by replacing traditional hand tools by more efficient instruments and by improving on the efficiency of man himself. Advances in the latter direction must await a better understanding of the effects of diet, disease and temperature.

The scope of the symposium was enormous, but ecosystems, and especially the less well documented tropical types, cannot be treated narrowly. Although some estimates of community bioproduction were given, many delegates expressed strong opinions that understanding and/or management of ecosystems was only likely to be achieved by intensive studies at the level of the species, some of which were discussed at the symposium.

SELENOLOGY

Source of the Lunar Field

from our Geomagnetism Correspondent

IF the Moon possesses a global magnetic field today it must be a very small field. A few years ago, magnetometers on Explorer 35, for example, showed that there was no measurable field at the altitude of the satellite. Taking into account the limitations of the apparatus used, this can be interpreted as setting an upper limit of 10^{20} gauss cm^3 on the moment of a possible dipole at the centre of the Moon. In other words, the lunar dipole moment is at least six orders of mag-

nitude lower than the terrrestrial dipole moment. But the Moon must have possessed, or at least been influenced by, a fairly strong magnetic field in the past, for some of the material brought back by Apollo 11 contained "natural" magnetization.

Further evidence that the Moon has a magnetic history has come from direct measurement of the field at the lunar surface (Dyal *et al.*, *Science*, **169**, 762; 1970). In November 1969 a three-axis magnetometer was placed on the eastern edge of Oceanus Procellarum by the crew of Apollo 12. The result of the measurements it made can be stated quite simply. During the first twenty days of its operation, the magnetometer recorded a steady field of 36 ± 5 gammas directed 38° below the horizontal and 64° south of east. Any suggestion that this field was produced spuriously by a magnetized artefact was ruled out by the absence of an observed field gradient in the plane parallel to the lunar surface, and by the lack of any change in the field as the lunar module began its ascent for the return to Earth.

What do these data mean? There is a clue in the strength of the observed field. If the field is interpreted as a global dipole, the corresponding magnetic moment comes out at $1{\cdot}7 \times 10^{21}$ gauss cm^3, which is about twenty times greater than the maximum value allowed by the Explorer 35 result. It follows, therefore, that the 36 gamma field must be due to a localized source near the Apollo 12 landing site. The size, shape and depth of the source could, of course, be anything; but calculations show that if it is dipolar and lies near the surface it can stretch no more than about 200 km from the magnetometer site and must possess a magnetic moment between 10^9 and 10^{18} gauss cm^3. These figures are consistent with an extended source having remanent magnetic properties similar to those found in the Apollo 11 samples.

Dyal *et al.* are right, however, to point out that the existence of such a body does not necessarily indicate that the Moon ever possessed a magnetic field. For one thing, the body in question could be a large magnetized meteorite or a region shock-magnetized by meteoritic impact, although the low concentrations of meteoritic material in the Apollo 11 samples militate against such a suggestion. But even if the observed field is produced by a region of native lunar material thermally magnetized in an ambient field, it does not necessarily follow that the ambient field was intrinsically lunar. It could, for example, have been interplanetary, although this is unlikely because, whatever the magnitude of the interplanetary field in the past, directional variations would probably have averaged it out to about zero over the time it took the lunar material to cool through its Curie point. And it is possible that the ambient field was terrestrial.

It is a feature of some theories for the origin of the Moon that the Earth and Moon were once much closer together. If the magnetized body possesses high coercivity, as the Apollo 11 samples do, the ambient field must have been a few thousand gammas. This is the sort of field currently observed at about two to three Earth radii from the Earth, which is dangerously close to the Roche limit for lunar disintegration, although not beyond the realm of possibility. In any case, there is no guarantee that the Earth's field remained constant. A larger terrestrial field in the past would allow the minimum Earth–Moon separation to be increased.

Finally, the ambient field could have been an internal lunar field—an idea which many people hoped the Apollo samples would confirm or refute. But a lunar dynamo implies a hot converting interior and a sufficient lunar angular velocity, neither of which seems to be consistent with the Moon as it is today nor with any stage in its evolution. As far as magnetism is concerned, Apollo has, it seems, raised at least as many questions as it has answered.

TEMPERATURE

Many Methods of Measurement

from a Correspondent

INDUSTRY and government were well represented at the second conference on temperature measurement, held in Warwick from September 21–23. Since the first conference on this topic in 1964 the International Practical Temperature Scale of 1948 (IPTS48) has been revised, and Mr C. R. Barber (National Physical Laboratory) opened the conference with an account of how the new scale (IPTS68) was formulated. Dr T. J. Quinn (NPL) then described how black-body cavities could be made for use above the gold point on the IPTS68, where radiation methods define the scale. Dr J. P. Compton (NPL) explained how the scale can be realized from its new lower limit of 13·8 K up to 273 K, and discussed methods that can be used below this limit.

Mr M. V. Chattle (NPL) described the use of the platinum resistance thermometer between 630·74° C and 1064·43° C—the range of the IPTS68 in which the platinum–platinum 10 per cent rhodium thermocouple is the interpolating instrument. He explained that, as long as care is taken in thermal cycling of the platinum resistance thermometer, it could be used as an interpolating instrument in this range, being far more reproducible than the thermocouple. Mr J. S. Johnston (Rosemount Engineering Co.) explained that the platinum resistance thermometer could be adapted for use in industry, which requires rugged instruments. He showed constructions of thermometers designed for fast response, stability and small size, for use in various environments.

Many speakers described how temperatures, in the range from 300 K upwards, could be measured from the infrared radiation emitted by materials. Mr R. Barber (Land Pyrometers, Sheffield) said that the silicon cell had many uses in radiation pyrometry because it provides a cheap and rugged but sensitive detector. But as he and other speakers explained, care must be taken to ensure that the pyrometer is measuring the required temperature. In steel rolling, for example, difficulties are caused by the oxide layer, by the lack of knowledge of the emissivity and by an environment of steam and electrical interference.

Several speakers described how the temperatures of transparent materials can be measured by choosing the wavelength band carefully. Glasses, polymers and gases have absorption bands in their transmission spectra and so have high emissivity in these bands as well. By isolating these bands with filters and choosing suitable detectors, Mr J. R. Beattie (Pilkington Research and Development), Mr J. M. Rucklidge (Land), Mr B. J. Stay (ICI), and Dr K. C. Lapworth (NPL) were able to measure the temperatures of these materials.

Two sonic methods were among the newer techniques

described. Dr J. F. W. Bell (University of Aston) has used the variation of the velocity of sound with temperature in a solid as the principle behind his thermometer. Mr E. S. Morgan (Central Electricity Research Laboratories, Leatherhead), on the other hand, used this variation in a gas. Morgan used his instrument to measure the average temperature of the gases in a furnace by measuring the time taken for a pulse of sound to travel across the furnace.

VITREOUS STATE

Atoms and Glasses

from a Correspondent

SOME busy experts on the vitreous state managed to fit a Faraday Society discussion on this topic into their conference schedule between September 22 and 24. About half of the contributions presented at Bristol were devoted to electrons or phonons in vitreous materials, and the rest were largely concerned with nucleation, crystal growth and phase separation in glass forming systems. Introducing the electron and phonon section, Professor Sir Nevill Mott (University of Cambridge) reviewed the state of knowledge of conduction mechanisms in amorphous and liquid semiconductors. The existence of localized electron states in these materials has been accepted for some time, and the chief contention centres on the existence and position of the so-called mobility edge, which may divide the electron energy band into localized and non-localized regions. The effectiveness of electron-electron interactions in modifying the already quite complex theoretical picture has also been the subject of much recent discussion. It was taken up again by Professor M. Pollak (University of California) whose chief conclusion was that the interaction can significantly affect activation energies associated with d.c. conductivity in various ways, as well as increasing the a.c. conductivity above a certain critical frequency.

Mr T. Klima and Mr T. McGill (University of Bristol) raised some comment when they dealt with the role of short range order in producing an energy gap in covalent amorphous semiconductors. But, on the whole, phonons sparked off much more discussion than did electrons. Significant theoretical progress is being made on several fronts, for example, with the model based calculations of Bell and Dean, the crystalline approach of Gaskell and the orientationally disordered molecular crystal methods developed by Whalley and his colleagues.

The second half of the discussion was prefaced by Professor J. Zarzycki (Saint-Gobain, Paris) who reviewed phase separated systems. He touched on the failure of some stoichiometric and chemical composition based theories to account for the temperature dependence of miscibility phenomena. He also outlined the basis of the spinodal analysis and remarked on the difficulty in distinguishing between nucleation and spinodal growth mechanisms by small angle X-ray scattering methods; the discussion returned to this difficulty several times.

The significance of Cahn's spinodal analysis was called into question several times, with some particularly pointed evidence for the prosecution coming from Dr R. K. MacCrone (Rensselaer Institute, New York). It is perhaps natural that theories in this area of amorphous research should be inherently more macroscopic or coarse grained in character than those in the realm of electrons or phonons. But there seems to be a growing prospect that the molecular dynamics, or computer simulation techniques already exploited in connexion with simple liquids, can make possible significant progress during the next decade in probing nucleation and miscibility phenomena at the atomic level.

MICROSCOPY

More Scope for Scanning

from our Materials Science Correspondent

FROM a rare laboratory curiosity, the scanning electron microscope has in five years developed into a tool widely used in materials science, microelectronics, biology and even the assessment of lunar dust. Most routine users exploit the instrument in one mode only —the emissive mode, which is used to give information about surface topography. They will be helped to make more varied use of their instruments by D. R. Clarke's recent survey of image contrast in the SEM (*J. Mat. Sci.*, **5**, 689; 1970).

Beginning with the standard emissive mode of image contrast, Clarke distinguishes clearly between back-scattered and secondary electrons and details the special contributions to contrast made by each of these electron types. An important innovation is MacDonald's use of Auger electrons to form an image: this allows highly sensitive atomic number contrast (which is otherwise rather poor in the SEM), and also allows voltage contrast—used for examining microcircuits in operation—to be sharply separated from other forms of contrast. Topographic contrast is interpreted in some detail and the roles of secondary and back-scattered electrons are distinguished.

After a survey of voltage and electric field contrast, of magnetic domain contrast and of beam-induced conductivity contrast, which is used to reveal defects in semiconductors. Clarke surveys very recent developments in distinguishing different crystal orientations. This aspect of image contrast depends on the formation of channelling patterns (a term borrowed from ion-implantation) and indeed the orientation of a crystal can often be determined, though the modest magnification which can be used in this connexion remains a limitation.

Clarke goes on to detail improvements in the collector and display systems (though not referring to the improvement of atomic number contrast which can be achieved by using twin collectors—a Japanese contribution). Electronic processing developed at the Services Electronic Research Laboratory, Baldock, has made it possible for contoured and "quantized" displays to replace simple brightness modulations in images, and a form of stroboscopic display can be used to slow down and display rapid periodic voltage sequences in a microelectronic device.

STRESS ANALYSIS

Computers to the Fore

from a Correspondent

STRESS analysis is one of many engineering subjects which are becoming dominated by digital computer techniques. In this case the technique is finite element

analysis, which simply divides the component under study into elementary shapes (triangles, rectangles and so on) and solves the equations of equilibrium and compatibility by matrix methods. Any conference intended to cover the whole of stress analysis, such as the Institute of Physics Stress Analysis Group annual conference at the University of Surrey on September 23–25, must include this topic to an increasing degree. This certainly happened, but it seemed rather reluctantly done, and reflected the ostrich attitudes of many experimental stress analysts, for whom the Institute of Physics has provided a useful debating ground for many years (the majority of physicists interested in stress analysis are concerned with experimental techniques).

Dr T. K. Hellen (Central Electricity Generating Board) emphasized the success of computer methods for elastic problems, and was supported by Dr J. McEwen (Weir Group Ltd), who had used these programs to solve the centrifugal stressing of impeller blades, and compared the results with other methods. Dr. K. Kedward (Rolls Royce) demonstrated the successful application to anisotropic carbon fibre reinforced beams, describing some very convincing comparisons with photoelastic coating fringe patterns. In this type of application, with anisotropic and non-linear material behaviour, finite element analysis is most promising, for experimental methods bring considerable difficulty in both modelling and analysing this behaviour.

Dr G. C. Mitchell (NCRE, Dunfermline) described some uses of finite elements in ships' structures, showing that it is still necessary to test actual prototypes (or large scale models, at least) to destruction, for practical assessment of failure. Accurate calculation of stresses is only one step in the safe design of large structures.

Several contributors commented on the difficulty of preparing data, and the problem of the vast computer output, which often frightened designers used to decisions based on limited data. The simplification of output for design purposes is an important task.

There were several descriptions of the application of standard experimental techniques to various design and material testing problems, but there were also some interesting developments of instrumentation for high temperature work. Dr V. M. Hickson (Royal Aircraft Establishment, Farnborough) described an ingenious but rather expensive gas gauge, which used the variation of pressure at an orifice to determine small displacements. Stabilization at working temperatures seemed to be difficult, but this did seem a problem with the capacitance gauge, described by Dr B. E. Noltingk (Central Electricity Research Laboratories, Leatherhead), which depended on the change of capacitance between two curved wires, placed side by side, as they were stretched. Preliminary results from this instrument suggested that it is very reliable up to 600° C, and associated instrumentation, described by Dr P. C. F. Walfendale (Automatic Systems Laboratories) could satisfy all practical requirements. For temperatures greater than 600° C, optical techniques seem still to be the only practical, though far from perfect, methods. Dr A. R. Luxmoore (University of Wales, Swansea) described an application of the moiré effect to creep measurements of stainless steel tubes at 800° C.

There was only one description of the application of holography (an elementary study on plates) from Dr K. G. Miles (University of Nottingham). This was surprising, in view of the impact of holography on interferometric measurement of deformation, but perhaps it was attributable to the wide scope of the contributions.

PALAEOMAGNETISM

Can Sediments be Used?

from our Geomagnetism Correspondent

PALAEOMAGNETISM is apparently based on a preposterous premise. Although it is no surprise that rocks which contain small quantities of magnetic minerals can acquire a magnetization, no one had a right to expect that such magnetization could remain stable for hundreds, or even thousands, of millions of years. The reason for the stability is, of course, that some of the magnetic minerals concerned have high coercive forces; and nowhere is this characteristic better illustrated than in haematite-bearing sediments. Very often the natural remanent magnetization (NRM) of red sediments is hardly affected by demagnetizing fields of 2,000–3,000 oersteds.

As far as sediments are concerned, the validity of the palaeomagnetic method is confirmed by consistency of data, as exemplified by close internal grouping of palaeomagnetic directions and comparability of directions with those derived from other types of rock. Nevertheless, a minor stir was created when Smith (R. W.) and Fuller (*Science*, **156**, 1130; 1967) showed that in single crystals of haematite the magnetic moment produced by the interaction of antiferromagnetism with lattice defects and impurities (the so-called defect moment) was much more stable magnetically than the moment produced by the canting of spin sub-lattices (the intrinsic moment). In other words, it seemed that the structure sensitive moment, which can easily be altered by stress or heating to give spurious palaeomagnetic data, was much more stable magnetically than the spin moment, which is less influenced by extraneous phenomena. If this were so, partial demagnetization of the NRM would first remove the very moment which records the true palaeomagnetic direction.

Palaeomagnetists can now breathe freely again, for Dunlop (*Science*, **169**, 858; 1970) has shown that what applies to single haematite crystals does not apply to fine-grain haematite nor to the form of haematite found in sediments. In a long series of magnetic experiments on synthetic haematite powders and natural red sediments in various states of annealing (which removes the defects and so the defect moment), Dunlop has shown that it is the spin-canted moment which is the harder magnetically—and thus that palaeomagnetic directions obtained from sediments partially demagnetized in the laboratory are valid in theory as well as in practice. It turns out that thermal demagnetization should be particularly suitable for the magnetic cleaning of sediments because not only is the average coercivity of the defect moment lower than that of the intrinsic moment, but the process of heating tends to anneal the sample, thereby reducing the number of defects which produce the structure-sensitive moment in the first place.

A Philosophy for Big-Bang Cosmology

by
W. H. McCREA
Astronomy Centre,
University of Sussex

According to recent developments in cosmology we seem bound to find a model universe like the observed universe, almost independently of how we suppose it started. Such ideas, if valid, provide fresh justification for the procedures of current cosmological theory.

MUCH of the effort of current extragalactic optical and radio astronomy is directed to isolating a particular Friedman–Lemaître cosmological model that will reproduce satisfactorily the principal observed features of the universe in the large. Most cosmologists regard this as a meaningful exercise, although they may disagree somewhat as to the particular interpretation to be placed on it. Nevertheless, the Friedman–Lemaître models have not always been treated so seriously since they were first propounded nearly half a century ago. Friedman published his remarkable paper[1] in 1922 in *Z. Physik*, but it seemed to be completely ignored at the time. Lemaître had heard nothing of it when he published his own equally remarkable work in 1927; he did learn of it in time to insert a reference in his paper[2] of 1931. His work, in its turn, was similarly ignored. The two papers, which were in excellent accordance with each other, were rescued from oblivion for rather incidental reasons. Einstein had felt compelled to introduce the so-called cosmical terms into his field relations in order to derive a cosmological model, the Einstein static universe of 1917; he never liked these terms and, when he found out about Friedman's work, he welcomed it as allowing him to discard them and the Einstein universe as well. Contemporaneously, Eddington saw that Lemaître's work showed the Einstein universe to be unstable so that it could be treated as the initial state of an expanding universe; Eddington welcomed Lemaître's work as a way of saving the Einstein universe and the cosmological terms. Now, however, after all these years, it seems that, for the purpose of comparison with the observations, nothing more serviceable than the Friedman–Lemaître models has emerged; they are being taken more seriously than ever before.

The present article arises from an attempt to understand why this is the position. It arose from the circumstance that I have recently had the privilege of occupying the Chaire Georges Lemaître in the University of Louvain, where Lemaître spent almost all his scientific life, so I was brought to reflect afresh on the work of that remarkable man[3]. On the one hand, I came to recognize more than ever the astonishing insight and appreciation of essentials displayed by him—and, of course, by Friedman as well. On the other hand, these two workers had deliberately used as many simplifying assumptions as possible, and yet no one subsequently seems to have gained anything worth while by seeking to relax these restrictions. Surely, therefore, there must be some justification for their work that is deeper than they could have known when they did it. On collecting together recent ideas presented by several writers, this does indeed seem to be the case. If so, the resulting insight must be of considerable interest, although it is still highly tentative.

Another reason for presenting this outlook now is that de Vaucouleurs[4] has published recently an extensive and penetrating criticism of current big-bang cosmology. Taken at its face value, that theory does betray all the apparent weaknesses so unsparingly exposed by him. Nevertheless, so far as it goes, the history of the universe inferred from big-bang theory is self-consistent in so many unexpected ways that it can scarcely be illusory. If the present discussion is valid, it may be claimed to counter much of the criticism expressed by de Vaucouleurs.

Some General Considerations

We begin by asking how cosmology is possible as a scientific study, for scientific study employs physical laws. But the concept of a physical law is that it enables us to treat a system that is being studied as one particular case among many. The universe, however, is a unique system, and so this aspect of a physical law seems to lose all meaning when we attempt to apply it to the universe. Moreover, a "particular case" is usually specified by initial conditions and these in their turn seem to have little meaning for the universe as a whole.

There is nevertheless one consideration that may make the case of the universe in the large different from all other systems in physics. For, if the universe as a whole is evolving, then, of course, the farther away we observe any part of it, the farther back we see it in time. Thus we actually observe the evolution of the universe. Also, if in some appropriate sense one part of the universe is like another, then it might be argued that the various parts make up the many cases needed in order to give significance to the use of physical laws. And a part seen farther away, and so earlier in time, may supply initial conditions for the study of a nearer part.

Such considerations at any rate make it reasonable to try to apply ordinary scientific methods to the study of the universe in the large. Whether this will succeed in yielding results of interest can be known only by making the attempt. In fact, cosmologists have been trying for more than fifty years.

We are, however, compelled to note one possible general difficulty. Manifestly, the farther away we observe parts of the universe (and so the earlier in time) the less information we can get about them. And we certainly could not observe the big bang itself. As we go back in time, therefore, we get less and less information on which to base any predictions until, when we come to what we might wish to treat as the initial state, we have no information at all.

There seems to be only one way in which we might hope that progress would be possible. This would be if we were to discover that, for some reason, we actually require less information than we suppose in order to make desired predictions. We shall see that nature does indeed seem to operate a principle of compensation in favour of cosmologists and that the pursuit of this topic leads us to much fresh insight.

Recent Theoretical Results

In this section, let us provisionally accept at their face value the various physical theories to which we have occasion to appeal; in particular, we take it for granted that they apply to the actual physical world. Afterwards, it will of course be one of our main purposes to examine the status of physical theory in this context.

We recall certain general results of cosmological studies,

R 362

mostly quite recent. (*a*) Hawking, Penrose[5] and their associates have proved some remarkable theorems in the theory of general relativity. Under certain very general assumptions about the behaviour of matter, they showed that any cosmological model admitted by the theory must possess at least one singularity. Any such singularity we should in general regard as a big bang; if there is only one, we should interpret it as "the" big bang.

(*b*) Misner[6] has shown that, if there is one big bang in a homogeneous universe, then even if the circumstances of this big bang are highly anisotropic nevertheless very soon afterwards the model must become highly isotropic. This is brought about by the phenomenon of neutrino viscosity which Misner discovered in the course of the work. Carswell[7] has shown how difficult it is to construct any model that does not conform to Misner's result.

(*c*) If a model universe is everywhere isotropic, it is necessarily homogeneous. The converse is not true, otherwise there would be no point in Misner's result. Also, Misner's result does not allow him to infer isotropy without the assumption of homogeneity, otherwise homogeneity would follow. But it can be argued on physical grounds that a mechanism that tends to produce isotropy must tend also to produce homogeneity. Misner has discussed this aspect[8].

(*d*) Wagoner, Fowler and Hoyle[9] have studied the very early stages of a hot big-bang universe in regard to the nuclear processes operating at each stage. Their work shows in the first place that there is no meaningful sense in which we can speak of an initial chemical composition. A single parameter depending on the hotness and the baryon density is all that signifies. Furthermore, the processes occurring in these early stages produce the raw material for galaxy-formation later on. The chemical composition of this material is the significant chemical composition of the cosmos. The second remarkable inference is that the main features of this composition are not sensitive to the value of the single parameter we have just mentioned: in particular, there is a range of some six powers of ten in the value of this parameter through which the helium abundance (by mass) changes only from about 25 to 35 per cent.

(*e*) Milne[10] long ago remarked that, if we have a cloud of particles in ordinary space, provided only they are not strictly at relative rest, after a sufficient time any particle will see all the rest moving away from himself with speeds proportional to their distances. (By simply waiting long enough, this description must become valid to any desired accuracy.) Thus the time-direction of inevitable ultimate expansion is towards what we call the future, and the Hubble law for this expansion is itself inevitable. In regard to this property, the relativistic treatment does little more than give it a more elegant geometrical form[12].

We may summarize all these conclusions by the statement: (*A*) The universe must start with a big bang (or bangs) and, almost independently of any special initial conditions, it must have a particular chemical composition, it must exhibit a Hubble expansion, it must be isotropic if it is homogeneous, and we do expect it to be homogeneous.

All these predictions seem to be in good agreement with experience. We must comment that they depend on sophisticated developments in various physical theories—general relativity, elementary particle physics, nuclear physics, and so on; this is not elementary cosmology. In the formulation of statement *A*, the "musts" arise from our provisional attitude to the theories; the "almost independently" summarizes various degrees of insensitivity to initial assumptions.

Compensation in Cosmology

In regard to the study of the universe in the large, I now tentatively propound the principle: (*B*) The less information we can get, the less we need in order to make predictions that are confirmed by observation. This may be startling. It implies that, if we ask a sensible question about the universe, but if we necessarily have very little information on which to base an answer, we can nevertheless expect to get a sensible answer by making the best use of what information is available. In any case, so far as the examples given in the previous section are concerned, the proposition *B* states only about the same as *A* when it asserts that certain results follow almost independently of special initial conditions. So proposition *B* is well borne out by those examples. Actually, we shall see later that the number of possible examples of this sort may be quite small.

We must then hasten to state the converse: (*C*) From observed properties of the present state of the universe, we can infer less and less about earlier and earlier previous states, and almost nothing about what we might wish to call the initial state.

By present state, we mean the state of our cosmic vicinity at our cosmic epoch. Statement *C* is then certainly in accordance with our examples. If we are right in saying that, whatever the initial state, a universe must sooner or later show a Hubble behaviour, then, if we do observe a Hubble behaviour, this can tell us almost nothing about the initial state. If we observe the present chemical composition and ask what was the original chemical composition that led to it, then, from what we have seen, this question turns out to be meaningless. But if we observe that the helium content is between, say, 25 and 35 per cent by mass, we can infer that the value of the parameter I mentioned is between 10^{25} and 10^{31} (in the appropriate units) and this tells us rather little ! And so on.

Uncertainty in Cosmology

Some years ago I called[11] attention to some general considerations regarding the uncertainty of inferences in cosmology. The considerations depended on what on general grounds appear to be inevitable limitations on our obtaining the sort of information required in order to make precise inferences. I had to point out, however, that this feature was not yet built into the current formulations of cosmology. So far as the arguments went, I still think they are valid; but I think the discussion given here is complementary. It indicates that the uncertainty is distributed in a quite unsymmetrical way between past and present. On the strength of statements *B* and *C*, it seems that we make the claim, to which I shall return later. (*D*) We can know with a good deal of certainty how the universe is behaving now, but we are quite uncertain as to how it started.

Cosmology Simplified

Perhaps the most immediately significant consequence of this line of thought is that it offers deep reasons for the usefulness of the Friedman–Lemaître cosmological models. As we have remarked, these were based on the most extreme simplifying assumptions—that the universe admits no more than one singularity, that it is homogeneous and isotropic, and so on. In fact, they were toy universes, and they were soon cast aside and almost forgotten, until

Einstein and Eddington recalled attention to them for the rather specialized reasons we mentioned. Then, to everybody's surprise, Hubble, Tolman and others discovered that these toys bore a marked resemblance to the universe revealed by Hubble's observations. Ever since about 1930, a main preoccupation of cosmologists has been to decide which toy universe is most like the real thing. And all this activity, to say the least, has never produced a nonsense.

We may only now be coming to understand why Friedman and Lemaître had wrought better than perhaps they knew—or could know in their day. For from the foregoing discussion we see that, had cosmologists attempted to use more general models not assuming, say, homogeneity and isotropy, then work such as that of Misner would have tended to show that such models would soon become homogeneous and isotropic, and so on as regards other features. Thus cosmologists would, apparently, after all have been led back to the Friedman–Lemaître models.

Uniqueness and Physical Laws

The actual physical universe is by definition unique. As was implied at the outset, a fundamental objection to the procedure of, say, relativistic cosmology is that it compares the actual universe with a whole set of theoretical models, all on the same footing. We are invited to select one of these models that just happens to match better than the rest. It is difficult to assign significance to such a situation.

We have just seen, however, that had we started with models more general than those of Friedman and Lemaître, general physical considerations would have led us to restrict our attention to the more particular cases of the Friedman–Lemaître models. This seems to be enormously significant in the context with which I am now concerned. For, as we have also remarked, further physical considerations of such a sort must be expected to restrict the choice still further. Thus the embarrassing situation of having to select a model universe from among claimants of equal standing may scarcely arise. Or at any rate, if we have to select a model in this way, we should now expect in due course to find some deep physical reason for preferring it.

It is well to remember that the work we are discussing is intended to give at best a model of no more than the "smoothed-out" universe, so some rather artificial features will remain in the situation. Nevertheless, the tenor of the discussion in which we are engaged encourages us to think that we are doing something significant in carrying out the accepted procedures of the subject.

We have noted several properties that a model universe must possess, almost independently of the initial conditions, according to the various physical theories concerned. It seems to be a short step to saying that, according to theory, the actual universe simply has to have these properties. In other words, we think there must be some justification for ignoring any possibility that would follow only from rather special initial conditions. If so, we can assert: (*E*) Physical theory shows that the universe in the large must have certain properties which we observe it does have.

This is not an empty or trivial proposition. As we have already remarked, the examples quoted depend on highly sophisticated physics. By the same token, I am certainly not claiming to be able to say by pure reason what the universe must be like. For physical theory is not the product of pure reason and nothing else.

If statement *E* is significant, then we must further assert: (*F*) In so far as physical theory may be applied to the behaviour of the universe in the large, it must be required to predict only what is observable.

All this provides a new sort of test of physical theory. At one extreme there are the familiar laboratory tests. These are usually very precise, because they concern predictions of a sort that the theory is deliberately designed to yield. At the other extreme, physical theory is not in general designed to make predictions about the universe in the large. If it does, they will be about the smoothed-out universe; for this and other reasons they will not be subject to precise test. But the fact that theory does apparently make generally valid predictions of this uncovenanted sort gives a new kind of confidence in physical theory.

To put the conclusion in perhaps simpler terms: We do not believe that the universe has a singularity (or singularities) because general relativity says it must have; we do not believe the universe to be isotropic because the theory of neutrino viscosity says it must be, and so on. Rather, we believe these theories to be useful ways of thinking about the universe in the large because they lead to these acceptable inferences.

Laws and the Universe

The ideas that are unfolding here may meet two other objections that have been urged against the whole concept of big-bang cosmology. First, it has always seemed that the laws of physics, on the one hand, and the physical universe, on the other, must be interdependent. Any notion that the physical universe came into existence according to certain physical laws—which it, so to say, found waiting for it to obey—seems to be unacceptable. The conclusion *C*, that the laws of physics as we have them permit almost nothing to be said about the "start" of the universe, is certainly in keeping with this view.

Second, the notion of a changing universe evolving according to unchanging laws seems almost as hard to accept. At the same time, the notion of changing laws is useless. Were there such things, we could not know about them. For, if we did know about them, this would be by virtue of a law of change of the laws; this super-law would be unchanging, so we should have a contradiction.

The trend of this new assessment is to regard the laws as being laws explicitly for our study of the universe. The laws are not there to tell us what the universe was doing *n* billion years ago, but to tell us what we can know about this—including, of course, the meaning to be attached to "*n* billion years ago". This viewpoint is clearly consistent with the fact that the certainty of our knowledge is greatest at our present.

It is tempting to say that we could nevertheless go through corresponding theoretical investigations for a time *n* billion years in the past, and so determine what an observer then would have known with certainty. But were we to do this we should still have to find out how much of that knowledge that observer could have transmitted to us. And this is consistent with the demand that we may "predict" only what we can check by observation. We could not check what a past observer would have observed; we can check only what we can observe of what the universe was like at that epoch, as a result of our ability to look into the past in an evolving universe. This should be the same as what the past observer could transmit to us. In this fashion we get away from the concept that physical laws are something that the universe must obey. They are something that our thinking about the universe must obey.

Next Steps

If it is justified to claim that the new outlook enhances the significance of existing studies, we naturally ask how they ought to be developed.

On the astronomical side, it seems proper to continue to seek a Friedman–Lemaître model to fit the observations as well as possible. If one is found that gives a reasonably good fit, then at least it will provide a convenient representation of empirical knowledge of the universe in the large. Also, we know from existing work that we cannot get a fit without allowing for evolutionary effects, and so we expect incidentally to gain knowledge of the evolution of galaxies and so on, that we could gain in no other way.

On the astrophysical side, we ought to look for other properties, such as the helium abundance, that are insensitive to initial conditions, and that do not depend to a first approximation on the "age of the universe". It is not easy to think of such properties, presumably because there are not many of them. Maybe the maximum mass of a galaxy in a cluster is a case in point, or there may be magnetic properties of the cosmos that come in for consideration. The interest is that, just as the instances already discussed apparently serve to narrow down the choice of models to the Friedman–Lemaître cases, additional instances may reduce the choice still further.

We do, indeed, know one fundamental means of discriminating between models of the expanding universe. This concerns the arrow of time. As is well known, Wheeler and Feynman[13] sought to show that, if we take a symmetric combination of advanced and retarded solutions of the equations of electromagnetism, but also take account of the effects produced by a postulated "absorber" at infinity, then the outcome is the same as if we disregard the absorber and follow the usual procedure of arbitrarily selecting the retarded solution for everything in the finite part of the field. Wheeler and Feynman used a static space–time, and it was difficult to understand how a model that is time-symmetric could admit the dissymmetry denoted by selecting only retarded fields. Hogarth[14] therefore sought to adopt these general concepts to non-static space–times. He treated an expanding universe as constituting its own "absorber", in the sense of Wheeler and Feynman, and the expansion provides a natural dissymmetry between past and future. Hogarth discovered that, among the models of the expanding universe that he studied, some do and some do not lead to the emergence of retarded fields. If a particular expanding model does have the property that local electromagnetic effects are correctly treated by the use of retarded fields, then this property would explain why observers in this model would, in fact, describe it as expanding, not contracting.

Were some such results to hold good for the actual universe, since work like Hogarth's again involves sophisticated applications of the physical theories concerned, we should have another striking instance of the ability of the physics to deal with the universe in the large. Further, it would mean, as we have said, that a time-symmetric treatment of electromagnetism (not assuming radiative reaction), that takes explicit account of the behaviour of the universe in the large, would reproduce the same local effects as we get by taking no account of the universe in the large but employing our usual conventions about retarded potentials (and radiative reaction). We do not yet know why we want things to work out that way. The point is, however, that we cannot choose our conventions and our cosmology independently. Thus we seem to be a step nearer to being able to claim that physics as a whole demands just one particular universe.

So far as such work is successful—Hogarth emphasizes the limitations of his treatment and others propose different treatments—it shows how the behaviour of the universe in the large determines local features such as the direction of the arrow of time. Thus we have a "Mach principle" in operation for electromagnetic properties. Now Lynden-Bell[15], in particular, has formulated a criterion for a cosmological model to be "Machian" in a more comprehensive sense. We cannot claim to be compelled to require a model to be Machian. But if we do, Lynden-Bell's work shows that this must impose further severe restrictions.

So far as physics is concerned, our discussion has been concerned with known physics, but we have to ask what new physics may be required for further progress. The change of scale between laboratory physics and cosmic physics is so enormously greater than the change between, say, atomic and laboratory physics that there appears to be abundant scope for new physics. Nevertheless, astronomical observations present no undoubted demand for anything fundamentally new. Astronomers have naturally considered the possibility of new phenomena in galactic nuclei, quasars and pulsars, but there is no definite indication of a failure of known physics. Also, continual creation, or non-conservation of baryon number in certain interactions, if either were required by the astronomy, would be "new" physics, but again there is no firm demand for them, although such ideas are not finally abandoned. Apparently the greatest difficulty of physics is to explain why matter on the small scale is parcelled into identical electrons, identical protons and so on, and why matter on the large scale is parcelled into galaxies and clusters of galaxies. These are very different problems and it might be thought that neither is a cosmological problem. If baryon number, say, is not conserved, however, then the processes in which it changes must be of fundamental cosmological significance; if baryon number is conserved, then the total number of baryons (defined in some appropriate manner taking account of the possible existence of matter and antimatter) is a fundamental feature of the cosmos and a satisfactory theory ought to predict it. Again, the trend of recent cosmological studies is to infer that condensations of matter into galaxies, and so on, exist now because the universe never was homogeneous in detail. Thus the problem of elementary particles and the problem of galaxies are both problems of cosmological origins; proposed solutions would presumably have to be compatible with the conclusion *D* about starting conditions.

Homotypic and Heterotypic Interference by Defective Particles of Vesicular Stomatitis Virus

by
LUDVIK PREVEC
CHIL YONG KANG
Department of Biology,
McMaster University,
Hamilton, Ontario

Defective particles can serve as templates for their replication by helper infectious virus. While both the "long T" and "short T" defective particles in VSV preparations are capable of homotypic interference, only the larger "long T" particle is capable of heterotypic interference.

THE presence of functional non-self-replicating particles is being recognized in an increasing number of mammalian virus systems[1-4]. In vesicular stomatitis virus systems (VSV), defective particles, produced as a natural consequence of infection with the bullet-shaped infectious "B" particles, are responsible for autointerference (which results in decreased yields of infectious viral progeny)[5-7].

Defective particles, designated "short T" particles, are produced by wild type VSV of the Indiana serotype (IND-ST) whereas a larger "long T" particle is the only defective particle produced by a heat resistant strain of VSV (HR-LT) isolated from the above strain[8,9]. Both "short T" and "long T" particles are similar in morphology[8,9] and constituent proteins[10,11] to the larger infectious B particle. Whereas "short T" particles are one-third the length of B particles and contain an RNA genome one-third the weight of the B particle genome, the "long T" particles are approximately one-half the length of B particles and contain an RNA genome one-half the weight of the B particle genome[9,12,13].

Huang and Wagner[5] showed that "short T" particles of the Indiana serotype, while capable of interfering with the production of infectious virus of the Indiana serotype (homotypic interference), are much less effective in interfering with the production of infectious virus of the New Jersey serotype (heterotypic interference). We here compare homotypic and heterotypic interference by both "short T" and "long T" particles of the Indiana serotype and propose a model of the possible genome composition of the defective particles.

Preparation of B and T Particles

Pure B particle stocks of the HR-LT and IND-ST strains of the Indian serotype[9] and B particles of the New Jersey serotype were produced by low multiplicity passage (0·1 p.f.u./cell) of plaque purified virus in mouse L cells in culture. Electron microscopic examination of these stocks reveals less than one T particle in one hundred B particles. At least three high-multiplicity serial passages are required to produce a detectable number of T particles.

"Long T" particles were prepared from lysates of serial undiluted passage stocks of HR-LT virus; "short T" particles were obtained from lysates of undiluted passage stocks of IND-ST strain of VSV. Both "long T" and "short T" particles were separately purified by at least three consecutive sucrose gradient purifications. The final infective titre in T particle preparations was less than 10^4 p.f.u./ml.

Interference by Purified "Long T" and "Short T" Particles

The yield of infectious virus produced by cells infected with B particles together with either "long T" or "short T" particles depends on the multiplicity of defective particles added. At low multiplicities of T particles, where the interference effect is least, there is a near linear relationship between the log of the p.f.u. produced and the dilution of the T particle preparation. This linear portion of the interference curve is used as a measure of the interfering activity[17].

In Fig. 1 the interfering activities of both "long T" and "short T" particles with B particles of three virus strains are compared. The interfering activities of both "long T" and "short T" particles are identical when tested against homotypic B particles. By contrast, whereas "long T" particles are as effective in heterotypic as in homotypic interference, the "short T" particles did not produce heterotypic interference.

Particle Production during Interference

The interference assay determines the effect of interference on infectious B particle production only. Consequently, experiments were done to examine the entire extracellular particle yield by quantitation with measurement of absorbance, after sucrose gradient analysis, for each condition of interference. Infection with "long T" or "short T" particles alone, at the highest concentrations

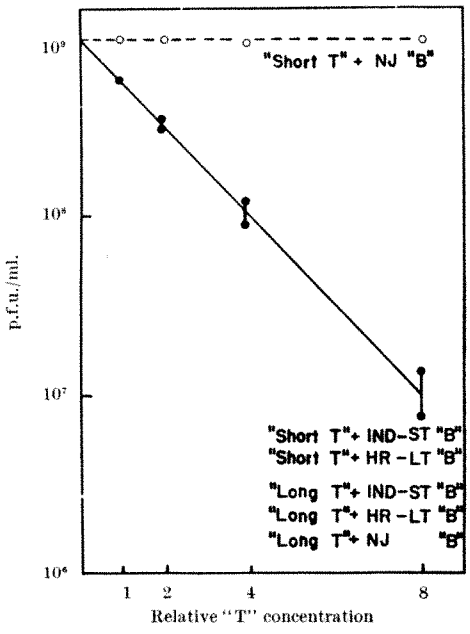

Fig. 1. Interference by "long T" and "short T" particles of the Indiana serotypes. L cell monolayers, 4×10^6 cells in sterile 60 × 15 mm Falcon plastic Petri dishes, were infected with 4×10^6 p.f.u. of B particles of the appropriate strain in 0·1 ml. A similar volume of either growth medium or appropriately diluted "long T" or "short T" particle stock was also added to each plate. After absorption at 37° C for 30 min in an atmosphere of 5 per cent CO_2 and 100 per cent humidity, 5 ml. of minimal essential medium supplemented with 5 per cent foetal calf serum was added and the plates were incubated a further 18 h. At this time the yield of p.f.u./ml. in each cell free lysate was determined by plaque assay[18]. At least three different experiments were done for each particle combination using two distinct "long T" and "short T" preparations. For each T particle preparation the relative numbers of "long T" in the same volume of preparation were determined by direct microscope counting and the dilution scales normalized. In the above graph a relative dilution of 2 corresponds very approximately to one physical T particle per cell. All results are normalized to a control particle yield of 10^9 p.f.u./ml. to allow direct comparisons. The solid line and associated bars show the range of results obtained for the following five combinations: "short T" or "long T" particles with homotypic HR-LT or with IND-ST particles and "long T" with heterotypic New Jersey B particles. The broken line (○ - - - ○) represents the results of "short T" with heterotypic New Jersey B particles.

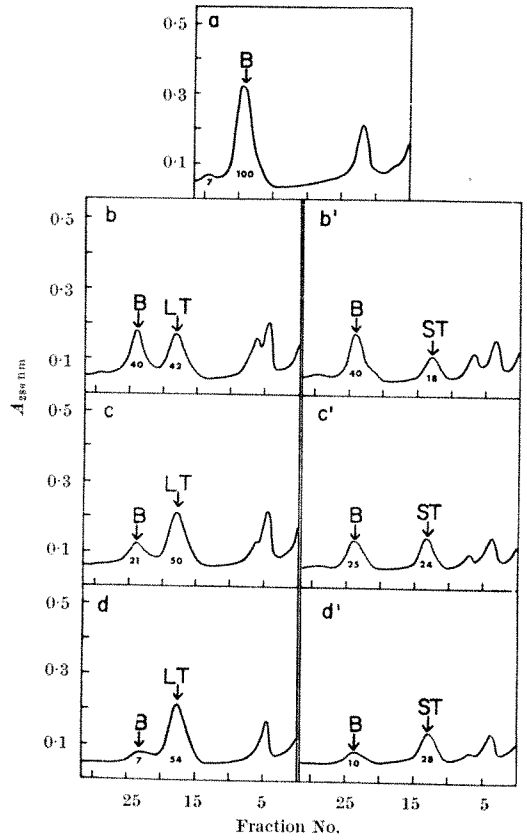

Fig. 2. Effect of "long T" and "short T" particles on the total particle yield of cells infected with IND-ST strain. 10^8 cells were infected with 1 p.f.u. cell of IND-ST B particle stock with or without the addition of appropriately diluted T particles. After absorption for 30 min at 37° C the cells were resuspended (10^6 cells/ml.) and incubated in suspension culture for 24 h. Cells and debris were removed from the lysate by centrifugation at 2,000*g* for 10 min. Virus particles were pelleted from the supernatant by centrifugation at 40,000*g* for 120 min in a Sorvall fixed angle rotor, resuspended in 1 ml. of phosphate buffered saline (PBS) and layered on a linear 5 to 30 per cent sucrose gradient in PBS. After centrifugation at 81,000*g* and 4° C for 35 min in the 'SW27' rotor of a Spinco ultracentrifuge, the gradients were collected and the effluent was continuously monitored for A_{280} using an Isco density gradient fractionator. *a*, Yield from cells infected with B particles alone; *b*, *c*, *d*, yield from cells infected with B particles plus two-fold increasing numbers of "long T" particles respectively; *b'*, *c'*, *d'*, yield from cells infected with B particles and two-fold increasing numbers of "short T" particles. The direction of sedimentation was from right to left. The numbers below the peaks are proportional to the area under the peak and are normalized to a value of 100 for B particles in *a*.

used in this study, yielded neither light scattering nor absorbance bands.

In all gradients illustrated, the position of B particles, "long T" particles or "short T" particles is indicated. Absorbance peaks located at other positions in the gradient will be briefly described. Electron microscopic examination of material in fractions sedimenting just in advance of the B particle revealed only clumps of particles identical to infectious B particles. In some gradients a shoulder of absorbance appears on the trailing edge of the B particle band, but the nature of this material is unknown. Near the top of the gradients there are one or more bands of material which in the electron microscope contain structures similar to the core nucleoprotein of B and T particles. Ribonucleoproteins of both B and T particles accumulate in infected cells[9] and are released to the extracellular medium late in infection.

Fig. 2 shows the particle yield from cells infected with B particles of the IND–ST strain and either "long T" or "short T" particles. With either T particle it can be seen that the greater the input of T particles the less B particles produced, as expected from p.f.u. results. At lower levels of interference the mass loss in B particles is partially compensated by an increase in corresponding T particle production. At high levels of interference, however, the actual mass of particle production is in fact decreased. This is in keeping with observations of viral RNA synthesis as described by Stampfer *et al.*[14].

An important conclusion can be drawn from the results presented in Fig. 2. Although the IND–ST strain of VSV, in normal undiluted passage conditions, gives rise principally to "short T" particles, it can—when superinfected with "long T" particles—lead to their replication. This suggests that the defective particle is acting as a template, presumably at the RNA replication level, for its own synthesis.

Identical results were obtained when the above experiments were repeated using the homotypic HR–LT strain of B particles with either "long T" or "short T" particles. Simultaneous addition of both "long T" and "short T" particles to cells infected with IND–ST B particles resulted in the production of both types of T particles (unpublished data).

When "long T" particles were used in heterotypic interference (Fig. 3*b*, *c*, *d*) there was a progressive reduction in the number of B particles produced as the input number of "long T" particles increased. By contrast with homotypic interference, however, there was only minimal indication of T particle production. If "long T" particles are indeed produced in this infection, their number is not related to the input number of "long T" particles.

"Short T" particles used in heterotypic combination with infectious B particles of the New Jersey serotype have no effect on the yield of B particles (Figs. 3*b'*, *c'*, *d'*) as expected from the lack of interference determined by p.f.u. At the same time it should be noted that no con-

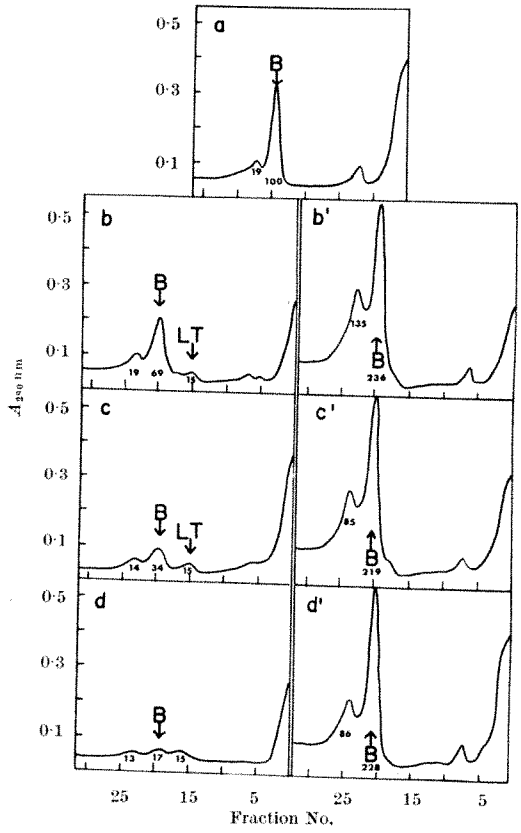

Fig. 3. Effect of "long T" and "short T" particles on the particle yield of heterotypic New Jersey B particle infected cells. The procedures are identical to those described in Fig. 2 except that B particles of the New Jersey serotype were used. All cultures were harvested at 24 h. The virus particles of *b'*, *c'*, *d'* were pelleted by centrifugation at 81,000*g* for 70 min in a Spinco 'SW 27' rotor and somewhat greater particle recoveries were obtained than in *a*, *b*, *c*, *d* which had been pelleted as described in Fig. 2. *a*, Yield from cells infected with B particles alone; *b*, *c*, *d*, yield from cells infected with B particles plus two-fold increasing numbers of "long T" particles; *b'*, *c'*, *d'*, yield from cells infected with B particles plus two-fold increasing numbers of "short T" particles. The direction of sedimentation is from right to left. The numbers below the peaks are proportional to the area under the peaks normalized to a value of 100 for B particles in *a*.

comitant synthesis of "short T" particles occurred in these conditions. Thus the New Jersey virus seems incapable of acting as a helper for synthesis of "short T" particles of the Indiana serotype. This result was not the result of exclusion of "short T" particles from the cell by New Jersey B particles, for pre-infection with "short T" particles gave the same result.

Possible Cistron Assignments for VSV Genomes

The fact that ultraviolet irradiation can eliminate the interfering effect of "short T" particles and "long T" particles (unpublished observations) seems to indicate the need for functional T particle genomes in interference. The question is therefore: What information is carried by the T particle genomes? As a working model we propose that the genomes of B, "long T" and "short T" particles consist of the cistrons as shown in Fig. 4. This model is based principally on a consideration of the molecular weights of the viral structural proteins[10,11] and the molecular weights of the RNA genomes within the three particles[9,13].

Although the polymerase cistron is shown as one unit, the replicase and transcriptase (production of messenger RNA) can be different enzymes or different functions of the same enzyme. Furthermore, partly on the basis of a previous conjecture that each structural protein is coded for by its own monocistronic messenger RNA[9], we may suppose that the genetic information in the T particle is complementary in base sequence to the actual messenger RNA for these proteins. On the basis of these cistron assignments, the lack of self-replication by T particles is explained by the absence of the polymerase cistron. Replication of T particles in the presence of B particles can occur if the viral replicase specified by the B particle genome is capable of replicating the T particle genome.

At least two hypotheses for interference have been previously proposed. One suggests[5] that a product of the T particle genome may act as an inhibitor of an essential "early" protein coded for by the B particle genome. The second hypothesis suggests that the T particle genome may compete with B particle RNA as a template for available polymerase molecules[14]. To distinguish between these possibilities on the basis of the model it will be necessary to determine whether T particles, like B particles[16], carry a virion-associated transcriptase or if transcription from T particle genome is wholly dependent on an enzyme synthesized from the B particle. In particular, it will be important to know whether "long T" particle RNA is replicated in the presence of New Jersey B particles.

Regardless of which mechanism is operative in interference the proposed cistron assignments afford a possible explanation of the difference in heterotypic interference exhibited by the two T particles. Assuming that VSV

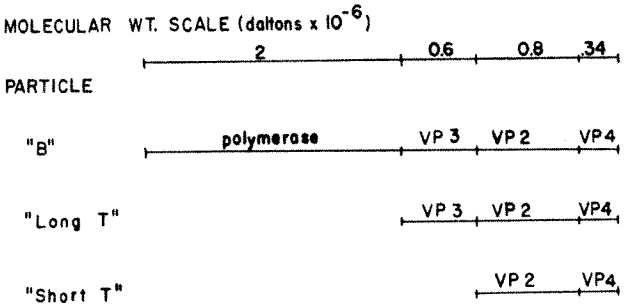

Fig. 4. A proposed model of the cistrons in VSV particles. VP_3, VP_2, and VP_4 refer to the viral structural proteins as previously defined[10]. Apart from the grouping of the cistrons of VP_2 and VP_4 and the grouping of these cistrons with that of VP_3, the linear arrangement of these cistrons along the genome is arbitrary. The expected cistron sizes are derived from the molecular weights of structural proteins as obtained by Wagner *et al.*[11] multiplied by ten. The molecular weights of the genomes are from Nakai and Howatson[13] and Petric and Prevec[9].

polymerase is specific for homologous template RNA, then—because the proteins VP_2 and VP_4 are antigenically distinct in the two VSV serotypes[15]—we suggest that the New Jersey enzyme is incapable of utilizing the RNA contained in the "short T" genome. In this case no interference could occur. The "long T" genome, however, contains the cistron for VP_3, a protein which is antigenically similar in both serotypes[15]. This segment of genome may be sufficiently similar in the two serotypes to allow template recognition and subsequent replication or transcription of all cistrons thus leading to interference.

This work was supported by grants from the National Research Council of Canada and the National Cancer Institute of Canada. We thank Dennis Takayesu for technical assistance.

Interferon Production by T4 Coliphage

by
W. J. KLEINSCHMIDT
R. J. DOUTHART
E. B. MURPHY
The Lilly Research Laboratories,
Indianapolis, Indiana 46206

Evidence is presented that DNA can act as an inducer of interferon.

ALTHOUGH interferon is produced by cells in response to a number of agents, the recognition mechanism of the cell to the inducer, along with subsequent events involved in the production of interferon, is little understood. Viruses, both active and inactivated, are capable of inducing interferon. A phage produced in a mould, *Penicillium stoloniferum*, was found in our laboratories to be the active component of statolon[1,2]. Subsequently, Lampson *et al.*[3] showed that double-stranded RNA extracted from a helenine preparation obtained from *Penicillium funiculosum* was a highly active inducer of interferon. Our studies, and those of others, have shown that such double-stranded RNA is derived from phages (mycophages) carried by these moulds[4,5]. Synthetic double-stranded RNA molecules were also found to be capable of inducing interferon[6].

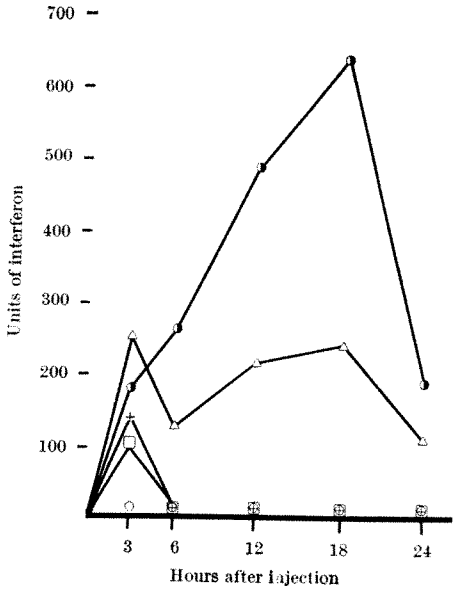

Fig. 1. Production of circulating interferon with T4 and endotoxin. ◑, T4; △, T4+endotoxin; +, endotoxin, heated and sonicated; □, endotoxin; ○, T4, heated and sonicated.

Although DNA viruses can induce interferon and are inhibited by it, DNA, although double stranded, has not proved to be an effective inducer[7]. DNA very likely does not reach the inducer recognition site *in vivo* because of its vulnerability to nucleases or possibly because of structural restrictions. Recently, Friend *et al.*[8] demonstrated that T2 coliphage is taken up and degraded by macrophages. In an attempt to understand more about the mechanism of the stimulation of interferon production, we undertook to determine whether T4 coliphage, a DNA containing virus of nonmammalian origin, and presumably nonreplicating in the mammalian cell could, by virtue of its being a virus, deliver its DNA to the recognition site.

T4 coliphage (T4r) was grown in glycerol medium[9] and titred according to classical methods[10]. Lysates were freed of bacterial debris by filtration or centrifugation, dialysed overnight against three volumes of distilled water, applied to 6 × 70 cm DEAE-cellulose columns, and eluted with a salt gradient (personal communication from D. Fraser). The eluted phage band was pelleted by centrifugation at 15,000 r.p.m. in the 30 rotor on the 'Spinco Model L' centrifuge. The pellet was carefully resuspended and diluted in 0·15 M NaCl, 0·001 M $MgCl_2$ and 0·001 M Tris buffer (*p*H 6·8).

The serum of mice injected intravenously with 2×10^{11} T4 coliphage particles/mouse and bled 18 h after injection was found to be inhibitory to vesicular stomatitis virus (VSV) in mouse L cells. Levels of inhibition in several experiments ranged from 500 to 1,000 units/2·5 ml. serum. Examination of the properties of the inhibitor showed it to be a nonsedimentable, nondialysable, *p*H 2 stable, pepsin-sensitive, species-specific substance, all of which are properties of interferon. The presence of interferon could not be detected in the sera of mice injected 48 h previously; this disappearance with time is generally observed with circulating interferon. Preliminary experiments with T4 DNA showed no production of an inhibitor against VSV in mice injected with DNA and bled 18 h later.

A dose response was determined by injecting intravenously five groups of four mice each with 0·2 ml. of purified T4 coliphage, ranging in dosages from $3{\cdot}60 \times 10^8$ to $1{\cdot}84 \times 10^{11}$ particles/mouse. At 18 h after phage administration, the mice were bled and the sera from each group were pooled and assayed for interferon. The results given in Table 1 show an increased response with increasing quantities of T4 coliphage. No response is seen with T4 until a threshold input of about 3×10^9 particles/mouse

Table 1. DOSAGE RESPONSE OF T4 COLIPHAGE IN MICE

Phage particles per mouse	Units of interferon
$1{\cdot}84 \times 10^{11}$	742
$3{\cdot}60 \times 10^{10}$	159
$1{\cdot}18 \times 10^{10}$	145
$3{\cdot}60 \times 10^{9}$	85
$1{\cdot}18 \times 10^{9}$	< 30
$3{\cdot}60 \times 10^{8}$	< 30

is reached. Lomniczi and Burke (personal communication) have made a similar observation with mutants of Semliki Forest virus. At high multiplicities the RNA of the input virus was the inducer, while at lower multiplicities the inducer was newly synthesized RNA. It seems that interferon synthesis can begin only when the concentration of inducer reaches a threshold concentration whether by initial input or by subsequent increase through synthesis.

Although the T4 phage was of high purity, the possibility of extraneous endotoxin being responsible for interferon production needed to be eliminated. Endotoxin is a relatively stable material—preliminary experiments showed that endotoxin (*Escherichia coli* O111: B4 endotoxin, Difco) withstands heat treatment at 98° C for 15 min plus sonification for 15 min, while T4 is inactivated as an inducer by this treatment. A differential test was therefore available.

T4 at 3×10^{11} particles/mouse and endotoxin at 150 μg/mouse, both untreated and treated with heat and sonication, were each administered intravenously to groups of six mice, and after various time intervals they were bled. The sera of each group of mice were pooled and were then assayed for interferon. A mixture containing equal volumes of the starting materials, T4 and endotoxin, was also tested. Because injection volumes were held constant (0·2 ml.), half quantities of each of the constituents were injected in the latter case.

Endotoxin, both treated or untreated (Fig. 1), produced an early peak interferon followed by a swift decay, as is generally seen with endotoxin[11]. Although some interferon is seen early with T4, it continues to increase with time until a peak level is reached at 18 h. This late peaking is seen with viral inducers of interferon. No detectable interferon is produced with T4 inactivated by heat and sonication, indicating that no measurable endotoxin contaminates the phage preparations. The curve of the mixture of T4 and endotoxin also shows the characteristic contribution made by each component and that the contribution is additive at 3 h. Closer definition of the kinetics of interferon production by T4 during the early period was desirable, and this was included in the next experiment.

Because ghosts of the T-even coliphages can be prepared, we had available a method for testing the contribution of the particulate coat of T4 toward the production of interferon. T4 ghosts were prepared according to the procedure of Herriott and Barlow[12]. Ninety-four per cent disruption was accomplished with three osmotic treatments. T4 at 3×10^{11} particles/mouse, and an equivalent amount of T4 ghosts, less 6 per cent, prepared from the same sample of phage were injected. Because some intact phage remained in the ghost preparation, T4 at the same concentration ($1{\cdot}8 \times 10^9$ particles/mouse) served as a control.

As can be seen in Fig. 2, T4 particles bereft of their DNA do not make a contribution toward production of interferon in the mouse. The interferon that is produced obviously results from the intact T4 present in the preparation. Again a peak level of interferon production is reached 18 h after injection of the T4. It can be seen, however, that with the closer defined points during the early period, a separate early peak is produced by T4 at 2 h with a characteristic decay.

Early experiments in this study had indicated that extracted T4 DNA was not active as an inducer. It was examined again over a wider range of concentration and time. Quantities of phenol-extracted DNA equivalent

to that found in 1×10^9 to 3×10^{11} phage particles were injected into mice, and their sera were tested for interferon. Only at the high concentration equivalent to 3×10^{11} phage particles at 2 h after injection was any inhibition seen, and the quantity of interferon produced was relatively low.

Inducers of interferon are generally divided into two classes; the endotoxin or releaser type and the viral or inducer type which leads to *de novo* synthesis of interferon. Although endotoxin was found not to be involved in the production of interferon by T4, the early peak at 2 h indicated toxicity and possibly, therefore, release of interferon from the cells, rather than stimulating *de novo* synthesis. The kinetics of interferon production at a later time, with the main peak at 18 h, indicates that this interferon is newly synthesized. The appearance of interferon at 18 h could, however, be a reflexion of a slow uptake and degradation of the particle.

The best method for differentiating between release or synthesis of interferon is to test the ability of the inducer to produce interferon in tissue culture. Endotoxin is not capable of producing interferon *in vitro*, while viral inducers possess this capability. When T4 was tested in mouse L cells and challenged with VSV after 24 h, no evidence of protection was seen. But when it was applied to monolayers of primary rabbit kidney cells, a cell which takes up materials much more readily, inhibition of VSV was clearly demonstrated (Table 2). This system was not sensitive enough to detect exogenous interferon in the supernatant fluids. The cells were thoroughly washed (four times) before infection, however, to remove nonspecific inhibitors, and we relate the inhibition to interferon and conclude that the inhibitor that makes its appearance late in mice after injection of T4 coliphage is newly synthesized interferon.

Our data show that T4 coliphage is capable of inducing interferon. When the component parts of the phage particle, both the protein coat and the DNA, were tested separately, however, they failed to induce interferon. Thus there was no possibility of the presence of contaminating materials, such as endotoxin. These data require an explanation for interferon induction by T4 phage.

The protein portion of the phage in our estimation is not a strong contender as an inducer. This follows from the fact that T4 ghosts were not capable of stimulating interferon. The morphology of phage coats, as seen from electron micrographs of our preparations, is not altered appreciably by osmotic shocking. Coliphage ghosts retain their basic anatomical features and chemical constitution[13,14]. Their uptake should not therefore be altered from that of the phage particles themselves. If the coat of the intact phage was active initially as a stimulator of interferon, it should remain so. The lack of stimulation of interferon by T4 ghosts not only is evidence against the protein of T4 as the inducer but also rules against the particle *per se* being responsible solely because of its particular nature.

The situation with DNA is, however, entirely different. Inside the phage, the DNA is present as a closely packed unit and will readily be taken up as such. Outside the phage, the DNA occupies much greater space. Such expansion of the molecule would impede its uptake. The DNA in solution would also be exposed to degradation by DNase and by shearing. Encapsulation would protect the DNA against such degradation.

T4 phage, by virtue of its being a viral particle, may be channelled through a route generally taken by viruses after uptake. This would facilitate the delivery of the

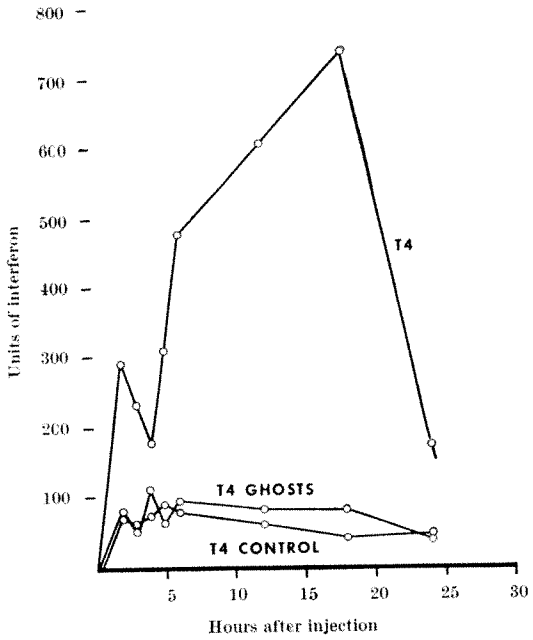

Fig. 2. Production of circulating interferon with T4 and T4 ghosts.

DNA to the inducer recognition site. On uncoating the phage at this stage, the DNA in its unaltered state would be able to initiate the sequence of events leading to interferon synthesis.

Colby and Duesberg[15] have recently reported the isolation of a double-stranded RNA from vaccinia-infected cells. Their observation has provided a mechanism for the stimulation of interferon synthesis by mammalian DNA viruses, namely, through the mediation of a double-stranded RNA. Jurale *et al.*[16] have also observed a double-stranded RNA in T4 infected *E. coli*. It is possible, although unlikely, that the DNA of T4 coliphage can also initiate the synthesis of a DS-RNA in mammalian cells.

Glucosylation of the T4 DNA may also be an important structural feature for activity, in distinction from other DNAs that have been tested. The extracted DNA, of course, remains glucosylated, but here the DNA may be decreased by degradation or by diminished uptake to a point below its effective concentration, while it remains intact while encapsulated.

The strict structural specificity required for a molecule to be active as an inducer of interferon[7] may be inherent in the structure of T4 DNA as it exists in intact phage. An exceedingly important observation pertinent to our argument is that of Maestre and Tinoco[14]. From optical rotary dispersion studies on a number of phages, including T4, and their nucleic acids, these investigators conclude that the DNA inside a phage does indeed possess a different conformation from the DNA in solution. Release of the DNA from the T4 phage before its reaching the recognition molecule may then result in a conformational change accounting for the failure of extracted T4 DNA to induce interferon. We therefore submit that DNA is the component molecule of T4 coliphage responsible for induction of interferon and that this is made possible through the delivery of the T4 DNA in the required configuration to the inducer recognition site, implemented through the encapsulation of the DNA in the intact phage. DeClerq *et al.*[17] have recently made an observation that supports this structural transition hypothesis. They have found that synthetic double-stranded polydeoxyribonucleotides acquire interferon-inducing capacity only after heating at 37° C before application to cells. They suggest that this activation is caused by changes in secondary structure of the polynucleotides.

We thank Dr G. B. Cline of the University of Alabama

(Birmingham) for highly purified T4 coliphage preparations supplied at the beginning of our study, Dr L. F. Ellis for electron microscopic examination of T4 coliphage and T4 ghost preparations, and Mr E. L. Hayes, Mr F. Beasley and Mr F. Streightoff and his group for assistance.

The Renin–Angiotensin System: Inhibition of Converting Enzyme in Isolated Tissues

by

J. W. AIKEN

The converting enzyme content of isolated tissues suggests that the indirect action of angiotensin I involves the intramural generation of angiotensin II. Inhibition of the enzyme shows that there is also a residual, direct action of angiotensin I.

SKEGGS and his colleagues[1,2] have shown that there are two angiotensins, the decapeptide angiotensin I (A I), from which the second and more active octapeptide angiotensin II (A II) can be generated by a "converting enzyme" isolated from plasma. Ng and J. R. V.[3,4] found that *in vivo* the plasma converting enzyme was relatively inactive and that AI was converted to A II on transit through the pulmonary circulation. A I was also converted to A II in isolated lungs perfused with Krebs solution[5], so the enzymic activity was in the lung tissue and was not due to activation of the plasma enzyme on its way through the lungs.

In other vascular beds, such as kidneys or hind legs[3–5], there was only a net inactivation of A I and A II. Nevertheless, homogenates of various tissues show converting enzyme activity[6–10]. Thus A II might be formed in these tissues but in amounts too small to be detected in the fluid or blood perfusing them. Alternatively, converting enzyme activity of tissue homogenates might be due to endopeptidases liberated by maceration but not normally available to A I when the tissues are intact.

On isolated organs bathed or perfused with salt solutions, A I has similar effects to A II but is less potent[1–4,11–14]. In isolated organs such as the rabbit aorta[11], the rat colon[3,4] and the rat uterus[14], A I has 2–10 per cent of the potency of A II but in some perfused organs[12,13] and in guinea-pig isolated ileum[12] A I is up to 70 per cent as active as A II. This variation in the relative potency of A I may be due to one or more of three modes of action: (1) a direct action on specific A I receptors, (2) a direct but weak action on A II receptors, or (3) an indirect effect due to a variable conversion to A II within the isolated tissue itself.

We have now distinguished between these possible modes of action of A I by using an inhibitor of converting enzyme[5,8,15] found in an extract[16] of *Bothrops jararaca* venom. A pentapeptide in the extract with the structure pyroglutamyl–lysyl–tryptophyl–alanyl–proline[17] also inhibits converting enzyme *in vitro*[18]. A synthetic sample (SQ 20,475) of this pentapeptide was kindly supplied by Dr M. Ondetti and J. Pluscec of the Squibb Institute for Medical Research.

Angiotensin I used was the Ileu[5] synthetic decapeptide (Schwartz Biochemicals) and angiotensin II was the Asp[1]-β-amide, Val[5] angiotensin II (Hypertensin, Ciba). All drugs were dissolved in sterile physiological saline solution (0·9 per cent NaCl w/v) and administered by slow infusion (0·03–0·3 ml./min) into the perfusion or superfusion fluid. Drug concentrations are expressed as the free base or peptide and refer to the amount of substance in the perfusion or superfusion fluid. Contractions of isolated tissues were detected by isotonic transducers and recorded on a Watanabe 6-channel pen recorder.

Inhibition of Converting Enzyme

We first established that the synthetic pentapeptide inhibited converting enzyme of guinea-pig isolated lungs. Lungs were perfused through the pulmonary artery with Krebs solution at 37° C and 10 ml./min as previously described[5]. The effluent from the lungs superfused[19] up to six isolated tissues, including rat colons[20] and rat stomach strips[21]. These tissues were selected because they are contracted by low concentrations of A II but are relatively insensitive to A I. To increase the specificity of the bioassay for A II, a mixture of antagonists (methysergide bimaleate (200 ng/ml.), phenoxybenzamine hydrochloride (100 ng/ml.), propranolol hydrochloride (2·3 μg/ml.), hyoscine hydrobromide (100 ng/ml.) and mepyramine maleate (140 ng/ml.)) was infused into the Krebs solution after it had perfused the lungs. This had an additional beneficial effect of reducing the spontaneous activity of the bioassay tissues.

The pentapeptide strongly inhibited the converting enzyme activity of guinea-pig lungs as shown by contractions of a rat colon superfused with the effluent from the lungs (Fig. 1). The first three contractions were induced by A II (0·3, 1 and 3 ng/ml.) given directly to the assay tissues. When A II (3 ng/ml.) was infused through the lungs, its activity on the rat colon was scarcely reduced indicating, as shown previously[5], that A II was not inactivated in the pulmonary circulation. A I (10 ng/ml.) had little or no effect when infused directly to the assay tissues but when infused through the lungs at 3, 5 and 10 ng/ml. the contractions of the rat colon showed that there was about 50 per cent conversion of A I to A II. When the pentapeptide (SQ 20,475, 0·5 μg/ml.) was infused through the lungs, conversion of A I to A II was reduced to less than 10 per cent. During infusion of the

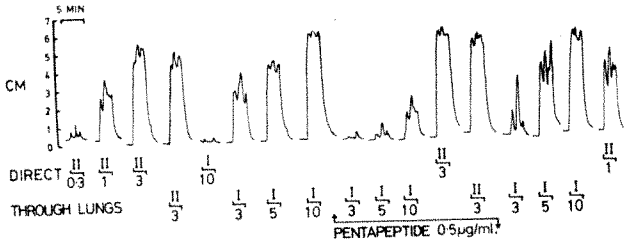

Fig. 1. The isolated lungs of a guinea-pig were perfused through the pulmonary artery with Krebs solution at 10 ml./min. The effluent superfused a rat colon, the contractions of which are shown. A I (I) or A II (II) was infused for 3 min into the Krebs solution to give the concentrations shown (ng/ml.). The sensitivity of the colon to A II (0·3–3 ng/ml.) was demonstrated by direct infusions into the pulmonary effluent. When A II was given into the pulmonary circulation (through lungs), there was only a slight reduction in size of contraction. A I (10 ng/ml.) given directly to the rat colon had no effect but caused graded contractions of the colon when infused (3, 5 and 10 ng/ml.) through the lungs. The conversion to A II represented about 50 per cent. When SQ 20,475 (pentapeptide, 0·5 μg/ml.) was infused through the lungs, the conversion of A I to A II was greatly reduced, but the effects of A II were unchanged. Conversion of A I in the lung recovered when the infusion of SQ 20,475 was stopped. Except for the first and last contractions, the trace was continuous but 3 to 5 min of the record between infusions has been removed to condense the figure. Vertical scale shows movement of pen recorder in centimetres with a ×4 magnification of contraction. The time scale was 5 min.

pentapeptide there was neither reduction in the direct effects of A II on the rat colon nor change in the removal of A II by the lungs. The generation of A II on passage of A I through the lungs returned when the infusion of inhibitor was stopped.

In four similar experiments different concentrations of the pentapeptide were used (0·1, 0·3, 0·5, 1·0 and 3 μg/ml.). There was a linear relationship between the degree of inhibition of converting enzyme and log concentration of inhibitor. SQ 20,475 gave 50 per cent inhibition of formation of A II at 0·15 μg/ml. and 100 per cent at 3 μg/ml. Thus the synthetic pentapeptide is a much more potent inhibitor of converting enzyme than the crude extract of snake venom which gave only partial inhibition[5] of the lung enzyme at 5 μg/ml.

Antagonism of Contractile Effects of A I

We next used the synthetic pentapeptide to find whether isolated arterial tissue contained converting enzyme activity. Arteries were removed from rats, rabbits and cats killed by a blow on the head, and from cats and dogs anaesthetized with pentobarbitone sodium and bled. The arteries were cut spirally into strips and superfused at 10 ml./min with Krebs solution at 37° C. The load applied to the strips was 2–4 g depending on their thickness (Table 1).

Both A I (100–1,000 ng/ml.) and A II (3–300 ng/ml.) contracted the arterial strips except those from cat renal arteries which were insensitive. The inhibitor of converting enzyme always reduced the contractions produced by A I without affecting those produced by A II. Fig. 2 shows this effect on strips of pulmonary artery (upper record) and thoracic aorta (lower record) from the same rabbit. Before adding SQ 20,475 the ratio of A I to A II to give equal activity was about 4 : 1 on the pulmonary artery and 20 : 1 on the aorta. In the presence of the pentapeptide (1 μg/ml.) the contractions induced by A I (400 ng) were substantially reduced, giving a new ratio of A I to A II of about 30 : 1 on the pulmonary artery and 65 : 1 on the aorta. After infusion of inhibitor was stopped the size of the contractions produced by A I increased again. This selective reduction in activity of A I strongly suggested that some of the activity of A I was due to its conversion to A II within the arterial strip itself. Furthermore, the conversion was much higher in the pulmonary artery than in the aorta.

The amount of intramural conversion was calculated as follows. The contraction of the pulmonary artery induced by A I at 400 ng/ml. was equivalent to A II at

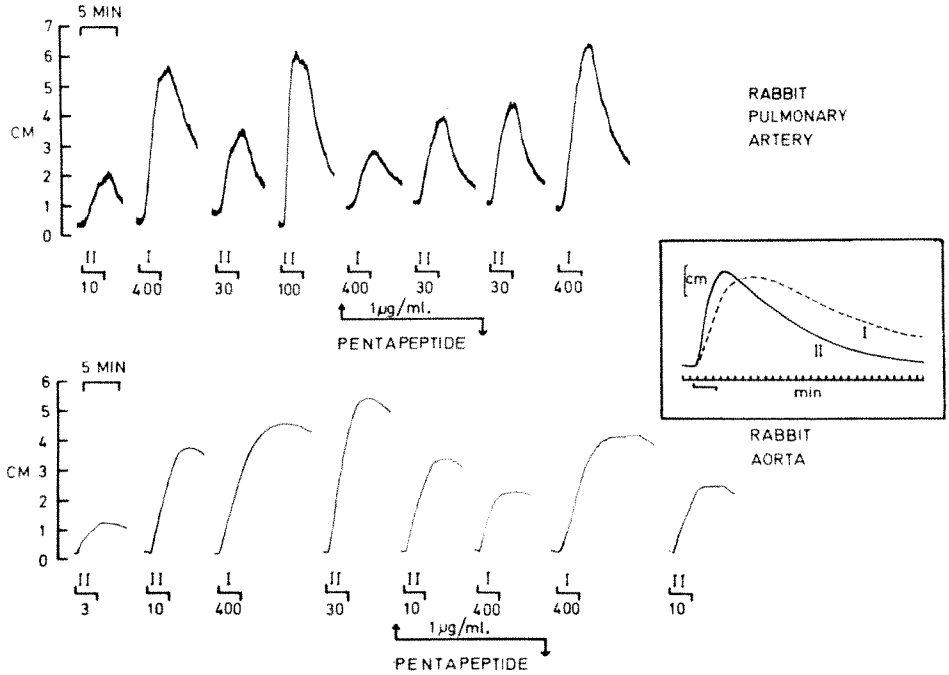

Fig. 2. The tracings show contractions of isolated strips of pulmonary artery (top) and thoracic aorta (bottom) from one rabbit. On the pulmonary artery an infusion for 3 min of A I (I, 400 ng/ml.) gave a contraction slightly less than that produced by A II (II, 100 ng/ml.). In the presence of the pentapeptide inhibitor (pentapeptide, 1 μg/ml.), the contractor activity of A I was selectively reduced. Similar results are shown for the thoracic aorta, except that in this preparation A I showed less activity (400 ng A I = 20 ng A II). Vertical scale in centimetres of pen movement (cm) ×15 (top) and ×10 (bottom) magnification of contraction. Time between infusions was 30 to 45 min. The time scale was 5 min. The inset shows the time course of contractions of a strip of rabbit aorta produced by A I (- - -) and A II (———). The vertical scale is centimetres of pen movement, with a ×10 magnification of contraction. The time scale is in 1 min divisions.

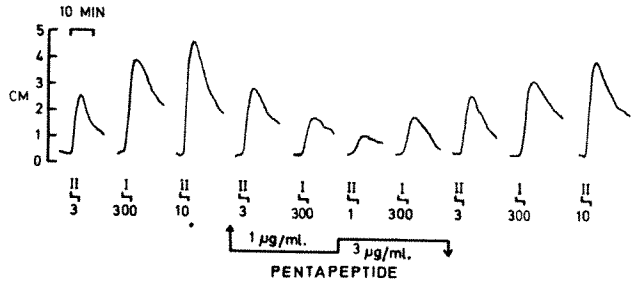

Fig. 3. This tracing shows contractions of an isolated strip of renal artery from a rabbit produced by A I (I, 300 ng/ml.) and A II (II, 1, 3 and 10 ng/ml.). Before the converting enzyme inhibitor, A I (300 ng/ml.) was equivalent to A II at about 6 ng/ml. When the inhibitor was infused (1 μg/ml.), the effects of A I at 300 ng/ml. were reduced, to become equivalent to A II at 2 ng/ml. No further reduction was achieved by increasing the concentration of inhibitor to 3 μg/ml. The vertical scale shows centimetres (cm) of movement of the pen recorder, with a ×20 magnification of contraction. The time scale is 10 min.

100 ng/ml. before inhibition and to A II at 10 ng/ml. during inhibition (Fig. 2, top). The reduction in activity was therefore equivalent to A II at 90 ng/ml. Assuming similar diffusion rates and distribution for A I and A II in the arterial strip, the concentration of A II reaching receptor sites during application of A I was equivalent to a conversion of 90 × 100/400 or 22·5 per cent within the tissue. This does not imply that 22·5 per cent of all the A I in the superfusion fluid was converted to A II, for the amount diffusing into the tissue can be only a minute fraction of the total dose applied.

When this calculation was applied to the experiment of Fig. 2, the conversion was 22·5 per cent in the pulmonary artery but only 4 per cent in the aorta. For more accurate estimates of conversion, taking into account the different molecular weights of A I (1,297) and A II (1,032), equipotent molar ratios were used (see later). These increased the conversion figure by about one fifth (27·5 per cent in the pulmonary artery and 4·9 per cent in the aorta).

In both vascular strips, A I produced a delayed onset and a slower decline of contraction than A II (see inset on Fig. 2). The fact that contractions induced by a 3 min infusion of A I sometimes took 7 to 9 min to reach a maximum suggested that A II continued to be formed within the tissue even after A I was no longer present in the superfusion fluid.

Another possible interpretation of the selective reduction of the activity of A I by SQ 20,475 is that the two angiotensins act on separate receptors and that the pentapeptide specifically blocks those for A I. This interpretation was rejected because cross tachyphylaxis showed that A I and A II acted on the same population of receptors. Contractions of a rabbit pulmonary artery were produced by noradrenaline, A I and A II. Repeated infusions of A II at 10 to 12 min intervals progressively desensitized the artery to A II. When the effects had almost disappeared, A I also had virtually no effect, whereas noradrenaline produced a greater response than before. In other experiments contractions produced by A II were selectively blocked when A I was used for desensitization. Similar results were obtained in strips of cat pulmonary artery and rabbit renal artery. When there are no specific antagonists, cross tachyphylaxis is good evidence for two substances acting on the same population of receptors[22]. Thus the specific inhibition of the activity of A I brought about by the pentapeptide SQ 20,475 must have been due to inhibition of conversion of A I to A II within the arterial strip.

Although SQ 20,475 reduced the contractions produced by A I, it never abolished them. For instance, in an isolated strip of renal artery from the rabbit (Fig. 3), A I (300 ng/ml.) produced a contraction equivalent to A II at 6 ng/ml. In the presence of the pentapeptide (1 μg/ml.) the contraction produced by A I was clearly reduced (A I at 300 ng/ml. now equivalent to A II at 2 ng/ml.). Increasing concentration of the inhibitor to 3 μg/ml., however, did not further reduce the contraction induced by A I (300 ng/ml.), showing that the effect of the pentapeptide was maximal at the lower concentration. Thus although the intramural conversion was only 1·5 per cent, about two-thirds of the total activity of A I on the rabbit renal artery in Fig. 3 was due to formation of A II; the remaining third was due to some other action of A I.

The maximum inhibition by SQ 20,475 (1–4 μg/ml.) of the effects of A I varied from artery to artery. Table 1 shows the relative potencies of A I and A II (±s.e. of

The mean equipotent molar ratios for A I and A II are shown before and during inhibition of converting enzyme by supramaximal concentrations (1–4 μg/ml.) of SQ 20,475. A low ratio means a high activity for A I. The weight on the lever is shown in g. n = Number of experiments. The standard (s.e.) of the mean is shown, except when n = 2, where the range is given. The last column shows the degree of tachyphylaxis to the effects of A I and A II (see text).

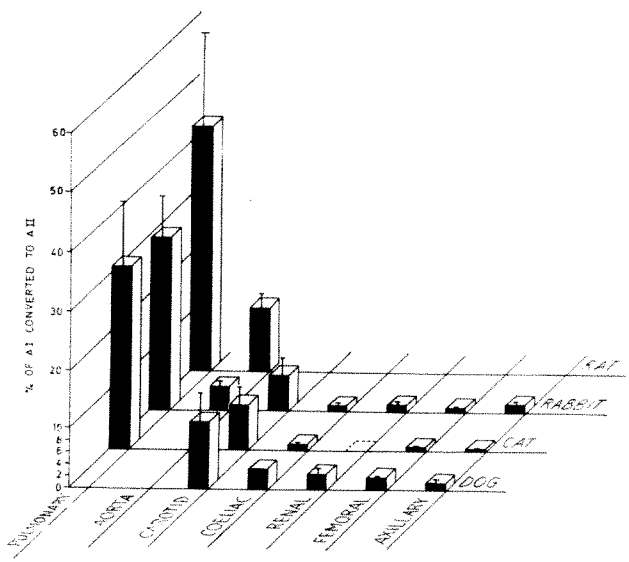

Fig. 4. The diagram illustrates the differences in converting enzyme activity shown by arterial strips from rat, rabbit, cat and dog. The activity is calculated from individual values, the means of which are shown in Table 1. The vertical lines at the top of the columns show either the s.e. or the range when n = 2 (see Table 1). Pulmonary arteries showed the highest activity, then rat aorta and then the carotid arteries. Coeliac, renal, femoral and axillary arteries had little or no activity. The cat renal artery did not contract to the angiotensins.

mean) before and during infusion of inhibitor. The relative potencies are expressed as the number of moles of A I equivalent to 1 mole of A II. Thus an "equipotent molar ratio" of 100 means that to produce the same contraction, one hundred molecules of A I were needed for each molecule of A II. The differences between the equipotent molar ratios before and during the infusion of SQ 20,475 were used to calculate, by the method described earlier, the amount of intramural conversion in each strip (Fig. 4).

Cat, rabbit and rat pulmonary arteries showed by far the greatest conversion (30–42 per cent). Dog pulmonary artery and dog and cat aorta were too thick to use. The aorta of the rat (10 per cent) and carotid arteries of the cat (8 per cent), dog (11 per cent) and rabbit (6 per cent) had relatively high converting enzyme activities. All the other arteries showed much less conversion (0·3–4 per cent).

The high intramural conversion in pulmonary arterial strips is an interesting corollary of the high conversion in blood-perfused[3,4] or saline-perfused[5] lungs. Converting enzyme might therefore be located in the vascular tissue; if it were present in all vessels down to the smallest pulmonary arterioles, the enormous surface area to which A I was exposed would explain its rapid conversion in the pulmonary circulation.

There was minimal conversion in renal, femoral and axillary arteries. It was in renal and femoral vascular beds that Ng and J. R. V.[3,4] were unable to detect conversion of A I to A II *in vivo*, although recently it has been suggested[23], on the basis of radioimmunoassays, that after massive doses of A I in the dog renal artery, about 8 per cent of the total immunoreactivity in the renal vein is A II. The significance of this figure is uncertain, for less than 30 per cent of the immunoreactive material in venous blood is in the form of A II (ref. 24). There was no striking variation in converting enzyme activity between species. There were some differences in the sensitivity of different arteries to A II. Whereas cat renal artery was insensitive and dog renal artery was relatively insensitive, femoral and axillary arteries were the most sensitive (Table 1). Thus the more peripheral arteries had greatest sensitivity to A II, but the least amount of converting enzyme. This suggests that, *in vivo*, the A II is delivered to these arteries rather than being formed in the walls.

Some arteries showed a gradual decline in response to repeated doses of A I or A II. With intervals of 30 min between infusions, tachyphylaxis was least evident in aortas, femoral and axillary arteries (graded 0 in Table 1) and most evident (+ +) in cat pulmonary, rabbit carotid, and rabbit and dog coeliac arteries. Tachyphylaxis occurred with all arteries when the interval between infusions was shorter (10 min).

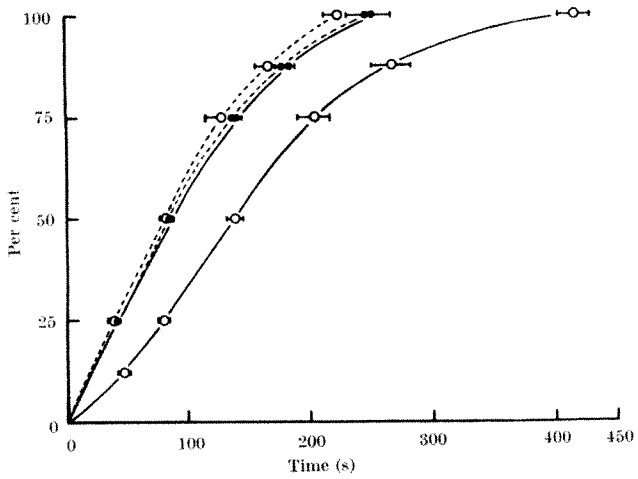

Fig. 5. The rates of development of contraction of strips of rabbit aortas ($n = 4$) are shown plotted against time in seconds. The closed circles are for A II and the open circles for A I. Before the converting enzyme inhibition (solid lines) the rate of contraction for A I was slower than that for A II. With the inhibitor present (dotted lines) there was no distinction in rates. To obtain the graphs, the time was measured for each contraction to reach 12·5, 25, 50, 75, 87·5 and 100 per cent of the final contraction height. The bars show the standard errors of the means.

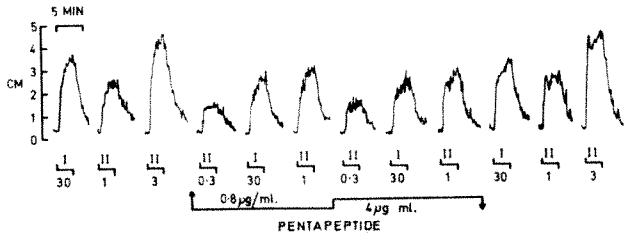

Fig. 6. The tracing shows the contractions of a rat colon superfused with Krebs solution at 10 ml./min. Before inhibitor, A I (I, 30) at 30 ng/ml. was equivalent to A II at 2 ng/ml. The inhibitor (pentapeptide 0·8 μg/ml.) selectively reduced the contraction induced by A I so that 30 ng/ml. was now equivalent to A II at about 0·8 ng/ml. Increasing the concentration of inhibitor to 4 μg/ml. did not further reduce the effects of A I. The vertical scale is in centimetres (cm), with ×4 magnification of contractions. The time scale is 5 min.

Residual Responses to Angiotensin I

In arterial strips, even with high concentrations of converting enzyme inhibitor present (Fig. 3), A I still produced small contractions. These could not have been due to contamination of the A I by a small amount of A II, because the residual activity of A I was equivalent to differing amounts of A II on different arteries (Table 1). These residual effects of A I might have been due to formation of A II by an enzyme not inhibited by the pentapeptide. This possibility has not yet been excluded. Our results suggest, however, that a more likely explanation is that A I has a feeble direct action (0·8–4 per cent) on A II receptors. First, on tissues such as pulmonary artery and aorta the rate of contraction induced by A I was slower than that produced by A II without the inhibitor but identical with the inhibitor present, as shown for rabbit aorta in Fig. 5. Rates of contraction are plotted (as a percentage of the contraction attained) for responses produced by A I and A II. The rate of contraction produced by A I was substantially slower than for A II, suggesting slow conversion of A I to A II within the vessel wall. When converting enzyme was inhibited, however, the rate of contraction induced by A I was as fast as that induced by A II, suggesting a direct action of A I and not one relying on an intermediate enzymic step. Similar effects were seen in pulmonary arteries. Further supporting evidence was found on the cat axillary artery, which has little or no converting enzyme activity; rates of contraction for A I and A II were similar without the inhibitor being present.

Our evidence suggests that the residual effects of A I are due to a direct but weak (0·8–4 per cent) action on A II receptors. In this context, it is interesting that in radioimmunoassays[25–27] A I reacts with the antibodies for A II to a similar extent (1–5 per cent). Such antibodies can be regarded as a form of receptor for A II.

Converting Enzyme in other Preparations

The contractile effects of A I on other isolated smooth muscle preparations were also reduced by the converting enzyme inhibitor. Fig. 6 shows this in an isolated ascending colon of the rat. A I at 30 ng/ml. caused a contraction of the colon approximately equivalent in size to one produced by A II at 2 ng/ml. (molar ratio A I : A II = 12:1). During infusion of SQ 20,475 (0·8 μg/ml.) the contraction induced by A I at 30 ng/ml. was reduced (molar ratio of A I : A II = 30:1). As in vascular tissue, contractions of the rat colon produced by A I could not be abolished by the pentapeptide. Thus increasing the dose of inhibitor to 4 μg/ml. had no further effect. Five minutes after infusion of pentapeptide was stopped the contraction produced by A I (30 ng/ml.) returned to near its original size. These results showed that, as in vascular tissue, part but not all of the response of the rat colon produced

Table 2. CONVERTING ENZYME ACTIVITY OF RAT NON-VASCULAR SMOOTH MUSCLE

Details as in Table 1. The last column shows the calculated intramural conversion of A I to A II.

by A I was due to its conversion to A II within the isolated tissue itself. Results similar to those for the rat colon were obtained with rat ileum and rat uterus, but the amount of converting enzyme activity was different in the three tissues (Table 2).

It is difficult to compare our results on rat isolated organs with those with rat tissue homogenates. The converting enzyme activity of macerated tissues, as measured by Huggins and Thampi[7], is different from that measured by Roth, Weitzman and Piquilloud[10]. Like Huggins and Thampi, we found low activity in the rat uterus, but we also found relatively high activity in rat aorta, whereas Huggins and Thampi found none. Furthermore, we found rat aorta to be higher in activity than ileum, whereas Huggins and Thampi found ileum to contain as much activity as lung tissue. These results emphasize again that enzyme activity measured in macerated tissues may not correspond to that measured in intact tissues.

This is the first time that the direct and indirect effects of A I on smooth muscle have been distinguished. The converting enzyme content of many isolated smooth muscle preparations is sufficient to contribute to the contractor action of A I by the intramural generation of A II. Such intramural generation of A II probably explains the high activities[12,13] of A I relative to A II, for when it is abolished, A I has a residual direct action of about 1–4 per cent of that of A II.

How important physiologically is the intramural generation of A II by converting enzyme in vascular tissue? First, the slowness of the intramural conversion must be emphasized. Whereas A I is almost completely converted to A II in the 2 to 5 s that it takes to traverse the pulmonary vascular bed, responses due to intramural conversion in arterial tissue *in vitro* take 4 to 8 min to develop. Unless the intramural conversion is much faster *in vivo*, it cannot contribute significantly to the effects of intravenous injections of A I. Similarly, when renin is present in the bloodstream, the lungs are likely to be the only important site for formation of circulating A II.

Any physiological importance of intramural conversion may be associated with a local role of the renin–angiotensin system within the vessel wall. A renin-like enzyme has been extracted from vascular tissue[28,29]. If this enzyme is effective *in situ* the juxtaposition of converting enzyme might, through the intramural generation of A II, contribute to the local control of vascular tone.

Calcium Induced Release of Calcium from the Sarcoplasmic Reticulum of Skinned Skeletal Muscle Fibres

The repeated contractions which can be observed in skinned fibres in appropriate concentrations of caffeine, Ca^{2+} and chelating agent suggest that calcium release is a regenerative process in which calcium itself causes the release of calcium from the reticulum.

It is now generally accepted[1] that at the final stage of excitation–contraction coupling calcium ions are released from the sarcoplasmic reticulum into the sarcoplasm, and Ca^{2+} in turn activates the contractile protein system. We have now further investigated the mechanism of the release of calcium from the sarcoplasmic reticulum using Natori's skinned fibre[2]. Although originally Natori's fibres were prepared and used under a mineral oil, the skinned fibres can also be kept in the relaxed state in an aqueous solution if the latter contains sufficient MgATP and GEDTA (glycolether diaminetetraacetic acid, or EGTA)[1,3]. With this preparation Ca^{2+} can be released easily and repeatedly from or reloaded on to the sarcoplasmic reticulum with the aid of a Ca^{2+}-releasing drug, caffeine[4]. In this way it was found that the free sarcoplasmic calcium itself induced the release of Ca^{2+} from the sarcoplasmic reticulum[5,6].

Living single twitch fibres were isolated from the semi-

tendinosus or iliofibularis muscle of the frog, *Rana japonica*; and all or part of the sarcolemma, together with underlying myofibrils, was removed in a K_2SO_4–Ringer solution containing 4 mM MgATP and 4 mM GEDTA. The skinned fibres thus obtained were set up in a trough through which a solution could be perfused rapidly. The two ends of the skinned fibres (1·5–3 mm long) were fixed between pieces of 'Scotch' tape and isometric tension was recorded with a mechanoelectronic transducer (RCA 5734 or Toshiba 5734 A). The normal medium consisted of 22 mM K_2SO_4, 20 mM Tris-maleate buffer (*p*H 6·8), 4 mM ATP, 4 mM $MgSO_4$, 96 mM sucrose and 2 mM GEDTA with or without a specified amount of $CaSO_4$. Experiments were usually conducted at 4° C by perfusing ice-cold water below the glass base of the trough.

When caffeine was applied to skinned fibres in appropriate conditions, it induced contraction (Fig. 1*a*). Weber and Herz[4] have clearly shown that the caffeine-induced contraction was the consequence of the release of calcium from the sarcoplasmic reticulum by the drug. This was certainly the case in skinned fibres, and the following experiments seem fully to confirm this mechanism of action of caffeine. First, purified phospholipase C, which is known to destroy the ability of the isolated sarcoplasmic reticulum (the relaxing factor) to induce relaxation[7] and to accumulate Ca^{2+} (ref. 8), abolished caffeine-induced contraction of the skinned fibres, whereas the contractile ability of the fibre was largely retained (Fig. 1b_1 and b_2). Second, the concentration of free Ca^{2+} in and around the skinned fibres was measured with a Ca^{2+}-binding dye murexide[9], and shown to increase during caffeine-induced contraction.

If the mechanism of caffeine-induced contraction is really as we have now described, the contractile response should be modified by the concentration of GEDTA in the medium. This was found to be the case. When the concentration of GEDTA was as high as 8 mM, 5 mM caffeine, for example, was never able to induce contraction. In the presence of 2 mM GEDTA, skinned fibres usually responded to this concentration of caffeine with a transient contraction, but this was a single response and it never recurred even if the drug was persistently present or re-applied after having been washed away (Fig. 1*a*). In the medium containing a low concentration of GEDTA (for example, 0·05 mM), smaller concentrations of caffeine were able to induce contraction of the skinned fibres. This was also transient but spontaneously recurred repeatedly in the continued presence of the drug (Fig. 1*c*, *d*). This behaviour of skinned fibres can be explained in part as follows. In the presence of 2 mM GEDTA, (1) most of the released Ca^{2+} eventually became bound to GEDTA molecules, and (2) because the concentration of free Ca^{2+} in the medium was very low (about 10^{-8} M) the reticulum of the skinned fibre could not take up enough Ca^{2+} again. In agreement with this view, if the fibre thus treated was immersed in a medium containing a higher concentration of free Ca^{2+} for a certain period, the responsiveness of the fibre to caffeine in the presence of 2 mM GEDTA was restored. As expected from the time course of re-uptake of Ca^{2+} by the reticulum, the degree of restoration was a function of the concentration of free Ca^{2+} and the time of immersion (Fig. 2). In the case of 0·05 mM GEDTA, the free Ca^{2+} concentration became about 5×10^{-7} M because of contaminating Ca^{2+} so that the reticulum could again take up Ca^{2+} (see Fig. 2), a process which constitutes the basis of the repeated release of Ca^{2+} by caffeine.

This discussion is still not a complete explanation of the repeated contraction we have observed. It was noted that the peak tension during the repeated contrac-

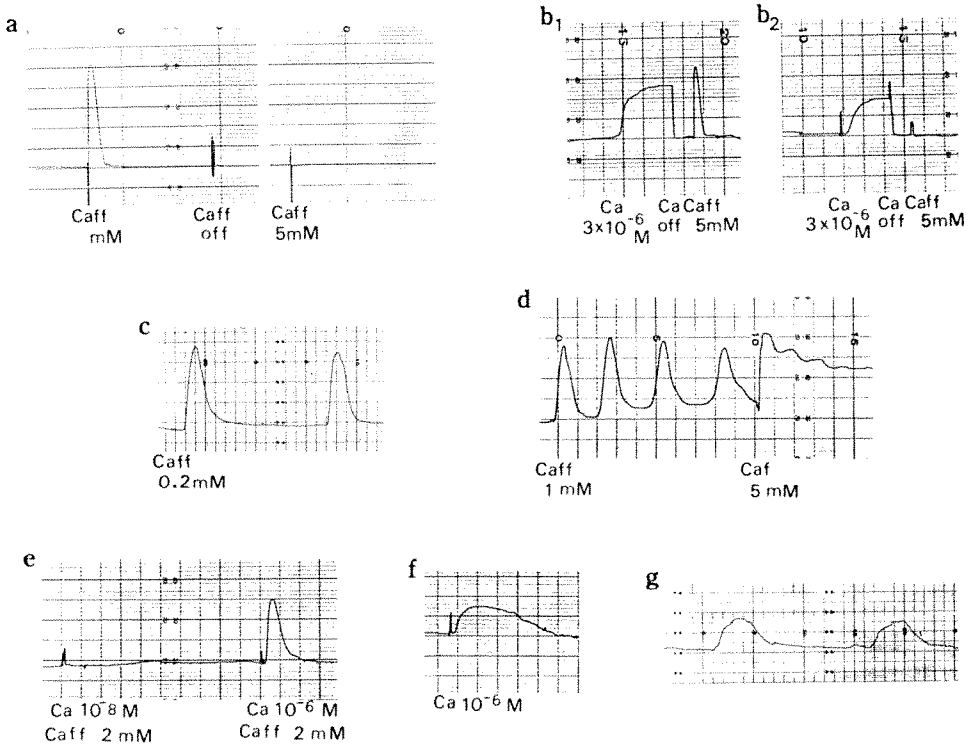

Fig. 1. Contractions of skinned fibres as a result of the release of calcium from the sarcoplasmic reticulum induced by various means. The experimental conditions were as described in the text except for the concentrations of GEDTA and Ca^{2+} and some additions. *a*, Transient contraction induced by 5 mM caffeine. GEDTA, 2 mM ($Ca^{2+} \simeq 10^{-8}$ M). Note that there was only a single response. *b*, The effect of phospholipase on caffeine-induced contraction. Between b_1 and b_2, the skinned fibre was treated for 30 min at room temperature with 2 mg/ml. phospholipase C, which was prepared from *Clostridium perfringens* and purified by column chromatography on DEAE-Sephadex G 50'. GEDTA, 2 mM. *c* and *d*, Oscillatory contractions induced by caffeine. GEDTA, 50 μM ($Ca^{2+} \simeq 5 \times 10^{-7}$ M). *e*, Contraction induced by a subthreshold concentration of Ca^{2+} in the presence of 2 mM caffeine. GEDTA, 2 mM. *f*, Contraction induced by a subthreshold concentration of Ca^{2+} in the absence of any drugs. GEDTA, 150 μM. *g*, Spontaneous oscillatory contractions. GEDTA, 25 μM ($Ca^{2+} \simeq 1 \times 10^{-6}$ M). Time: 24 s per division. Tension: 7 mg per large division.

tions of low frequency induced by caffeine was usually more than 80 per cent of the maximum tension that could be developed by the same fibre with the application of sufficient Ca^{2+}. This suggests that the characteristics of calcium release from the sarcoplasmic reticulum followed an essentially all-or-none pattern (albeit not genuine) along the entire length of the fibre. Indeed, microscopic observation revealed that sometimes during the rising phase of tension, a region of about 20–30 μm in which sarcomeres were highly shortened moved slowly from one end of the fibre to the other. If part of the effect of calcium release or its underlying processes were the induction of further release of calcium, a positive feedback loop would be formed and release of calcium would be according to an all-or-none pattern. We show later that free calcium causes the further release of calcium from the reticulum.

As shown in Fig. 1*e*, 10^{-6} M free Ca^{2+}, which by itself was usually below the threshold for contraction[1], evoked a transient contraction in the presence of a low concentration of caffeine (0·5–2 mM). It might be thought that 10^{-6} M Ca^{2+} would merely have brought the medium nearer to the threshold for contraction so that the amount of Ca^{2+} released by the low concentration of caffeine, which had been ineffective in inducing contraction in the presence of 2 mM GEDTA, could become effective. There are, however, a number of reasons why this is not possible, as the following experiments illustrate. The amount of calcium that remained in the reticulum after caffeine treatment in certain conditions was measured by applying to the fibre a higher concentration of caffeine, which released the remaining Ca^{2+}. The more Ca^{2+} was released by the first caffeine treatment, the smaller was the contraction in the second treatment. Fig. 3 demonstrates that more Ca^{2+} was released in the presence of 10^{-6} M free Ca^{2+} than with 10^{-8} M free Ca^{2+}. Thus free Ca^{2+} itself has an action on the reticulum which promotes the release of calcium. The effect was also observed in the absence of any drugs (Fig. 1*f*), indicating that it is an intrinsic property of the sarcoplasmic reticulum. This may also be reflected in the oscillatory contractions which occurred spontaneously in the absence of any drug (Fig. 1*g*).

Strontium ions showed a similar calcium-releasing action, although the effective concentration was about fifty times greater than for calcium. Free Mg^{2+} inhibited the release of Ca^{2+} from the reticulum, as was previously known[10].

The calcium-releasing action of Ca^{2+} which we have demonstrated may be the principal mechanism of the all-or-none type of calcium release from the sarcoplasmic

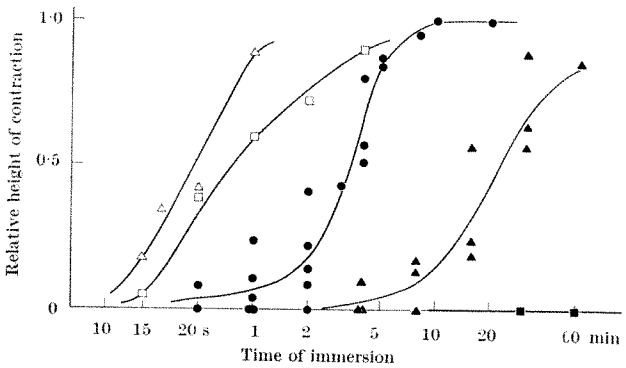

Fig. 2. Time course of restoration of the response of skinned fibres to caffeine for various concentrations of free Ca^{2+}: △—△, 10^{-5} M; □—□, 3×10^{-6} M; ●—●, 10^{-6} M; ▲—▲, 3×10^{-7} M; ■—■, 10^{-7} M. The experimental conditions were as described in the text. After calcium had been loaded on the sarcoplasmic reticulum of skinned fibres in a medium containing a certain concentration of free Ca^{2+} for a certain period, it was released by 5 mM caffeine in the presence of 2 mM GEDTA and the resulting transient contraction was recorded. Treatment with 10^{-6} M Ca^{2+} for 10 min was taken as standard, and the relative values of peak isometric tension in these contractions are plotted.

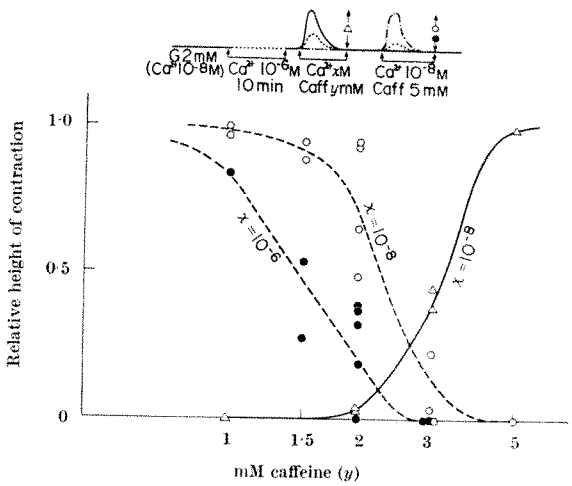

Fig. 3. Caffeine-induced release of calcium from the sarcoplasmic reticulum of skinned fibres and the effect of free Ca^{2+}. The experimental conditions were as described in the text. After calcium had been loaded on the reticulum by treating skinned fibres with 10^{-6} M Ca^{2+} for 10 min, caffeine was applied to the fibres with various concentrations of free Ca^{2+} and the peak tension of the resulting contraction was plotted (continuous line). The tension produced by 5 mM caffeine in the presence of 2 mM GEDTA (G) ($Ca^{2+}\simeq10^{-8}$ M) was taken as standard. The calcium remaining in the reticulum after this treatment was then released in controlled conditions, that is, with 5 mM caffeine in the presence of 2 mM GEDTA, and the peak tension of the resulting contraction was plotted as a function of the conditions of the first caffeine treatment (broken lines).

reticulum in the skinned fibre. It has not yet been possible to initiate contraction by other means, such as stretching the skinned fibre, or applying ADP or inorganic phosphate to the fibre.

It was recently demonstrated[11] that the physiological release of the activator of contraction occurs in a somewhat regenerative manner and this may be related to the well known sharp relationship between depolarization and tension in living muscle fibres. It is very probable that the Ca^{2+}-induced release of Ca^{2+} which we describe is the mechanism of the regenerative nature of the physiological contraction following depolarization. Adrian *et al.*[11] explained the regenerative nature of the release of the activator by assuming a kind of substrate inhibition in the re-uptake of the activator. But if we assume (as is reasonable) that the activator is Ca^{2+}, the rate of uptake of calcium by the reticulum in skinned fibres is never inhibited but is accelerated by increase in the concentration of Ca^{2+}, as indicated by experiments such as those illustrated in Fig. 2. A similar relationship is also obtained in the presence of caffeine. The rate of uptake of calcium by the isolated reticulum measured by Weber *et al.*[12] and Ogawa[13] also displayed monotonic dependence on the concentration of free Ca^{2+} in the medium. It therefore seems that the calcium induced release of calcium is a consequence of true activation of the release process, somehow produced by calcium itself.

We thank Professor S. Ebashi for advice, discussion and encouragement. This work was supported in part by the grants from the US Public Health Service, the Muscular Dystrophy Association of America and the Iatrochemical Foundation, Tokyo.

Lateral Inhibition between Orientation Detectors in the Human Visual System

by

Cambridge CB2 3EB

Experiment has shown that two lines of different orientation interact with each other so that they seem to be displaced from one another in orientation. This could be explained in terms of mutual inhibition between neighbouring columns in the visual cortex.

LATERAL inhibition is a very common property of sensory systems. Retinal ganglion cells receive antagonistic signals from an area of receptors surrounding the central zone of their receptive fields[1,2], and the same thing holds for somatosensory neurones with receptive fields on the skin[3,4]. Fibres in the auditory pathway also have inhibitory connexions with large areas of the basilar membrane adjacent to the region of their characteristic frequency[5,6].

Presumably lateral inhibition has important general functions. It has been pointed out, for example, that it sharpens up the positional information conveyed through a sensory neurone by strictly limiting the region of receptors that activate it[7,8]. Another important consequence, particularly in visual and somatosensory systems, is the elimination of spatial redundancy: any large stimulus that completely covers a receptive field will be relatively ineffective in exciting the neurone, because of the simultaneous inhibitory and excitatory signals. But the edge of a stimulus, falling on the skin or the retina, will be particularly exciting because it will cover only part of the inhibitory surround.

In the visual cortex of the cat and the monkey almost all the cells are selectively sensitive to the orientation of edges and lines in the visual field[9,10]. There is good reason to believe that there are orientation detectors in the human brain too[11–14] and now we present some psychophysical evidence that there is lateral inhibition between them.

Lateral Interaction in the Orientation Domain

Imagine that any orientation detector in the human visual cortex is excited by a relatively narrow range of orientations and is inhibited by a much broader band, with both the inhibitory and excitatory weighting functions being centred on the same optimal orientation. Then presentation of a single line would be expected to produce a distribution of activity among the population of orientation detectors. Those tuned to optimal orientations near that of the line would be excited; those tuned to rather different orientations would be inhibited. So the overall distribution of activity might look like one of the two individual functions shown in Fig. 1. An inhibitory process like this would, as Andrews[14] suggested, sharpen up the neural specification of the orientation of a single line. There are, however, serious consequences when another nearby line of a different orientation is simultaneously present.

Fig. 1 shows two hypothetical distributions of activity created by two individual lines of different orientation, and at the bottom of the diagram the two distributions are simply added together, assuming linear summation of inhibition and excitation. It is clear that the peaks of activity in this compound distribution are slightly shifted apart from the individual peaks produced by the single lines.

If the brain assesses the orientation of contours by inspecting this distribution and, say, identifying the most active neurones, then there should be distinct influences of one orientation on another. In fact, two lines forming an acute angle should appear to be shifted away from each other in orientation; the angle between them should seem to expand. This is true. Our explanation of this phenomenon in terms of lateral inhibition in the orientation domain should be contrasted with theories in which inhibition in the position domain is said to cause apparent "repulsion" of neighbouring parallel contours[8,15].

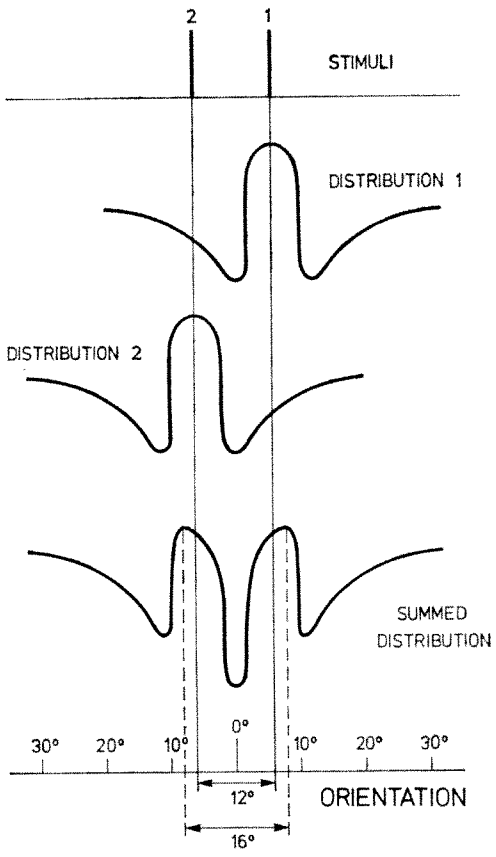

Fig. 1. This diagram represents, in a speculative way, the distributions of activity that might be set up in the orientation domain by two lines of different orientation. The abscissa of the figure is orientation, in degrees, as shown on the scale at the bottom. The two pulses at the top of the diagram represent the two stimulus lines, which differ in orientation by 12 degrees. Below them are the two profiles of activity that they would create individually in the population of orientation detectors. There is a broad peak of excitation among detectors tuned to orientations near that of the line and those further away from the line in orientation are inhibited. The bottom distribution shows what might happen if the two lines, forming an angle with each other, are shown simultaneously to the system. Addition of the individual profiles produces a compound distribution with the peaks of activity slightly displaced from each other.

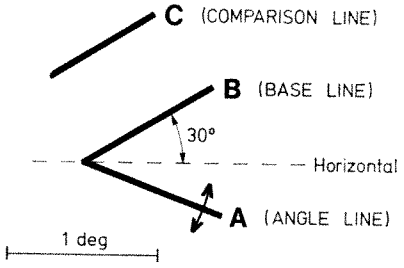

Fig. 2. The computer generated three bright lines on the face of the oscilloscope. The lines had a luminance of about 10 cd.m^{-2} and the dim background was about 0·1 cd.m^{-2}. Two of the lines, a "base line", *B*, and an "angle line", *A*, met at the centre of the screen to form an angle, so that they appeared to the subject like the hands of a clock. They were both 1·4 cm long so that they subtended 1 degree in length at the subject's eyes. Their width was about 2 min of arc. There was a similar "comparison line", *C*, 0·8 degrees long, with its centre on the normal through the middle of *B* and 0·6 degrees away from it. During all the experiments reported here *B* was fixed in the upper right quadrant of the screen at an angle of 30 degrees to the horizontal. Line *A* was rotated to form various angles with *B*.

Measuring the Phenomenon

An observer sat in a darkened room, 80 cm from an oscilloscope screen. A computer (Digital Lab-8) generated a pattern of bright, blue-white lines on the P-7 phosphor of this oscilloscope. The display took the form shown in Fig. 2 and described in the legend. The subject could alter the orientation of the "comparison line", *C*, by turning a knob that made it rotate about its centre. His task was to set *C* parallel to the "base line", *B*. Each time the knob was turned the display flickered slightly as the new commands were computed, but after a little practice this did not bother the subject.

We then tested the effect of the "angle line", *A*, on the apparent inclination of *B* as assessed by the setting of *C*. The subject bit on a dental impression to keep his head vertical and he was allowed to look wherever he liked within the display during the observations.

For the results shown in Fig. 3 the base line, *B*, was always set at 30 degrees anticlockwise from the horizontal, in the upper right quadrant of the screen. For the upper graph in Fig. 3, line *A* was set at different angles clockwise from *B*, up to 180 degrees, and line *C* was above *B*, as shown in the inset diagram. The subject made four pairs of settings of *C* for each value of the angle between *A* and *B*, in random order. At each setting the computer read the angle of *C*, in degrees, with respect to the orientation of *B*, anticlockwise being positive. For each value of *A* the mean of all eight settings was calculated along with its standard error.

The mean setting of *C* is plotted on the ordinate, zero being truly parallel to *B*, positive being anticlockwise error; negative, clockwise error. Results are shown for two subjects, with vertical bars representing one standard error on each side of the mean.

The whole experiment was repeated but with *A* rotated to different angles anticlockwise from *B* and with the comparison line, *C*, below *B*. The results are plotted in the lower graph of Fig. 3. It is evident that acute angles, particularly of the order of 10 degrees, appear to be very grossly expanded, each component orientation being displaced in orientation away from its partner. If both lines are equally displaced then the total enlargement of an angle of 10 degrees is about 4 degrees.

Now if the neural system for orientation detection were completely insensitive to position in the visual field, a line in the lower left quadrant should be indistinguishable to the system from its parallel in the upper right quadrant, and should have the same effect on *B*. So obtuse angles should appear to be contracted. The function should be symmetrical but inverted on each side of 90 degrees.

It is obvious from Fig. 3 that obtuse angles indeed seem contracted but the effect is not as great as that of acute angle expansion. The effect of an obtuse angle of 170 degrees in the upper graph of Fig. 3 is by no means as strong as the effect of an acute angle of 10 degrees in the lower one. It seems, then, as if the neural mechanism is somewhat, but not totally, specific for the position of the lines. This is only to be expected from the fact that there is considerable variation in the length and size of receptive fields even in the foveal projection area of the cortex[9,10]. A line of one orientation presented to different parts of the fovea will stimulate much the same, but not completely the same, group of neurones at each position.

We have illustrated results for just two subjects and at only one orientation of *B*, but we have confirmed the basic finding informally with several other subjects. We have also tried many other orientations of *B* and find roughly the same general effect. There is nothing dramatically special about angles with a horizontal or a vertical line as one of the component orientations. It is clear that an angle of 30 degrees in the upper graph of Fig. 3 (where line *A* is horizontal) and an angle of 30 degrees in the lower graph (where *A* is 30 degrees off-vertical) have similar magnitudes of effect on *B*, but in opposite directions, of course.

Orientation Detectors and Visual Illusions

Gibson[16] noticed this interaction between lines and described it in terms of "simultaneous contrast" between two orientations. He measured the influence of an off-vertical grating superimposed on a truly vertical line by rotating the line until it appeared vertical. In fact, Hering, von Helmholtz and Wundt had all concluded that acute angles must seem expanded because of the distortions that occur in certain of the geometric illusions. The Hering and Zöllner illusions, for example, in which lines seem to be twisted or bowed in the presence of other lines, could easily be explained in terms of angular distor-

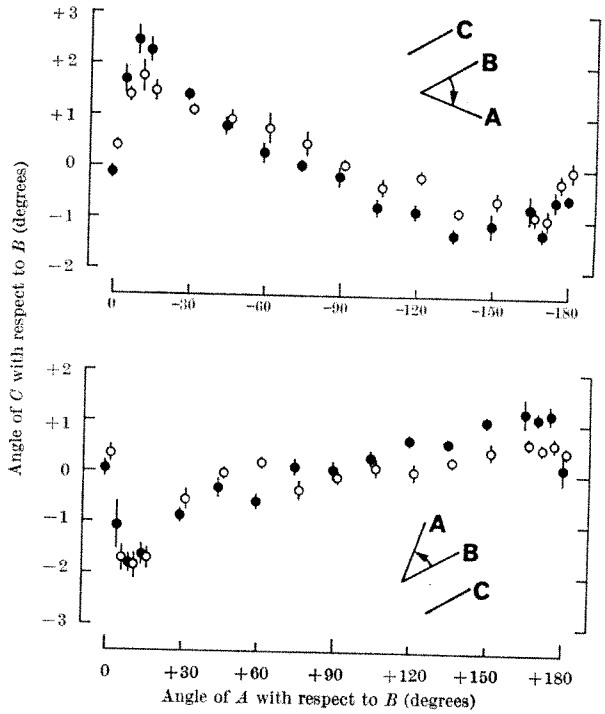

Fig. 3. The base line, *B*, angle line, *A*, and comparison line, *C*, were displayed as shown in the inset diagrams. *B* was always fixed at 30 degrees anticlockwise to the horizontal. For the upper graph, *C* was set above *B*, and *A* was rotated clockwise from *B* to form various angles with it. The abscissa is the angle of *A* measured from *B*, anticlockwise being positive. With the same sign convention the ordinate is the setting of *C* at which it appeared parallel to *B*. Each point is the mean of eight judgments, with vertical bars representing one standard error on each side of the mean. The data points for the two subjects have been slightly separated from each other horizontally to avoid overlap. The lower graph is much the same but in this case *C* was below *B*, and *A* was rotated anticlockwise to form various angles with *B*. ○, R.H.S.C.; ●, C.B.

tion. Jastrow[17] tried to measure this phenomenon by asking people to draw angles of particular sizes. Although he found big errors, there is, as Fisher[18] points out, a logical fallacy in this technique. Fisher himself asked subjects to estimate, in degrees, the size of angles shown to them. But there are obvious logical difficulties in that approach as well. We believe that our method, using a comparison line, overcomes the problem of reference to an internal image of verticality or a subjective scale of angle.

It is possible, of course, that the comparison line, C, is somewhat influenced by line A, and that we have therefore underestimated the phenomenon. This is something we must explore more closely in future experiments and we must certainly keep the possibility in mind when we attempt to predict the extent of geometric illusions from these basic data.

Inhibition or Adaptation?

It might seem that the results we obtain could be a product not of lateral inhibition but of "adaptation" or "satiation". As Sutherland[19] suggested, a reduction in the sensitivity of cortical neurones after prolonged stimulation could be responsible for such shifts in apparent orientation. Expansion of angles might be due to the same sort of adaptation process that is thought to cause the well known figural after-effects of orientation[16].

There are three reasons why we reject this hypothesis. First, we find angle expansion virtually unchanged if the subject makes his settings in 3 or 4 s, with long rest periods in between, implying a very fast build-up of the supposed adaptation. Second, because the observer generally glanced back and forth between B and C, recovery from adaptation must have been very fast to prevent C and B being equally influenced by A. These observations do not square with the long time-constants of known adaptation phenomena[11,12,16]. Finally, and perhaps most compelling, we have found that the effect of A on B is reduced by the addition of another line forming a small angle with A. "Disinhibition" of this type cannot be explained by any kind of adaptation.

In summary, we have found that two lines of different orientation interact with each other so that they seem displaced from one another in orientation. The effects could be explained in terms of mutual inhibition between neighbouring columns in the visual cortex, each of which contains cells tuned to one orientation. We must admit that, so far, there is no evidence that cortical units are inhibited by orientations away from their optimal, but we hope to test that hypothesis with neurophysiological experiments.

We are happy to acknowledge that Jeremiah Nelson of the Department of Psychology at the State University of New York, Stony Brook, is thinking along similar lines (personal communication and manuscript in preparation). We thank him for corresponding with us. One of us (C. B.) holds a research grant from the Medical Research Council.

New Stochastic Model for Geomagnetic Reversals

by

IAN K. CRAIN

Department of Geology,
School of General Studies,
Australian National University,

P. LOUISE CRAIN

Bureau of Mineral Resources,
Canberra, ACT

A non-stationary model for geomagnetic reversals is proposed. From the model, a mean length of all polarity intervals of 1·6 m.y. is predicted.

THE occasional reversal of the Earth's dipole magnetic field is apparently a random process. To a first approximation, the occurrence of reversals resembles a stationary Poisson process, which led Cox[1] to propose a stochastic model for this phenomenon. In his model, the Earth's dipole field was assumed to oscillate regularly with constant polarity, reversing only when "triggered" into the opposite sense by the effect of random (normally distributed) non-dipole components, having mean zero and fixed standard deviation. The model suggested, physically, a number of time-varying eccentric dipoles in the vicinity of the core–mantle interface.

This model adequately explains the reversal pattern for the most recent 10 m.y. It was apparent to Cox, even then, however, that the same model could not apply to the Permian, where reversals were known to be much less frequent[2]. This has now been verified in the Cretaceous as well[3], making this simple stationary model inadequate. The partial success of Cox's model has led us to suggest a non-stationary extension of his principle.

In searching for the exact nature of the non-stationarity, we discovered the long-period regularity reported in a previous article[4], in which significant polarity oscillations with periods of about 300 m.y. and 75 m.y. were noted. Subsequently, we have performed spectral analysis of Simpson's mixed measurements and obtained periods of about 150 m.y. and 40 m.y. We are thus faced with the apparent paradox of a random process which exhibits regularities. We therefore propose the following non-stationary model.

Cox[1] considered in detail many physical reasons for suggesting a stochastic model involving an interaction of a regularly fluctuating dipole field and a random non-dipole component; these arguments will not be repeated here. The Earth's field is idealized by a sinusoidal variation of the form

$$F_e = \delta[A + B(1 + \cos(2\pi t/P_e + \varphi_e))] \qquad (1)$$

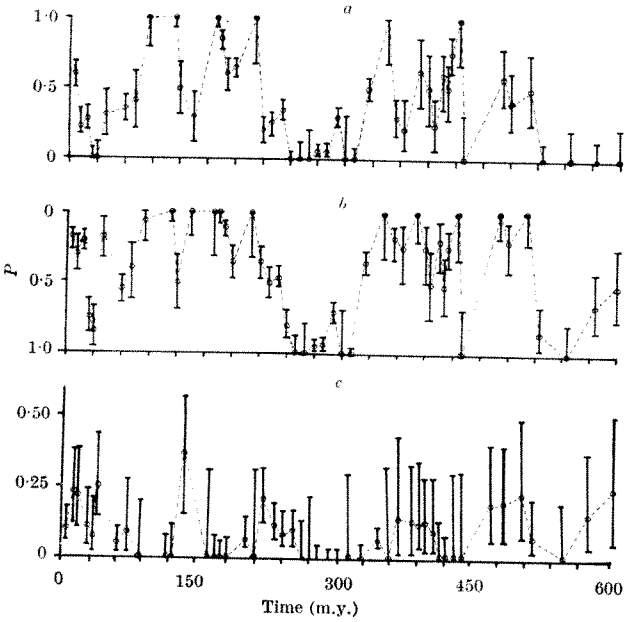

Fig. 1. Curves showing the proportion of normal (*a*), reversed (*b*), and mixed (*c*) palaeomagnetic measurements as compiled by Simpson. Approximate 95 per cent confidence limits are shown.

The minimum value, or bias of the field is A, the amplitude of the oscillation is B. The period and phase are denoted by P_e and φ_e respectively. The coefficient δ is either plus or minus one, depending on the polarity of the field; t denotes time.

The non-dipole or triggering field is a random variate from a normal distribution with mean given by

$$\mu = \alpha \cos(2\pi t/P_a + \varphi_a) \quad (2)$$

and standard deviation given by

$$\sigma = \beta|\cos(2\pi t(P_b + \varphi_b)| \quad (3)$$

The quantities α and β represent amplitudes, P_a and P_b periods and φ_a and φ_b phase angles of the oscillations. We introduce an additional parameter, C, a measure of the relative magnitude of the non-dipole field. Whenever at the moment of sampling, the following expression has negative sign, the field is reversed and the sign of δ is switched (that is, whenever the non-dipole component exceeds the dipole field in magnitude and is opposite in sign).

$$F_e[F_e + CN(\mu,\sigma)] \quad (4)$$

Where $N(\mu,\sigma)$ represents a random variate from a normal distribution with mean μ and standard deviation σ.

Several thousand realizations were generated by computer, over wide ranges of all the parameters. The random component was simulated by a series of discrete states generated from a normal distribution; from Cox's results, a 1,000 year spacing was used as a reasonable estimate of the growth and decay time of the non-dipole components. Obviously, we cannot reproduce the results of all the simulations here, but we will show the important results and summarize the effects of the various parameters.

A simulation for one full period (P_a) represents one individual of the total population of realizations of the model with a given set of parameters. For such an individual, curves of the proportion of normal polarity, P, reversal rate, RR, and the frequency of mixed measurements, M, can be plotted against time. A number of repetitions of the same experiment yield the mean time-variation of these factors. A mixed event was deemed to occur whenever the net effect of the dipole and random components was less than the bias level, A.

Fig. 1 shows the Earth's reversal history as compiled by Simpson[5], replotted on a linear time scale. Each point represents the proportion of the given polarity over approximately a 15 m.y. period. For comparison, polarity proportion curves produced by the model are also averaged over this period.

Fig. 2 shows the various mean behaviour curves for the "prime" model, that is, the model which gave the closest agreement with the known facts. The successful parameters are $A = 0{\cdot}1$, $B = 1{\cdot}0$, $\alpha = 1{\cdot}0$, $P_a = 300$ m.y., $\beta = 1{\cdot}0$, $P_b = 75$ m.y., $C = 0{\cdot}3$. Fig. 3 shows the curves for one typical individual realization of the model. Note the relatively large deviation of the individual from the mean, and the similarity in form between the model individual and the observed individual (Fig. 1).

Curves of mean reversal rate and maximum reversal rate as a function of various parameters are shown in Fig. 4. Predictably, the value of the bias, A, and the relative amplitude of the non-dipole component, C, are critically important factors. The period of the dipole oscillation, P_e, is unimportant if less than 2 m.y. Because of the extremely high ratio of P_a to P_e, the phase φ_e, is irrelevant. The amplitude of the dipole oscillation, B, also has little effect on the results. Cox[1] also gives reason for believing that the exact shape of the oscillation is unimportant.

The ratio of the amplitudes (α and β) of the random non-dipole oscillation affects the ratio of the primary and secondary peaks in the RR curves. Comparison of the computed curves with Fig. 1 puts limits on α/β as 0·5 to 2·0. We examined the effect of the periods P_a and P_b by spectral analysis. The model cannot resolve small differences in period, and to be discernibly different from the observed spectrum, the model parameters had to be outside the ranges 260 m.y. $< P_a <$ 380 m.y. and 65 m.y. $< P_b <$ 90 m.y.

The model predicts for periods of high reversal rate, such as the tertiary, a rate of about 7·5 per m.y., in good agreement with Harrison[6]. The predicted rate of 2·7 per m.y. for the last 80 m.y. agrees favourably with ocean floor spreading estimates[7]. The long-period behaviour is similar to the known pattern[4] and the polarity proportion curve of a typical individual has the same character as the observed curve (Fig. 1). The match of the mixed curve is only moderately good. There is some agreement

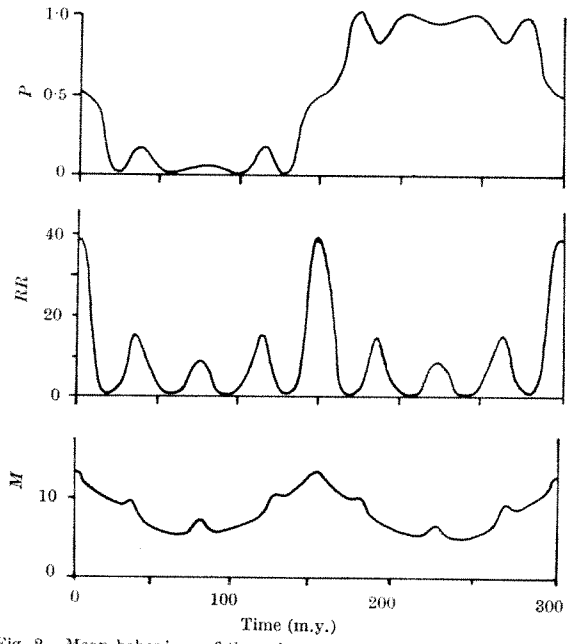

Fig. 2. Mean behaviour of the prime model. P = Polarity proportion, RR = reversal rate in reversals per m.y., M = mixed events. Scale of M curve is arbitrary.

between the reversal rate curve and the observed mixed curve, which suggests that a portion of these are caused by a number of reversals within a short time. A quasi-exponential distribution of interval length is obtained as observed by Cox[1]. A χ^2 test on the model produces a statistic of 35·62 (45 degrees of freedom), which is well below the critical region for rejection of the hypothesis (62·83).

Some physical interpretation of the parameters would certainly enhance the value of this stochastic model. The dipole oscillation portion is quite consistent with various physical models of self-excited dynamo behaviour, the susceptibility of which to triggering into a reversed state has been shown[8]. Associating a physical process with the random (but regularly fluctuating) component is difficult and must be speculative. The thermodynamics of the planet make an internal terrestrial source for such an oscillation unlikely. On physical grounds we reject Steiner's[9] hypothesis of an oscillating Earth's radius and contend that all major global processes are proceeding irreversibly on the time scale considered. The source must therefore be sought externally. The excitation medium is apparently polarized so that the mean direction of the random component alternates in sign with a long period of about 300 m.y., while becoming more variable about every 75 m.y. Our interpretation of this phenomenon is that it is correlated with the Earth's position in the galaxy, the rotational period of which is about 280 m.y.[9]. The excitation is apparently more uniform in the galactic plane, accounting for the change in variance corresponding to the vibration of the solar system perpendicular to the galactic plane with period 84 m.y.[10]. The galactic magnetic field is probably too small to be a direct cause (although only a small effect is required). Dauvillier[11] has suggested a possible solar–terrestrial interaction for magnetic reversals. Perhaps a ternary galactic–solar–terrestrial interaction should be proposed.

On the basis of the model we predict a mean length of all polarity intervals of 1·6 m.y., long intervals of constant polarity in the Silurian (normal) and Middle Cambrian (reversed), periods of frequent reversals in the Jurrassic, Carboniferous, Ordovician and Lower Cambrian, and that the palaeomagnetic history of other terrestrial

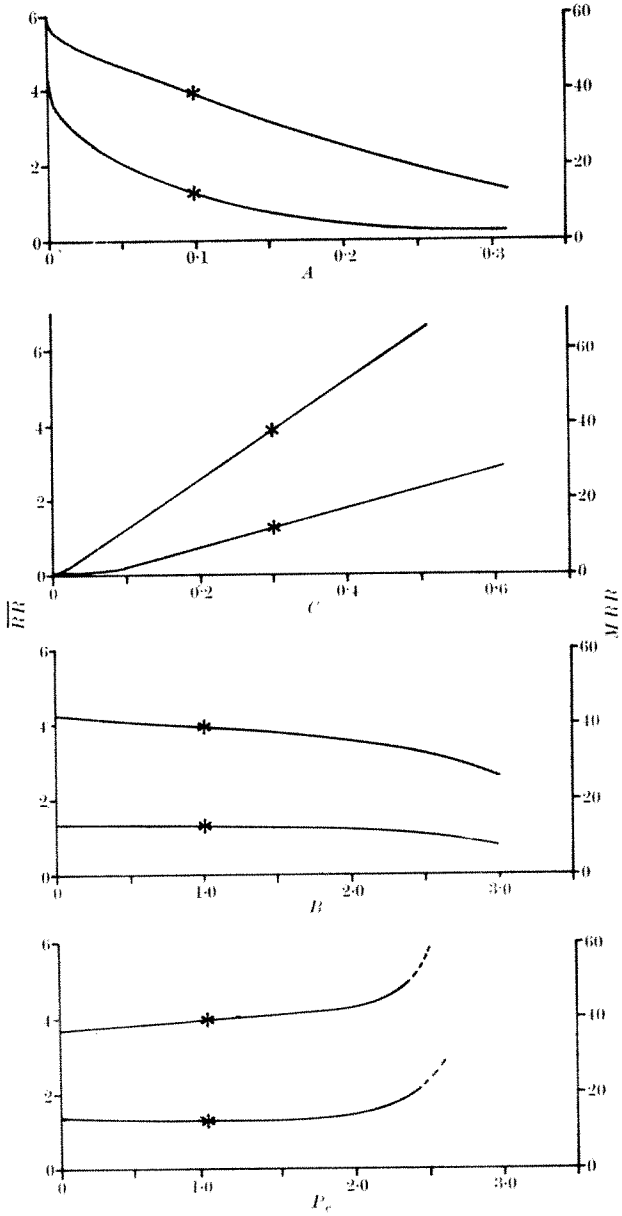

Fig. 4. The effect of varying the model parameters. $\overline{RR}$=Mean reversal rate, left-hand axis, lower curve; MRR=maximum reversal rate, right-hand axis, upper curve.

planets with Earth-like cores will show the same long-period behaviour.

Another implication is that magnetic anomaly patterns may be of limited use in delineating ocean-floor spreading which is older than Cainozoic. The search for older magnetic lineaments (in the north-west Pacific, for example) should be concentrated in ocean floor of Jurassic or Carboniferous age.

We thank Mr M. G. Plaut for assistance in the Fourier techniques, and Miss C. M. Botley for directing us to the work of Dauvillier.

Pulsar Nulling Phenomena

DURING an investigation of the short-term behaviour of the radiation coming from pulsars during strong bursts, several objects were found to exhibit pulse nulling phenomena. This was first noted on analogue records of the pulsar radiation intensity where the pen deflexions are a rough measure of the pulse energy. PSR's 0834+06, 1133+16, 1237+25 and 1929+10 were found suddenly to miss from one to ten pulses at various times, termed "nulls", during otherwise very strong and steady bursts. A null means that the pulse energy decreased by a factor of ten or more over one or two pulse periods and then increased just as sharply after the null. The nulls can be divided into two types according to their duration and their spacing. Type I nulls are the most prominent with a width between three and ten pulses and recur with spacings of about fifty pulses. Type II nulls have a width of only one or two pulses and recur with spacings of three to ten pulses. Pulse sequences from 1133+16 and 1237+25 and possibly 0834+06 contain the Type I nulls while sequences from all four objects contain Type II nulls. A quick look at the spacings of these nulls suggests that they may recur periodically and hence contribute to responses at characteristic periods in pulse energy fluctuation power spectra. This possibility has been reported indirectly by Sutton *et al.*[1] and Hesse[2] for the Type II nulls in 0834+06 and directly by Lang[3] for Type I nulls in 1133+16 and 1237+25.

The phenomena have been observed using linearly polarized feeds at 318 MHz and 606 MHz and a circularly polarized feed at 430 MHz. Further inspection of dual frequency recordings (318 MHz/111·5 MHz) from 0834+06, 1133+16 and 1237+25 shows that both types of nulls are correlated over hundreds of MHz.

The short duration, the correlation over a wide frequency range and the possible periodicity indicate that the radiation-producing structure is undergoing some rapid changes. Further interpretation will be presented following several detailed analyses.

First it should be stated that the Type II nulls in all but 1929+10 are most likely related to the class two effect which is observed in other pulsars. This has been suggested by Sutton *et al.*[1] for 0834+06 and will be shown to be true for 1237+25 in a separate paper. The type I nulls and the 1929+10 nulls could result from a particular form of the class two effect, but they are sufficiently different to warrant an independent discussion.

One measure of the significance of these nulls in a sequence of pulses is the distribution of pulse energies. Fig. 1 contains pulse energy distributions for pulses within a strong burst for three of the pulsars. A pulse energy is defined as the sum of the samples taken in a window on a pulse minus the sum of the samples taken in an equal length window adjacent to the pulse. The root-mean-square (r.m.s.) spread about the mean of the sums taken off the pulse is shown on each of the plots. The average signal-to-noise ratio, defined as the mean pulse energy divided by the off r.m.s. spread, is about twenty for each of the distributions. Because of this large ratio the effects of background and receiver noise are negligible. The peaks at zero pulse energy in the 1133+16 and 1237+25 distributions (Fig. 1*a* and *b*) indicate that the null pulses constitute a distinguishable group of pulses in these pulsars. For 1929+10 there is no peak at zero which means the nulls in a sequence of pulses are the sites of weak pulses. The significance of the 1929+10 nulls thus depends on other properties of the sequence.

Investigation of the intensity-time sequence sampled digitally from these pulsars shows that not only does the pulse energy drop suddenly at a null, but also that there is typically no pulsed radiation in the null pulses above a threshold intensity set near the noise level.

To determine the significance of the spacing of these nulls the consecutive pulse numbers of the null pulses, defined as those pulses during which the intensity was everywhere below a fixed threshold, were noted. A sequence of numbers was then formed with a positive integer at elements whose index was equal to a null pulse number and zeroes elsewhere. The sequence was transformed using a Cooley–Tukey algorithm to find a fluctuation power spectrum. The spectrum for 1929+10 resulting from the incoherent addition of twenty 256 point transforms is shown in Fig. 2. The response at 0·094 cycles/pulse period (*P*1) suggests that the nulls recur in this object with a characteristic spacing of 10·6 *P*1. This feature occurs near the frequencies of the feature reported for pulse energy spectra by Huguenin (unpublished) and Lang[4]. Thus either the zeroes in the sequence of pulse energies give rise to the feature or there are characteristic variations in the pulse energies synchronized with the nulls. For 1237+25 there is a feature in the null spacing spectrum resulting from a characteristic spacing of the Type II nulls of 2·8 *P*1 which agrees with the feature reported in the literature for pulse energy spectra. There may also be a longer characteristic period related to the Type I nulls, but the data were insufficient to make a definite conclusion.

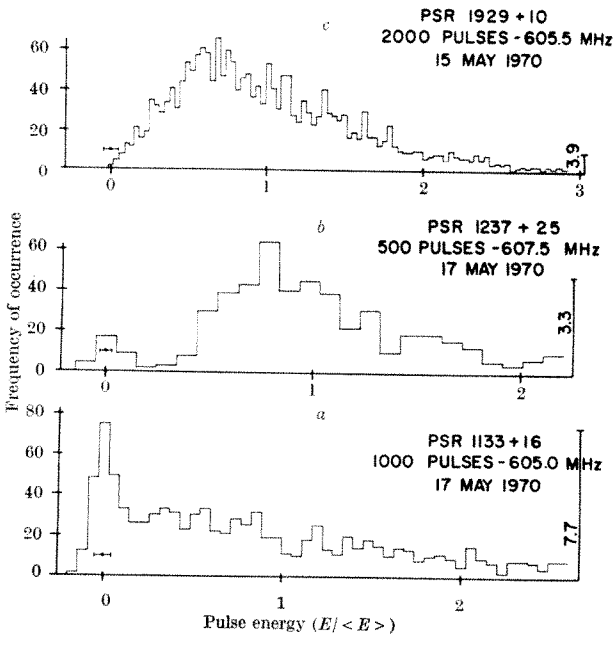

Fig. 1. Pulse energy distributions for *a*, 1133+16; *b*, 1237+25; and *c*, 1929+10. Zero indicates the average of the off sums and unity indicates the average of the on sums. The r.m.s. spread of the off sums is shown as error bars centred on zero. The number of pulse energies beyond the horizontal scale is shown as a vertical line on the right hand side of each plot; the number by this line is the maximum pulse energy in the sample.

For 1133+16 there is a feature due to the Type I nulls at 0·04 cycles/$P1$ in the null spacings spectrum which agrees with the feature reported in the literature for pulse energy spectra. There may also be a weak feature at 0·23 cycles/$P1$ due to the more frequent Type II nulls.

In order to determine the relation of the periodic nulls to the periodicity of pulse energies the pulses near 49 nulls in a sequence of 4,700 pulses observed at 606 MHz from 1929+10 were averaged together. As mentioned already, the nulls in 1929+10 tend to last only for one or two pulses. The sequence of nine pulses preceding and following the central pulse of the nulls were averaged together to obtain an average sequence (Fig. 3*a*). Although the null results from selecting the central pulse numbers for each member of the average sequence, it was found that 97 per cent of the pulse energies of the pulses averaged for a sequence number outside the null ($|N|>1$) were larger than the largest of those that constituted the central null pulse ($N=0$). The root-mean-square scatter from the mean of the pulse energies of the pulses averaged for a particular N was $\sim 0{\cdot}6$ times its mean for each N.

The average of all the pulses going into the average sequence was subtracted to see whether there were significant differences between the pulses preceding and following the nulls (see Fig. 3*b*). The positive residuals for $N>1$ indicate that the 1929+10 nulls are followed by an increase in pulse energy. Thus the pulse energy spectra would have a feature due not only to the periodic zeroes of the null pulses, but also to an enhancement that follows them.

The variation with N of the average pulse energy for a given N in the sequence is shown in Fig. 3*c*. The enhancement following the null is only marginally significant on the basis of this result. There are significant decreases in the average pulse energies at ± 12 and $+22/-24$ pulses. These were found to be only partially due to the periodicity which was detected in the power spectra of the null positions. The decreases were due also to the occurrence of weak pulses which do not satisfy the null criterion. This is further evidence of the source of the characteristic period in 1929+10.

As suggested earlier, this effect must be related to the structure producing the radiation. Most authors find that the radio emission must arise from the correlated motion of a group of charges, because coherent radiation is required to explain the inferred high brightness temperatures. Gold[5], for example, suggests that the group of charges are held in the magnetosphere of a rotating neutron star.

The Type I nulls and possibly the Type II nulls in 1929+10 indicate that some cause is periodically destroying most of the correlation for a small number of pulse periods. Within Gold's model this could arise from a perturbation of the magnetospheric trapping field which would dump the charges from the radiating region or from the onset of a plasma instability which would disperse the charges from the radiating region. As mentioned earlier, the Type II nulls are most likely related to the class two effect. Narrow marching subpulses with a spacing greater than the pulse profile could periodically cause a null pulse. This aspect of the phenomenon may be due to slow drifts of the group of radiating charges in the magnetosphere.

Fine Structure of Nebular Emission Lines

THE fact that nebular lines may have significant fine structure seems to have been neglected by nebular spectroscopists who have been considering the turbulent and thermal broadening of these lines. For example, Aller[1] and Courtès *et al.*[2], who have measured or interpreted the widths of the lines, do not mention this effect.

In particular Hα is composed of four components. Kent *et al.*[3], Lewis and Spedding[4] and Spedding *et al.*[5] showed experimentally, for a laboratory source, that only the two principal components, of nearly equal brightness, were significant. They are separated by 0·14 Å. Sommerfeld and Unsöld[6,7] and Schrödinger[8] calculated theoretically the relative brightnesses of this fine structure. These depend strongly on the conditions of excitation.

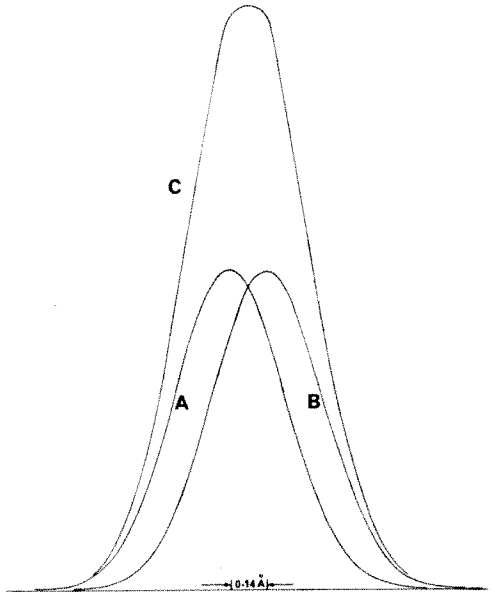

Fig. 1. Thermally broadened component of the Hα line composed of two Gaussians A and B.

It is interesting to estimate the error introduced into the measurements of the electron temperatures of HII regions from the width of the Hα line if the fine structure is neglected. Consider the case shown in Fig. 1 where the thermally broadened component of the Hα line is composed of two Gaussians A and B of equal brightness, where each has a thermally broadened width of 0·506 Å corresponding to a nebular temperature of 10,000 K and where these two components are separated by 0·14 Å. The thermally broadened component of the Hα line would then appear as the summation, C, of these two curves. This has a half-width of 0·545 Å. If this were inadvertently considered to be a single Gaussian representing the thermal component of the Hα line, then the electron temperature would be given wrongly as 11,880 K. This indicates an error of around +2,000 K. It is then possible that every measurement of temperature of gaseous nebulae that has relied on the width of the Hα line and which has neglected this splitting is then 2,000 K overestimated. Those methods that depend on the widths of [NII] and Hα (ref. 2) are even further uncertain if the fine structure of this forbidden line is also neglected.

It would seem necessary to consider the fine structure of all the nebular lines in the conditions existing in nebulae when making exact measurements of their widths and shapes.

Apex of Solar Motion of Neutral Hydrogen Concentrations at Different Velocities

De Vaucouleurs and Peters[1], Kerr and Sullivan[2] and I[3] derived the solar motion with respect to the high velocity HI clouds (HVCs) with a view to examining the suggestion by Verschuur[4] that these cloud complexes and the Local Group of galaxies form part of the same extragalactic system of objects. They concluded that the solar motion solution does not seem to justify Verschuur's hypothesis. Kerr and Sullivan[2] also derived the solar motion with respect to a sample of 125 intermediate velocity clouds (IVCs) and concluded that they seem to be kinematically distinct from the HVCs.

Dieter[5] used the data from the Berkeley neutral hydrogen survey (2 km s^{-1} velocity resolution) to show that in almost every case high velocity condensations occur where there is evidence of excess gas at more moderate velocities. Using these data she also found evidence for physical interaction between gas masses at different velocities at the same location in the sky. This relation between gas at different velocities was based on her study of the velocity dispersion of the IVCs associated with the HVCs and also on the column densities of neutral hydrogen atoms.

In order to see if her data, which showed a physical relation between gas masses at different velocities, also showed a kinematic relationship, I divided her list (Table 1 of ref. 5) of 139 hydrogen condensations into two groups—(1) 68 with velocities greater than 70 km s^{-1} and (2) 71 with velocities less than 70 km s^{-1}—and derived the solar motion with respect to the local standard of rest separately for the two groups. The solutions are shown in Table 1. These results may be compared with those derived by de Vaucouleurs and Peters[1], Kerr and Sullivan[2] and me[3] (Table 2).

Table 1. SOLAR MOTION SOLUTIONS RELATIVE TO LOCAL STANDARD OF REST

< 70 km s^{-1}	71	148°±13°	−12°±12°	91±9

Table 2. RESULTS OF EARLIER WORK

	N	$l^{II}_{\odot}$	$b^{II}_{\odot}$	$V_{\odot}$ km s^{-1}
de Vaucouleurs and Peters[1] (HVCs)	17	139°±16°	−13°±13°	184±66
	16	148°±7°	−12°±5°	234±29
V. R. V. (HVCs)	17	139°±20°	−13°±16°	184±66
Kerr and Sullivan[2] (HVCs)	62	136°	−4°	222±19
Kerr and Sullivan[2] (IVCs)	125	138°	+42°	58±3

Kerr and Sullivan's solution for IVCs is different from my solution for gas at less than 70 km s^{-1}. This may be due to the inclusion in their sample of 125 of a large proportion of IVCs that are not associated with HVCs.

It is seen from my solution (Table 1) that the apex of solar motion of gas with velocities greater than 70 km s^{-1} is not very different from that for gas with velocities less than 70 km s^{-1}. The apices are in the galactic plane which seems to suggest that the gas concentrations are related to the galaxy. The close agreement between the direction of the solar motion of the two groups suggests that they

may have a common dynamic origin which, perhaps, is a super-supernova explosion as proposed by Rickard[6].

Penetration of Solar Particles to Ionospheric Heights at Low Latitudes

Ganguly and Rao recently presented evidence for the possibility of the penetration of high energy solar particles to ionospheric heights at the equator[1]. Their letter, based on ionospheric absorption data obtained at Calcutta (geomagnetic latitude 12° 15′ N), together with optical observations of solar flares and tabulated proton flux data, is very interesting in the light of extensive work recently on the penetration of solar particles to low magnetospheric L-values ($L \sim 4$–$7\ R_E$) at the equator[2–7]. Because the observations of Ganguly and Rao would have a profound and far-reaching impact on current ideas of the mechanisms for the access of such solar particles to the geomagnetic equator[2–4,6], the ionospheric and solar evidence presented by the Calcutta group has been examined carefully. We conclude that there is little basis for their contention that solar particles can penetrate directly to low altitudes and thus influence ionospheric absorption at the equator.

Ganguly and Rao present perhaps their most conclusive evidence in their Fig. 2. They plot, as a function of time, the night-time absorption (for 4·7 MHz) and the "proton flux ($E > 60$ MeV) measured by Explorer 33" for the period 1400 UT August 1 to 0300 UT August 2, 1967. Proton data ($E \sim 60$ MeV) measured by the Bell Laboratories instrument on ATS-1 at the equator (150° W geographic longitude) at synchronous altitude were examined for evidence of a solar particle enhancement occurring around the time reported in ref. 1. No evidence for such an enhancement was found.

The $E > 60$ MeV proton data from the solar proton monitoring experiment on Explorer 34, published routinely in the ESSA bulletin *Solar Geophysical Data*[8], were examined for a proton enhancement as presented by the Calcutta group. During the time period discussed by Ganguly and Rao, Explorer 34 was at perigee and thus measuring the electron radiation belts by electron pile-up in the proton channels[9]. It was found that the $E > 60$ MeV data presented by Ganguly and Rao were equal to the fluxes reported by the Explorer 34 solar proton monitoring experiment during its perigee-pass through the radiation belts. Hence we conclude with respect to the "correlation" presented in Fig. 2 of the letter by Ganguly and Rao that: (1) ATS-1 data give no evidence of a solar proton enhancement at high altitudes at the equator; (2) Ganguly and Rao were evidently using Explorer 34 and not Explorer 33 data in their comparison; (3) the data they plotted were the perigee-pass data when the satellite detector was measuring the radiation belts.

We have examined the optical flare data and the solar proton data from ATS-1 and Explorer 34 during the three periods of anomalous absorption presented in Fig. 1 of Ganguly and Rao. The optical flare data which we used were those in the master list of flares and subflares compiled by World Data Center A and published in *Solar Geophysical Data*[10]. Although not stated explicitly in their caption to Fig. 1, Rao informs us that the data were plotted in Indian Standard Time (IST = UT + 5·5 h).

The flare that occurred between 0337 and 0352 UT, February 11, 1968, was classified as −N (ref. 10). The flare that occurred between 0416 and 0439 UT, February 14, 1968, was classified as 1B (ref. 10). No evidence of high energy solar protons was observed at synchronous altitude on ATS-1 at the time of either of the two absorption events which Ganguly and Rao associated with these flares. Explorer 34, located in the magnetotail, also measured no high energy solar protons. A small flux of low energy (≤ 5 MeV) solar protons was observed on both ATS-1 and Explorer 34 throughout February 14. The flare that Ganguly and Rao reported as occurring between 0820–0840 UT, February 7, 1968, was classified as 1F in the list of "Small or Unconfirmed" flares[10]. No solar protons in any energy range were observed on either satellite during this day.

We conclude with respect to the three February 1968 flare events in Fig. 1 of Ganguly and Rao that the solar proton data do not support the authors' contentions that high energy protons contribute to low altitude equatorial absorption at Calcutta. We further note that the three February 1968 flares used by Ganguly and Rao were smaller than the flares that generally produce high energy proton fluxes at the Earth.

In summary, we find the evidence for correlation of proton events with low altitude equatorial absorption to be invalid, and find the supporting flare data to be unconvincing and unsupported by spacecraft measurements.

We thank Miss E. Ruth Hedemann of the McMath-Hulbert Observatory, University of Michigan, for comments on optical flare reporting and publication, and Dr M. Rao for comments on the first draft of this letter.

Transform Faulting in the Thai Peninsula

RECENT mapping by a joint UK/Thai team of geologists[1], operating under the Colombo Plan, has shown that the angular elbow-like feature in the Phuket area of peninsular Thailand projecting into the Andaman Sea is the physiographic expression of two major transcurrent faults with a total sinistral displacement of at least 200 km.

A zone of rich tin-bearing granites stretching up the Malay Peninsula into Thailand as far as Surat Thani has been offset by both faults. Across the largest of these, the Khlong Marui Fault, the belt has been displaced a distance of at least 150 km to the south-west to Phuket Island, whence it continues up the western part of the Thai Peninsula to Ranong (Figs. 1 and 2*c*). Across the Ranong Fault the tin-bearing zone has again been displaced at least 20 km to the south-west and the offset northern part of the zone passes through the islands of

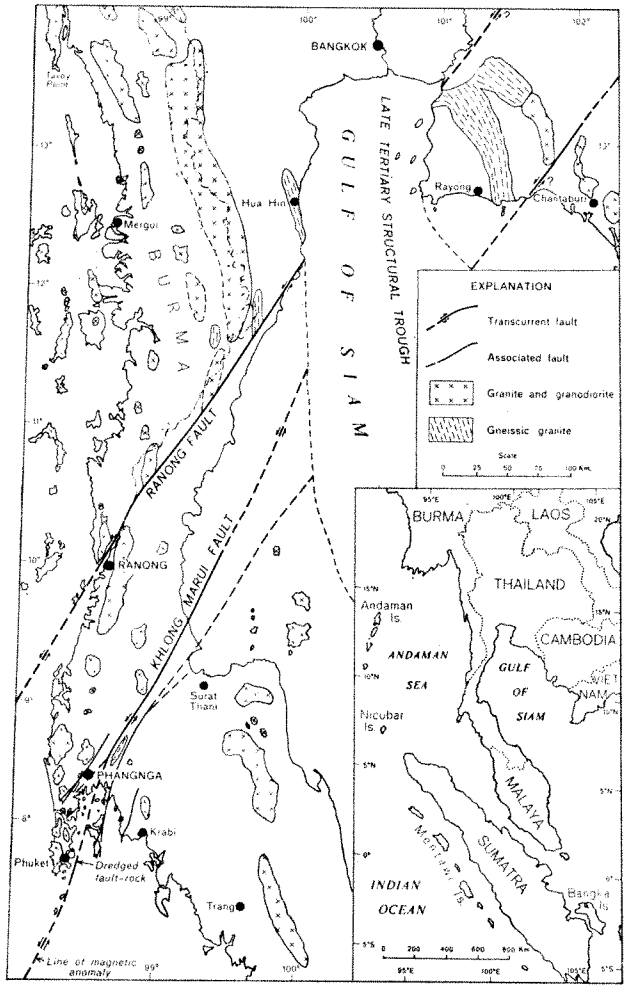

Fig. 1. Location of transcurrent faults and granitic rocks in peninsular Thailand and Burma.

the Burmese archipelago and the granitic hills adjacent to the coastline.

The Khlong Marui and Ranong Faults probably converge in the Gulf of Siam under a thick cover of late Tertiary sediments within a structural trough[2] to form a single fault which displaces the Rayong gneissic granites to the Hua Hin area. These sediments are currently being investigated by several oil companies; the location and age of the faults in the gulf are therefore of major significance. Projected to the south-west of the peninsula, the principal Khlong Marui Fault coincides with the submarine slope at the edge of the Malacca Straits[3] and also with a NE-trending magnetic anomaly[4].

In the Phuket–Phangnga area there is a close relationship between the NE-trending transcurrent fault system and a parallel swarm of tourmaline-pegmatites and lepidolite-pegmatites, both worked extensively as tin ores. The latter are possibly the largest unzoned lepidolite-pegmatites yet recorded anywhere in the world, and are apparently unique in south-east Asia[5]. Related lineated granites occupy a graben in a fault-valley traced across the peninsula from Phangnga to north of Surat Thani.

The age of the faulting is not yet established with certainty. It, however, certainly post-dates emplacement of the late Carboniferous to Triassic granites of the Chantaburi[6] area which are affected by these transcurrent movements. At Ranong, adamellites dated at 111 ± 6 m.y. and 113 ± 8 m.y. using the Rb : Sr method[6] are displaced by the Ranong Fault. It is considered that the NE trending tourmaline-granites are a late phase of these granites and were intruded into fractures in the zone of transcurrent faulting. A significant period of mica rejuvenation is recorded at 65 m.y. in the Thai–Malay Peninsula[6,7] and we believe this may be related to the final consolidation of the transcurrent fault system.

The location of the faults in a zone of Mesozoic plutonic activity and on the concave side of the arcuate Sunda mobile belt of Cainozoic and late Mesozoic age suggests that the movements were related to the development of the Sunda arc. Large lateral displacements terminating at one end in a mobile belt can most simply be interpreted in terms of the ocean floor spreading hypothesis[8] and the concept of plate tectonics[8,9] as movements along transform faults[10,11].

One of the more genetically significant features of the faults is that the south-western end of the Khlong Maru Fault, and probably that of the Ranong Fault, lies at or near the junction of the Sumatra and Andaman–Nicobar segments of the Sunda arc. The Sumatra arc lies on the south-western margin of the Sunda Shelf, the western margin of which continues northwards as a major bathymetric and topographic feature through the Andaman Sea and Shan Scarp in Burma. The shallow depth of the Sunda Shelf and the presence of broad positive gravity anomalies[12] suggest that its crust has a thickness approaching that of continental crust. The crust on the concave side of the Andaman–Nicobar island arc is of oceanic type[13,14]. Thus the faults terminate at or near the point where a mountain arc lying on crust of continental type meets an island arc located on oceanic crust.

According to the concept of plate tectonics, the seismic and volcanic activity in the Sunda arc is related to the descent of north-eastward spreading lithosphere along an inclined Benioff zone[15,16]. The trend of the actively volcanic east of the Mentawi Island chain therefore suggests that lithosphere was descending beneath the Mentawi Islands at that time. Thus the eposide of lithospheric descent which in the Andaman–Nicobar–Mentawi island belt ended in the late Cretaceous had started beneath the Mentawi Islands segment of the belt by early Cretaceous times.

Most of the Andaman–Nicobar arc is below sea level, and there is no evidence for the time at which lithosphere started to descend beneath the zone now occupied by these islands. We suggest that the lateral displacements along the Khlong Marui and Ranong Faults can most simply be explained if descent of lithosphere beneath this zone began before that beneath the Mentawi Islands, probably in late Jurassic times. We also suggest that, before this episode of differential movement between the plates, the area of continental-type crust to the south-east of the present faults lay 200 km south-west of its present position (Fig. 2*a*). During the late Jurassic to early Cretaceous episode of lithospheric descent this crustal segment remained coupled to the spreading ocean floor, moving north-eastwards as spreading continued (Fig. 2*b*). The resulting differential horizontal movement between this southern plate, which included Sumatra, Malaysia and and the Sunda Shelf, and the northern plate, which included the Thai Peninsula and Andaman Basin, led to transform faulting, most of the displacement occurring along the Khlong Marui and Ranong Faults.

By the early Cretaceous the margin of the Sunda Shelf plate had moved to its present position, approximately in line with the Andaman–Nicobar islands, and became uncoupled from the ocean floor. Lithosphere then began to descend beneath the zone now occupied by the Mentawi Islands (Fig. 2*c*), resulting in the early Cretaceous volcanic activity in the Gumai and Garbai ranges. Adamellites were intruded at Ranong at about the same time. Loss of lithosphere beneath this zone and beneath the belt now occupied by the Andaman–Nicobar islands ceased in the late Cretaceous, resulting in infilling of the submarine trench, which was uplifted during the late Tertiary to form the present islands. Since the beginning of the Tertiary,

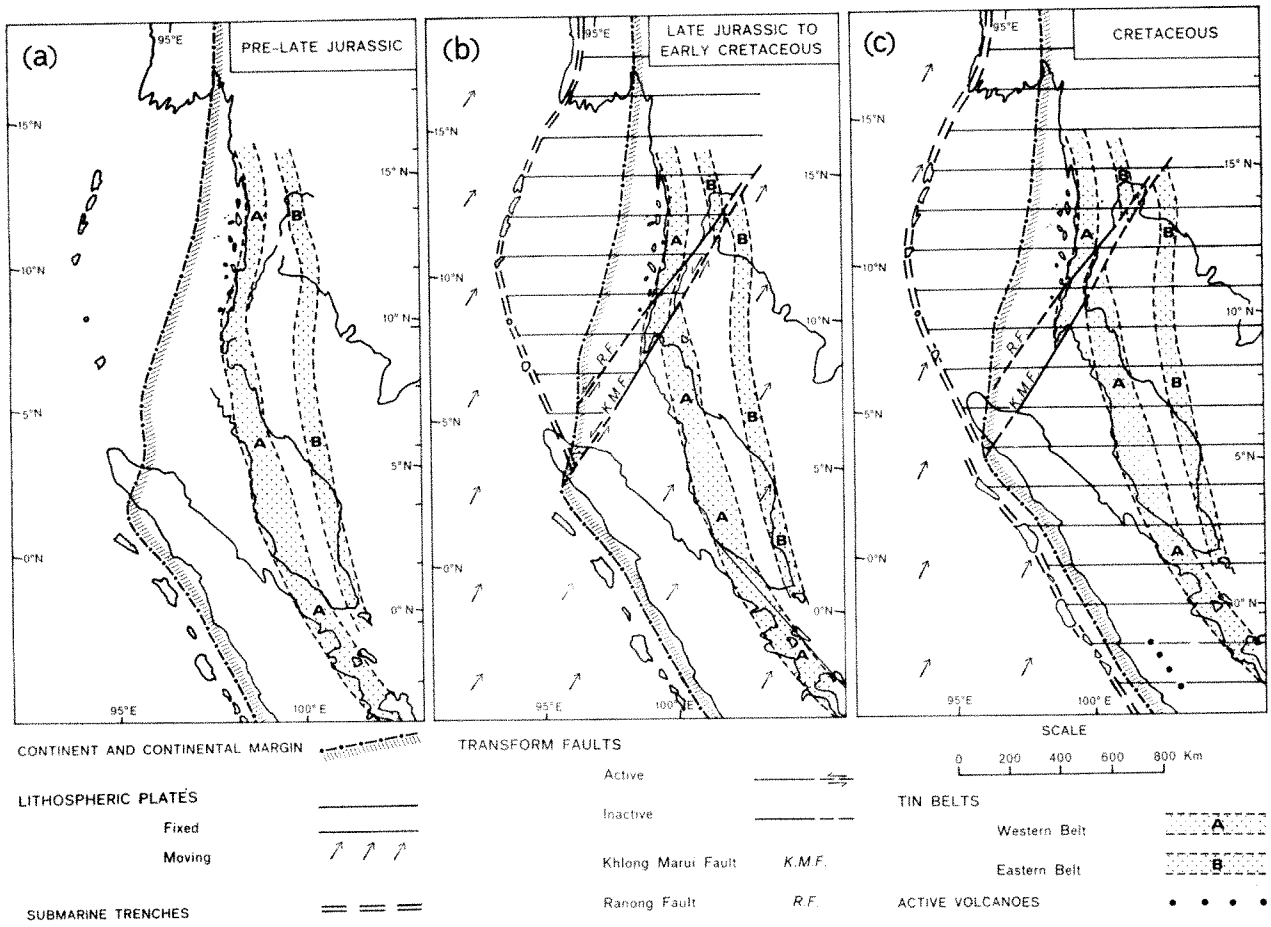

Fig. 2. Proposed relationship of ocean floor spreading and descent of lithosphere to fault movements in the Thai-Malay Peninsula in the late Mesozoic.

spreading lithosphere has been lost, either continuously or intermittently, along a Benioff zone which approaches the surface beneath the Sumatra trench and to the west of the Andaman–Nicobar Islands, and transform fault movements have not been renewed.

Bottom Melting of Ice Shelves and the Mass Balance of Antarctica

The world sea level is estimated[1,2] to be rising by approximately 1 mm yr^{-1}. Attempted explanations[3,4] have considered heating of the oceans, release of juvenile water, a reduction in atmospheric humidity and melting of the polar ice sheets. Existing evidence[5] does not indicate any pronounced warming of the deep ocean waters, and most of the rise in sea level probably results from wastage of glaciers.

Giovinetto[4], however, has concluded that much of the Antarctic ice sheet has a positive net balance. He assumes appreciable net accretion of ice on the bottom surface of the principal floating ice shelves, which make up about 7 per cent of the area of the ice sheet. Here we present experimental data from the Brunt Ice Shelf which cannot be reconciled with this assumption (a detailed analysis will be published elsewhere). Bottom melting rates of 0·8 m yr^{-1} are measured at 70 km from the ice front, and we consider that significant bottom freezing can take place only in very special conditions.

By estimating the rate of change of thickness of the ice shelf and using continuity and hydrostatic equilibrium equations, Swithinbank[6] and Crary[7,8] deduced bottom melting rates of 0·87 and 0·63 m yr^{-1} near the ice fronts of the Maudheim and Ross ice shelves respectively. Another method, analysis of the temperature/depth curve, has been applied to the "Little America" bore hole through the Ross Ice Shelf (refs. 7, 9, 10 and unpublished results of G. de Q. Robin in a paper at the Antarctic Symposium, Buenos Aires, 1959); but the necessary data are difficult to collect and are relevant only to the site of

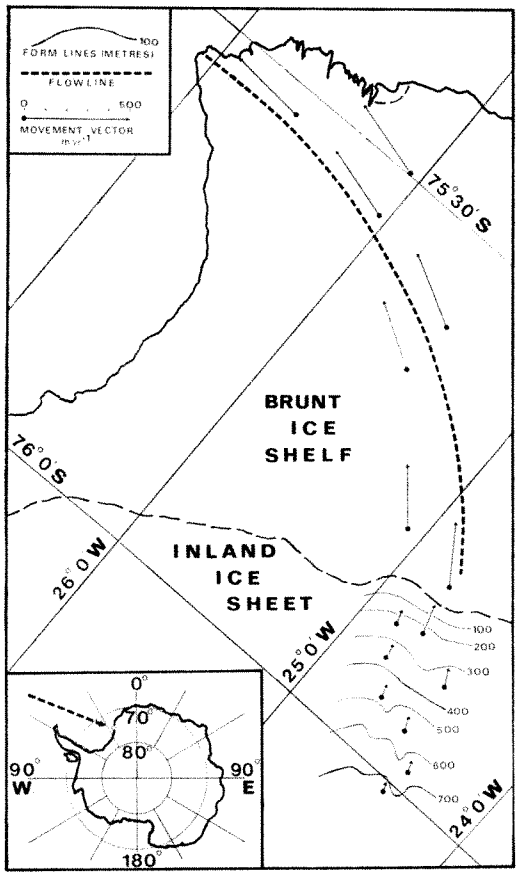

Fig. 1. The western part of the Brunt Ice Shelf, showing the flow line along which measurements were made of snow accumulation, strain rates, ice shelf velocity, thickness and surface elevation. Inset shows position of Brunt Ice Shelf.

the bore hole. The kinematic method can be applied to determine bottom melting rates at frequent intervals across an ice shelf.

Following Shumskiy and Zotikov[10] we adopt a system of fixed rectangular coordinates with x-axis along a flow line at sea level and z-axis downwards. We assume the ice shelf to be in steady state (elevation, thickness and mean density are functions of x only), and that the seawater density, ρ_w is a constant.

The continuity and hydrostatic equilibrium equations then reduce to

$$\dot{A}_b + \dot{A}_s + Z_b \dot{E}z\, \rho_w - u\rho_w \tan\beta = 0$$

where subscripts s and b refer to the upper and lower surfaces; $\dot{A}$ is the accumulation rate (bottom melting rate $= -\dot{A}_b$); $\dot{E}z$ the vertical strain rate ($-$ve for compression), equal to $-(\dot{E}_1 + \dot{E}_2)$ where E and $\dot{E}_2$ are the principal strain rates at the surface; u the ice shelf velocity along the flow line; and β the slope of the lower surface.

The Brunt Ice Shelf is one of several small ice shelves fringing the eastern coast of the Weddell Sea (Fig. 1). During 1966–70 the net accumulation of snow on the surface, the rate of movement of the ice shelf and horizontal strain rates were measured at points on a flow line which extended for 72 km from the junction of the ice shelf with the inland ice sheet to the ice front[11]. Surface elevations were measured to $\pm 0{\cdot}1$ m by optical levelling. Ice thickness was measured by radio echo sounding from an aircraft in January 1970 (information made available by the joint SPRI/US National Science Foundation programme of airborne echo sounding, 1969/70). A thickness profile to ± 10 m was obtained, and bottom elevations were calculated by subtracting the measured thickness from known surface elevations.

To simplify computation of a continuous profile of bottom melting rates along the flow line, polynomials $y = P(x)$ were fitted to the measured parameters (y) (see Fig. 2). By fitting polynomials of low order to the upper and lower surface elevation profiles, the upper surface undulations and the lower surface "noise" could be smoothed out to leave the overall slope characteristics of the profiles.

The bottom melting-rate profile is shown in Fig. 2 with the first order line of regression superimposed. Large errors are likely in the values of bottom slope taken over small distances; although the mean bottom melting rate is within $\pm 0{\cdot}15$ m yr^{-1}, individual points may be in error by 0·5 m yr^{-1}. This source of error, however, cannot account for the larger deviations from the regression line, which we believe to result from non-steady-state conditions. Near the ice front increased melting takes place, though not to the extent implied by the profile. Because of the intermittent calving of icebergs, steady-state conditions do not apply, and ice shelf thinning can be accurately estimated only by repeated measurements. Surface elevations were regularly measured at points near the Brunt Ice Front; corresponding bottom melting rates show a rapid approach to steady state conditions over the first 10 km from the ice front (Fig. 2).

Other published estimates of bottom melting rates are given in Table 1. All except Crary's results are based on measurements of surface slope (α) and an assumed value of the variable ratio β/α, the uncertainty of which has limited the accuracy of the calculations.

Behrendt[14] concluded that the extreme melting rates calculated for the Filchner Ice Shelf were incorrect because of non-steady-state conditions near the ice front; but he

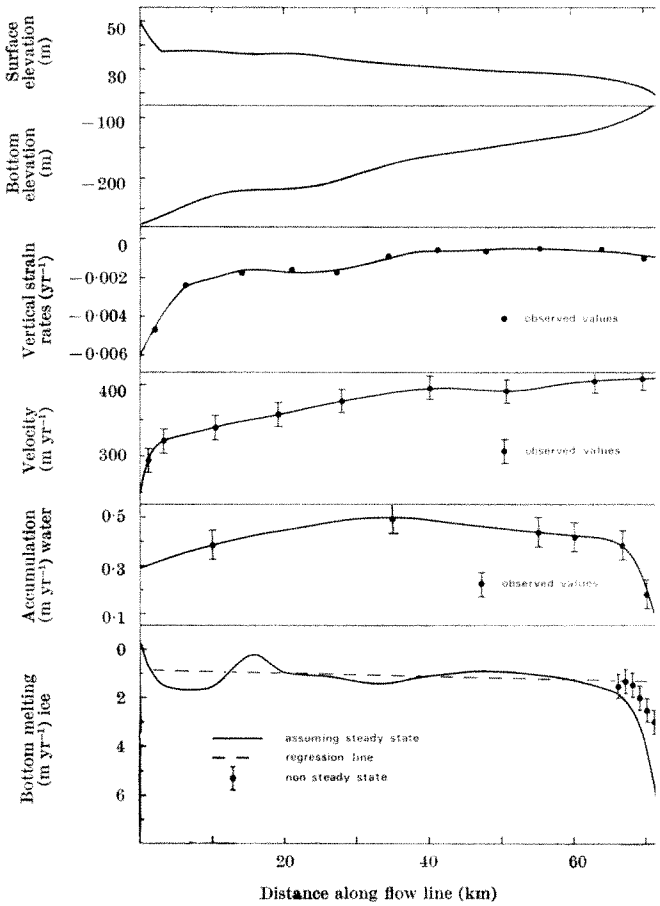

Fig. 2. Plots of polynomials fitted to the various parameters measured on the Brunt Ice Shelf, and a profile showing melting rates beneath the ice shelf assuming steady state flow.

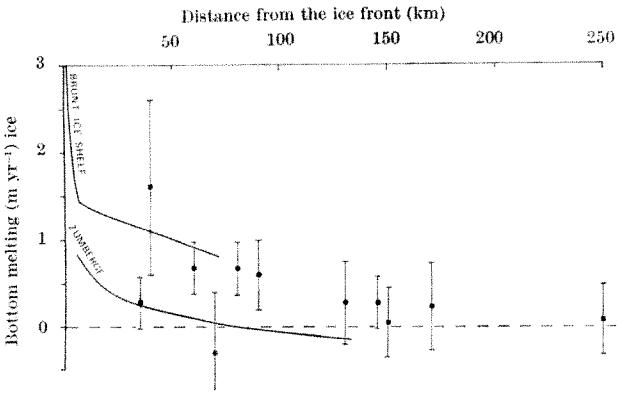

Fig. 3. Melting rates computed by the authors for the Amery (■) and Ross (●) ice shelves. A profile of bottom melting beneath Brunt Ice Shelf is included together with that proposed by Zumberge[17] for the Ross Ice Shelf.

found a high melting rate even 50–100 km back from the ice front.

Budd[12] used measurements of surface slope calculated from elevations determined by pressure altimetry. Measurements by optical levelling (W. Budd, personal communication), however, make it possible to compute more accurate bottom melting rates for the Amery Ice Shelf. Similarly, on the Ross Ice Shelf, velocity measurements[15], radio echo sounding of the ice thickness (B. M. E. Smith, personal communication), measurements of snow accumulation[16] and strain rates (E. Dorrer, personal communication) have been used to compute the bottom melting rates shown in Fig. 3, together with those for the Amery and Brunt ice shelves.

Table. 1. PUBLISHED ESTIMATES OF BOTTOM MELTING RATES. THE VALUE FOR THE ROSS ICE SHELF NEAR ROSS ISLAND WAS COMPUTED BY THE AUTHORS FROM THE DATA OF PAIGE[13]. THE NEGATIVE VALUE REPRESENTS BOTTOM FREEZING.

Source	Position	Bottom melting rate (m yr⁻¹) of ice
Swithinbank[6]	Maudheim Ice Front	0·9
Crary[8]	Ross Ice Front (Little America V)	0·6
Budd[12]	Amery Ice Shelf: 150 km from ice front	−0·1
	250 km from ice front	0·2
Paige[13]	Ross Ice Front (near Ross Island)	1·3
Behrendt[14]	Filchner Ice Front	9·6

To fit earlier data from the Ross Ice Shelf, Zumberge[17] proposed a bottom melting profile (Fig. 3) that required bottom freezing at distances from the ice front greater than 80 km, with a minimum freezing rate of 0·1 m yr^{-1} at 130 km. Robin[18] questioned this figure on the grounds of steady-state heat flow. He assumed that all heat absorbed by the ice shelf was used to warm downward moving ice, and concluded that the maximum freezing rate beneath the Ross Ice Shelf would be about 0·02 m yr^{-1}. This would correspond to a situation in which the ice shelf had trapped a body of seawater[19], isolating it from any supply of heat from ocean currents.

We conclude that there can be very little bottom freezing on any ice shelf; it probably occurs only beneath thin ice shelves, such as the ablation area of the Ross Ice Shelf in McMurdo Sound[20], or where the ice shelf has trapped beneath it a body of seawater.

Until more data are available it would be unwise to offer a quantitative assessment of the total loss of ice from Antarctica by bottom melting, but we are led to question the validity of recent estimates[4] of a positive balance for the major drainage basins.

We thank the British Antarctic Survey for sponsoring the work, Dr G. de Q. Robin for making available the facilities of the Scott Polar Research Institute, the US National Science Foundation for radio echo sounding flights made during the joint SPRI/NSF programme, and Dr Charles Swithinbank for encouragement and helpful suggestions.

Optical Transmission and Reflexion Gratings by Laser Evaporation

We wish to report a new technique for the manufacture of optical transmission and reflexion gratings. The gratings are formed by the action of standing light waves in a ruby laser cavity on thin metallic films deposited on glass substrates within the cavity (Fig. 1).

We used two ruby laser systems, one a Bradley laser type 302 which had a very inhomogeneous beam; the other was a more refined system, with a Brewster angled ruby rod. At first two mirrors of 100 per cent reflectivity were used in the cavity, but we found that more controlled evaporation was possible with one of the mirrors only partially reflecting. Rough stack mirrors[1] were also used with success. In both laser systems gratings were produced over an area of about 10 mm^2, with rulings up to 2,000 lines mm^{-1}.

Most of our experiments have been carried out with gold films 20·0 to 10·0 nm thick, deposited on smooth float glass. Gratings were also produced using silver films. The films cause a loss in the cavity which vanishes when oscillations start the Q of the cavity suddenly increases and the laser output is a high power giant pulse. This is

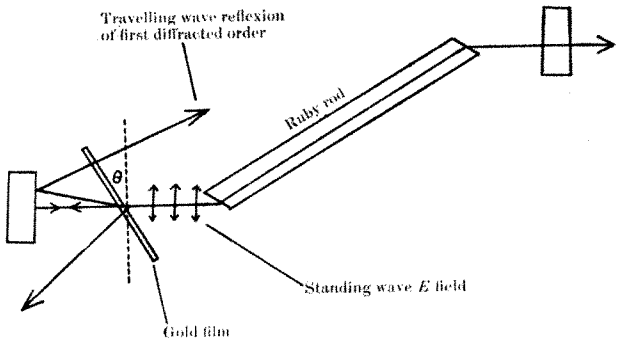

Fig. 1. Technique for producing diffraction gratings by laser evaporation.

a standard Q-switching method[2,3] producing peak powers of the order of 10 MW in our experiments.

When oscillations start, evaporation takes place at the anti-nodes[4] of the electric field forming a grating within the laser burn. On two films the diffracted first order travelling wave after one reflexion in the cavity mirror also burnt the film. As expected, this burn did not show any diffraction effects.

The number of lines per mm, n, can be varied by changing the angle θ between the film and the normal to the cavity axis, because

$$n = \frac{\sin\theta}{\lambda_R/2}$$

where λ_R is the wavelength of ruby light. Gratings were produced for various values of θ, and n was calculated from the results of normal incidence first order diffraction experiments. The graph (Fig. 2) is a straight line, showing good agreement with theory.

The gratings were examined using a helium–neon laser. Fig. 3 shows the reflected and transmitted first and second order diffracted beams. Spraying the gratings with a protective clear lacquer did not seem to affect their performance. Some of the glass substrates were examined after the metal film had been dissolved, and the glass was found to be etched, giving faint diffraction patterns. We intend to investigate the latter phenomenon as part of the current programme of work at this college on laser damage.

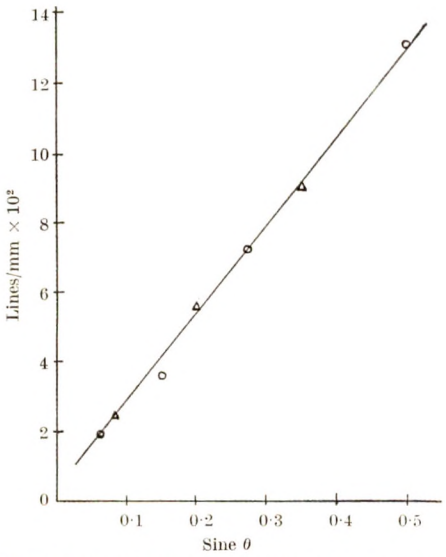

Fig. 2. Laser evaporated gratings. Graph of lines mm^{-1} as a function of film angle, θ, within the cavity. ○, Bradley type 302 laser; △, Brewster angled laser system.

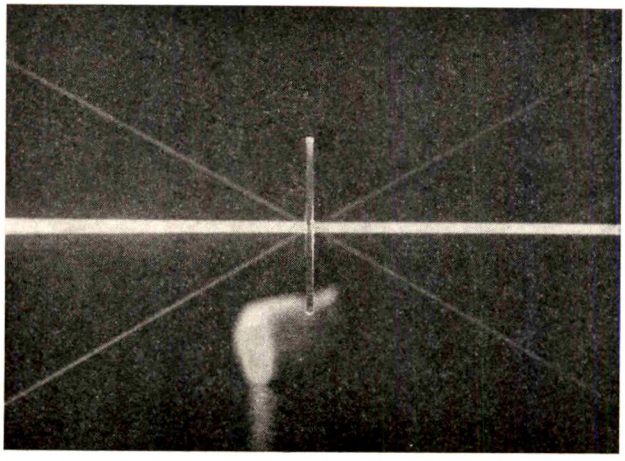

Fig. 3. Transmitted and reflected, first and second diffracted orders by a laser evaporated grating with 715 lines mm^{-1}. Incident radiation 632·8 nm.

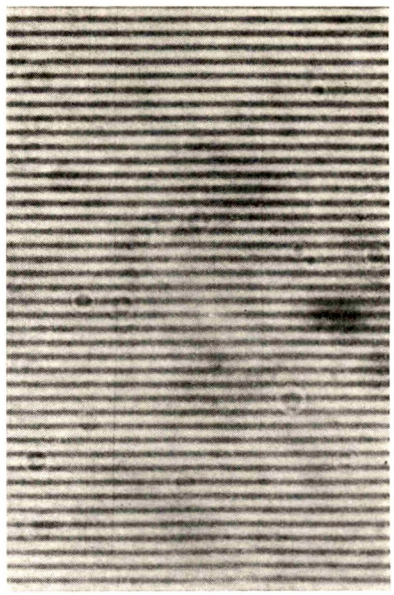

Fig. 4. Laser evaporated grating photographed by transmission microscopy. The grating period is 2,500 nm.

The uniformity of the rulings of this kind of grating can be assessed from Fig. 4. In this case the line spacing was 2,500 nm.

Using this technique the length of grating which can be made seems to be limited only by the length of the laser cavity and the available laser power. The width of the grating is determined by the width of the laser beam—usually only a few mm. The grating spacing could conceivably be as small as 250 nm if frequency doubled ruby laser light were used, and there is no reason to believe that the quality of the rulings would be any worse than those shown in Fig. 4. Development work is proceeding along these lines.

We thank Professor S. Tolansky and Mr M. Thyer for Fig. 4 and Mr D. Hambley for preparing suitable gold films. R. W. and D. M. R. are supported by Science Research Council research studentships.

Liquid Crystals in Molten Salt Systems

Because of the strong long range forces acting between the molecules, molten salts constitute a highly distinctive class of liquids. Up to now, however, the variety of stable ionic melts studied has been largely confined to

the simplest ions, such as inert gas type halides, nitrates, and network forming oxides and fluorides. Through the establishment of procedures for achieving chemical stability in molten salts with organic anions[1,2], the variety of these ionic melts available for investigation and use is potentially greatly increased. Distinctive microstructures and unusual properties might be expected for at least some of these liquids. We illustrate these possibilities here with new observations on liquid crystals, stable over a wide interval of temperatures, formed by melts of sodium isovalerate and related salts. This group of substances differs in several ways from well known classes of liquid crystals, which include chiefly rod-shaped molecules, with long rigid parts[3].

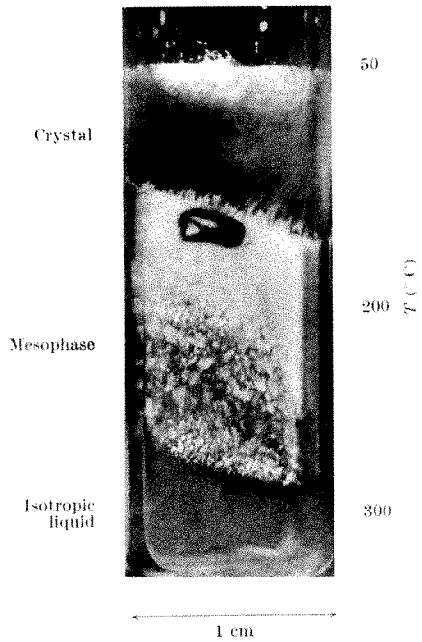

Fig. 1. Macroscopic view of 3 phase sample of sodium isovalerate in polarized light.

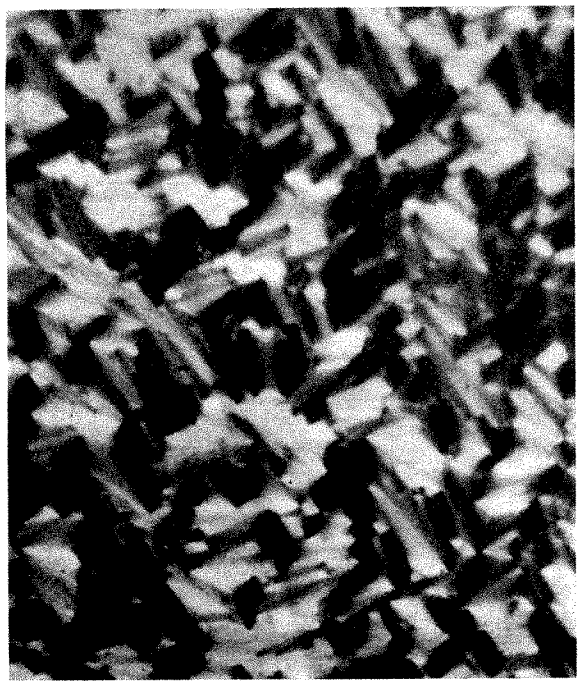

Fig. 2. Microscopic view of sodium isovalerate. Polarized light; temp = 200° C; ×50 (original magnification ×100).

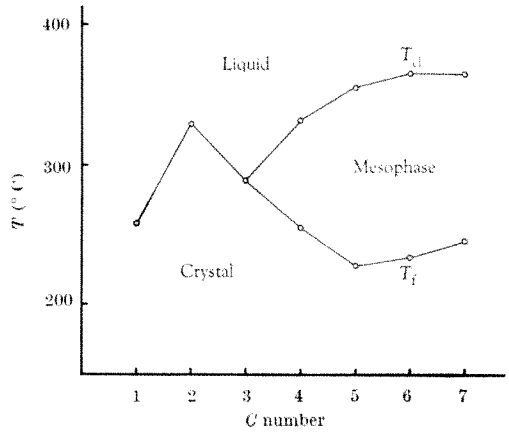

Fig. 3. Transition temperatures of sodium salts of fatty acids against C number.

In systematic studies of the physico-chemical properties of organic ionic melts, we have observed thermotropic mesomorphic behaviour in sodium salts of fatty acids even of low carbon number ($n < 6$). Anions in these compounds are quasiglobular, and do not show any obvious geometrical anisotropy, although this had generally been considered a condition for the formation of liquid crystals[4]. Although the mesomorphic behaviour of these salts was briefly reported some sixty years ago[5], to our knowledge no attention has been given since that time to this behaviour in compounds of low molecular weight. Mesomorphic behaviour is, of course, well known for alkali salts of longer chain fatty acids ($n > 10$) (ref. 6).

The thermal stability of molten sodium isovalerate and the extended temperature range ($\Delta T > 100°$ C) of its mesomorphic phase provide good examples of recent developments in our researches. We also include here brief data on sodium propionate, which show a fugitive mesophase extending only 1° above the melting point, and on sodium *n*-butyrate the mesophase of which is stable over a wider range of temperature, but the melts of which are less stable than those of sodium isovalerate. All these salts were prepared following a procedure described elsewhere[2].

Birefringence is one of the most conveniently identifiable properties of liquid crystals. Fig. 1 shows sodium isovalerate contained in a 'Pyrex' cuvette (1 cm depth) observed in plane-polarized light travelling towards the observer normal to the container face. A temperature gradient within the sample allows the three phases to co-exist (isotropic liquid, mesophase, and solid). The mesophase is seen to be strongly birefringent. When the melt is slowly heated towards the mesophase–isotropic transition, it breaks up into strongly coloured domains (second order of colours). This phenomenon occurs in the bulk of the liquid, and can therefore hardly be attributed to the wall orientation effects which are sometimes found for liquid crystals.

Chromatic polarization is usually observed in birefringent crystals cut in thin plates with faces parallel to the optic axis. Because the birefringence observed for sodium isovalerate is relatively high, comparison with other mesophases that show this property[7] would suggest that an extensive two dimensional ordering of its molecules occurs spontaneously.

Some additional information about the nature of the mesophase has been obtained from hot-stage (200° C) microscopic examination (×100) in polarized light of sodium isovalerate mounted as a film between a glass slide and a cover slip. The pattern observed (Fig. 2) resembles the "A type" exhibited, for instance, by the classical smectogenic compound di-*n*-hexyl-4,4′-azoxycinnamate. This type has been described as a "Fächerstruktur"[8].

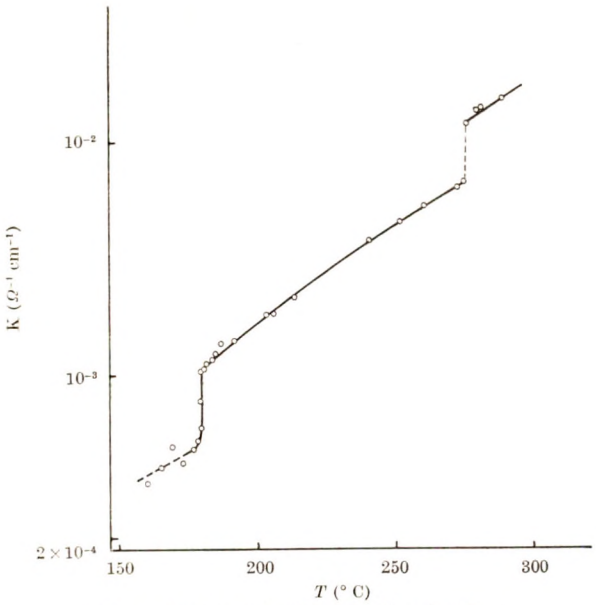

Fig. 4. Specific conductivity of sodium isovalerate

Fig. 3 records the transition temperatures we observed for some sodium carboxylates plotted against the number of carbon atoms in the organic anion. As the number of carbon atoms in the anion is increased, the strong long-range electrostatic forces are progressively diluted by the organic fraction, for which interaction forces are of much shorter range. This trend brings with it mesomorphic phases stable over extended regions of temperature.

‡ Ref. 13.
§ Perkin–Elmer data.

Calorimetric data have been obtained using a Perkin–Elmer differential scanning calorimeter (model DSC-1B). The heating rate used was 16°/min. Estimated enthalpies and entropies for the various melting mechanisms are recorded in Table 1. Although the results are not yet sufficiently precise for evaluation of specific heats, they may be usefully compared with data for typical non-ionic liquid crystals, included in Table 1 for convenience. Although our new data are provisional, it is clear that entropies of fusion of the salts are far smaller than for molecular liquid crystals of classical types, so far as these have been determined. Small solid–solid transitions were also observed at about 78° C for sodium isovalerate and at 178° C and 246° C for sodium *n*-butyrate. These probably resemble the transitions found in solid acetates[1], but will not be further discussed here.

In the interval of temperature between the onset of melting T_f and the clearing point T_{cl}, mesophase ionic melts exhibit remarkable transport properties. For convenience of description, this intermediate state of these molten salts has been provisionally referred to above as "liquid crystal". Measured with a conventional capillary viscometer, a high viscosity of about 100 poises at 260° C has been found for sodium isovalerate in the mesomorphic state. Above its clearing point, the viscosity drops to 0·7 poise. These results may resemble the viscosity changes from 200 poises for smectic ethyl *p*-azoxybenzoate, to $<0{\cdot}05$ poise at its clearing point[10]. Such sharp decreases may be contrasted with the change in viscosity on passing from nematic to isotropic *p*-azoxyanisole[11]. Detailed measurements, however, are needed to characterize the molten salt mesophases more precisely in this respect.

Electrical conductance changes observed for sodium isovalerate are recorded in Fig. 4, in a semi-logarithmic plot against temperature. These values were determined using a low constant cell (0·263 cm^{-1}) with an a.c. bridge at 1 kHz. The jump in specific conductivity $\varkappa$ in passing from crystals to the "liquid crystal" melt (a factor of about 160) is comparable with the jump on passing from "liquid crystal" to isotropic melt (a factor of about 100). Nominal activation energies in Arrhenius plots of log $\varkappa$ against $1/T$ are 8·15 kcalories/mole for the mesophase and 12·2 kcalories/mole for the isotropic ionic melt. Both are lower than for crystalline sodium isovalerate (about 30 kcalories/mole). Present findings indicate that changes in conductivity do not run parallel to the observed changes in macroscopic viscosity of the molten salts. More information is needed to elucidate the mechanisms of ion-drag in the various phases of sodium isovalerate.

An alternative explanation for the remarkable mechanical and optical properties now observed might be that the cation lattice in crystalline sodium isovalerate becomes positionally disordered at T_f while the anion lattice retains long range correlations between neighbours, until the clearing point T_{cl} is reached. By way of comparison, certain silver salts show positional melting of the cation lattice many tens of degrees before their anion lattice melts[14]. Jumps in conductance on attaining positional disordering of the cation lattice in a salt such as silver iodide are comparable with those now observed for sodium isovalerate, and there may thus be an analogous sequence of melting mechanisms in the two groups of salts. If this alternative suggestion about the microstructure of these organic ionic melts is well founded, the "liquid crystal" state of sodium isovalerate might in fact be more correctly described as a plastic solid with extremely low elastic limit. Even for moderate shear stresses, a plastic crystal with almost zero elastic limit is likely to resemble a "liquid" of very high viscosity, with certain customary methods of measuring this property. More detailed studies on the properties and microstructure of these remarkable liquids, which are being made, should help to clarify these problems. In the meantime, the ready availability of these novel anisotropic "liquids" may prove to be of use in a wide variety of studies.

MIRVs and the Strategic Balance*

BELLANY[1] claims that the introduction of multiple independently targeted re-entry vehicles (MIRVs) could increase the stability of the strategic balance between the US and the Soviet Union. This conclusion is not warranted, and in fact quite the opposite is true.

The measure of stability adopted by Bellany is based solely on the number of warheads that survive a first strike by the opposing power. I shall present several arguments to show why this criterion is unsatisfactory. In the model in which the forces of the two major powers are assumed to be equal, Bellany's basic equation is

$$X = nN(1-C)^{fnR} \qquad (1)$$

Here N is the number of launchers on each side; n is the MIRV ratio (number of warheads per missile); R is a reliability factor (probability of successful launch); C is the probability that a target missile silo is destroyed by a single warhead; and f is the fraction of its launchers that country A employs in a hypothetical (counterforce) first strike. X is then the number of B's warheads expected to survive such an attack. By maximizing X with respect to n, holding all other parameters fixed, Bellany obtains an "optimum" MIRV ratio.

Does the "optimum" situation thus derived actually entail an increase in stability? Consider the numerical example used by Bellany: $R = 0{\cdot}75$, $f = 1$, $C = 1/2$; for simplicity, take $N = 1{,}000$. The situation with and without MIRV is then as follows

	$n=1$ (no MIRV)	$n=2$	$n=3$
Initial warheads on each side	1,000	2,000	3,000
Warheads B has left after A's first strike	625	706	645

$n = 2$ is the optimum MIRV ratio according to Bellany's criterion. The introduction of MIRV has achieved a modest (I am tempted to say, trivial) increase in the number of surviving warheads, at the cost of doubling the initial number of warheads on each side. Perhaps a would-be first striker will feel somewhat more deterred. But a much more important consideration has been ignored by Bellany. Imagine a crisis situation, in which each side fears the other may attack, even though neither has a true first-strike capability. (I regard this as a more likely prelude to nuclear war than a coldly premeditated first strike.) In such a situation, military leaders will weigh the risks and advantages of a pre-emptive attack against those of waiting and perhaps letting the opponent get in the first blow. Even with a MIRV ratio of only 2, pre-empting will reduce the opponent's force by a factor of almost 3; if the opponent should strike, one's own force will be similarly depleted. The advantage of striking first is always much greater with MIRV than without. This is the very essence of instability.

Bellany has also maximized X with respect to only one parameter, n. If we complete his calculation by similarly finding the optimum value of N, obviously, this value is infinite and, according to Bellany's criterion, the most stable situation is one in which each side possesses an infinite number of launchers, each missile containing some finite number of warheads. If the number of launchers is held fixed, say, by international agreement, the procedure of maximizing only with respect to n becomes more justified. But the other criticisms remain equally valid even in this case.

Equation (1) can be used to demonstrate another reason why MIRV is destabilizing. The values for accuracy, hardness, and so on used by Bellany are fairly representative of present capabilities. The trend in missile technology, however, has been toward ever improving accuracy, and we must take account of the likelihood that targeting errors will be reduced substantially below their present values. The parameter C is extremely sensitive to missile accuracy; it is given by the relation

$$1 - C = 2^{-K/CEP^2} \qquad (2)$$

where CEP is the r.m.s. targeting error and the constant K depends on the yield of the weapon and the hardness of the silo. If $C = 1/2$ when $CEP = 0{\cdot}25$ miles (these are the numbers used by Bellany), then a reduction of CEP to 0·1 mile (not at all outside the range of possibility) increases C dramatically, to more than 99 per cent. Even by Bellany's criterion, the optimum MIRV ratio then falls well below unity. More important, when C is close to unity, X rapidly approaches zero as n increases. The combination of high accuracy and MIRV is extremely dangerous: It can lead to a situation in which each side has a first-strike capability with respect to the other's fixed missiles. This would be about the most unstable situation imaginable.

One can hardly expect countries to deploy MIRVs now and voluntarily dismantle them later, when improved accuracy makes them a potential first-strike weapon. Any agreement to refrain from incorporating higher accuracy in an existing MIRV installation would be subject to the well known difficulties in verification.

I conclude that the introduction of MIRVs, at any ratio, would have a highly destabilizing effect on the strategic balance.

I thank S. Weinberg and P. Morrison for helpful suggestions.

L. SARTORI

MIT Department of Physics,
Cambridge, Massachusetts.

Received June 15, 1970.

[1] Bellany, *Nature*, **226**, 412 (1970).

MAY I reply to Professor Sartori's points roughly seriatim?

Let me say first that I was careful not to be dogmatic about what actually constituted a more or a less stable balance. My choice of the number of surviving warheads as a measure of stability was made because it seemed plausible that decision makers would think, even in periods of crisis, in terms of numbers of targets threatened—roughly proportional to number of warheads—and of how well they might defend these targets with ABM defences—again closely related to the number of attacking warheads to be engaged. Professor Sartori wishes to substitute this criterion by one where the incentive to strike first is measured by the inverse fraction of total warheads expected to remain after a first-strike attack. He may be right.

Second, I am glad Professor Sartori has been good enough to illustrate my contention that there is an optimum value for the number of MIRV warheads per launcher. That he has gone farther and demonstrated that the number of warheads surviving a first strike is, near the turning-point, a slow moving function of the MIRV number adds weight to my general contention that MIRVs do not necessarily threaten a serious upset to the strategic balance.

Third, my justification for maximizing X with respect to n is simply that the number of launchers, N, is the only parameter at all likely to be fixed at some future date by political agreement, as Professor Sartori himself concedes.

Finally, the fact that, by my criterion, as missile accuracy increases the optimum MIRV number falls below unity merely bears out what Professor Sartori has to say about the effects of increasing accuracy and does not strike me as giving him much cause for complaint on that point. Might I, however, complain that while Professor Sartori's discussion of the effects of increasing accuracy is, as far as it goes, unexceptionable, it does not go far enough? He

* An article on this subject was also published in *Nature*, **227**, 696 (1970)—*Editor.*

has forgotten to allow for the effects of ABM defence of, in this case, offensive missile installations. As he may know, even the crude current techniques of ABM defence are likely to be at their most effective when employed in defence of targets already partially protected against nuclear attack, such as offensive missile emplacements. This factor alone will prevent the probability of an offensive missile emplacement (a silo) being destroyed by a single warhead rising, as missile accuracy increases, anywhere near as fast as he suggests.

Mutagenic Methods for determining which DNA Strand is transcribed for Individual Viral Genes

THIS work describes two mutagenic methods for determining which strand of the DNA double helix is transcribed. The approach is applicable to viruses which contain single-stranded DNA in the mature form. The analysis identifies which strand is transcribed for a given viral gene.

The usual method for determining the transcribed DNA strand is by DNA–RNA hybridization. Using phage φX174, Hayashi, Hayashi and Spiegelman[1] compared the ability of phage-induced mRNA to hybridize with the single-stranded mature phage DNA and with the double-stranded replicative form. Because the bulk of the mRNA hybridized with the double but not the single-stranded DNA, most of the mRNA must be copied from the complementary strand of the replicative form. But the hybridization data do not exclude the possibility that a small portion of mRNA hybridized with the single-stranded DNA, which would mean that one or a few genes may be transcribed differently. Because the mutational analyses we describe are gene specific, we have re-examined this problem using phage S13, which is closely related to φX174[2].

The transcribed DNA strand can be identified for individual genes of single-stranded DNA phages by studying the induction of *ochre* (UAA)[3] mutants because two of the three possible transition mutations of the *ochre* codon produce other nonsense codons (Fig. 1). This situation makes it possible to determine from mutagenesis experiments alone whether the DNA triplet in the mature virus and the corresponding RNA codon are complementary or homologous (with T replacing U).

The first method used to identify the transcribed strand was to study whether *ochre* mutants could be induced from wild type by particular transition mutations. The only sense codon related to *ochre* by a transition is CAA, which codes for glutamine (Fig. 1). If the mRNA and the mature phage DNA are homologous, then C→T (CAA→TAA) is the only transition which can produce an *ochre* from a sense codon; if they are complementary, G→A (TTG→TTA) is the only transition which can produce an *ochre*. To identify the transcribed strand by induction of *ochres* from sense, it is necessary to use a mutagen that may induce G→A or C→T but not both. The mutagen can also induce other mutations provided they are transitions; the qualification is necessary in order to restrict the origin of the *ochre* to the glutamine codon.

Hydroxylamine, which induces only C→T transitions[4], was used to study the induction of *ochres* from wild type in bacteriophage S13 (Fig. 2, method *A*). Induction of an

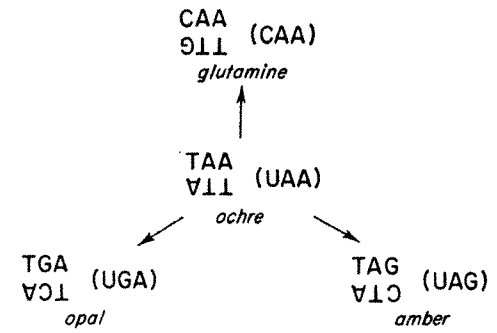

Fig. 1. Codons related to the *ochre* by one-step transitions. Both the homologous and complementary DNA triplets are shown next to the corresponding RNA codons which are in parentheses.

ochre in a given gene with hydroxylamine would prove that the mRNA and mature phage DNA are homologous for that gene. But failure to induce an *ochre* with hydroxylamine would not prove that the mRNA and phage DNA are complementary because there are other reasons why an *ochre* might not be observed even if the mRNA and phage DNA are homologous. One reason for this is that the gene might not contain the CAA triplet anywhere in its DNA.

The second method used to identify the transcribed strand was to study whether *ochre* mutants could be induced from *opal* (UGA) nonsense[5] mutants. If the mRNA and DNA are homologous, then only a G→A (TGA→TAA) transition can produce an *ochre* (Fig. 1). When complementary, only C→T (TCA→TTA) produces an *ochre*. Any mutagen which induces a G→A or a C→T transition, but not both, can be used to identify the transcribed strand. Hydroxylamine was again used to study the inducibility of *opal*→*ochre* in S13. An *ochre* is inducible from an *opal* only when the mRNA is complementary to the mature phage DNA (Fig. 2, method *B*). The same argument applies to the induction of *amber* (UAG)[3]→*ochre* but it is more difficult to study this mutation because of the problem of selection; *ochre* suppressors in the host suppress both the *amber* and *ochre* codons. It was possible, however, to study one example of *amber*→*ochre*.

Method *B* is more general than method *A*, because *B* can be used successfully to identify the transcribed strand for a gene either when the mRNA and DNA are complementary or when they are homologous, while *A* can succeed only when they are homologous.

To apply these mutagenic methods, it is necessary to be able to distinguish the *amber*, *opal* and *ochre* nonsense mutants from each other. Table 1 shows that the three types of mutants can be identified by their growth patterns on different cell strains.

To identify genes having mRNA homologous to the mature phage DNA by method *A*, *ochres* were induced with hydroxylamine[4] from S13 wild type[6]. *Ochres* were found in genes I, II, IIIa-IIIb, IV and VI (Table 2). Establishing that an *ochre* occurs in either gene IIIa or IIIb is sufficient to establish for both genes that the mRNA is homologous

Table 1. GENERAL GROWTH PATTERNS OF PHAGE NONSENSE MUTANTS ON VARIOUS STRAINS OF *E. coli*

Cell:	CA165·2		C600·1	T_3A-2·1[8]	WWU[9]		C	
	str^s	*str*^{r}			*su*$^-$	*su*$^+$	*str*^{s}	*str*^{r}
Phage								
Ochre	+	+/0*	0	0	0	0	0	0
Amber	+/0	+/0	+	0	0	+	+/0	0
Opal	+/0	+/0*	+	+	+/0†	+/0†	+/0	0

* The *str*^{r} allele greatly decreased the suppression of many *opal* mutants but only slightly affected suppression of *ochres*. For several allelic *opal-ochre* pairs the efficiency of plating (eop) of the *opal* was relatively low (eop of *opal*/eop of *ochre* $\leqslant 10^{-5}$). Thus it was easy to select mutations from *opal* to *ochre* by using CA165·2 *str*^{r}.

† A given *opal* mutant had the same eop on both *su*$^-$ and *su*$^+$ strains.

+/0 indicates that some phage mutants grow and some do not.

Other cell strains showed at least some suppression of S13 *opal* mutants. *E. coli* KB, KT*su*$_{UAG}$, AB1157*su*$_{UAG}$, CR63*su*$_{UAG}$, KMBL146(CR34)*su*$_{UAG}$ and *Shigella dysenteriae* Y6R*su*$_{UAG}$.

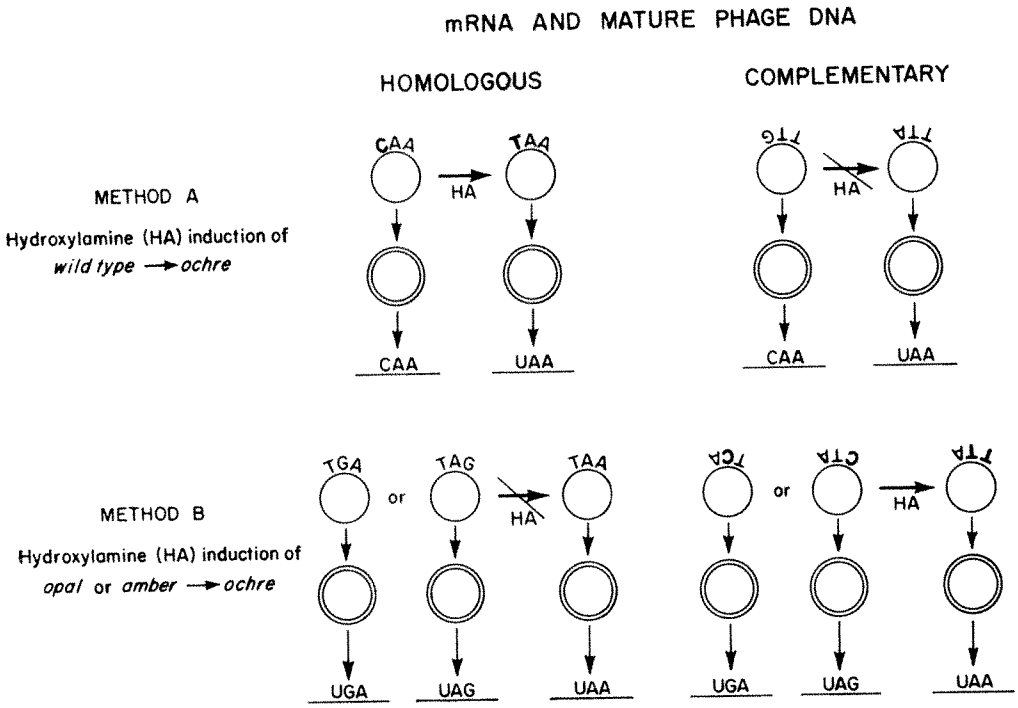

Fig. 2. Two mutagenic methods identifying the transcribed strand of phage S13. The diagram represents the conversion of single-stranded mature phage DNA (single circle) to double-stranded, intracellular replicative-form DNA (double circle) and the production of phage specific mRNA (straight line). The DNA triplets are shown on the single circles and the mRNA codons are on the straight lines. The heavy arrows indicate mutagenesis. The bases C and T are shown in heavy letters wherever they are involved in hydroxylamine-induced mutations. Hydroxylamine, which is specific for C→T transitions, can induce an *ochre* mutant from a sense codon only when the mRNA and mature phage DNA are homologous (method *A*). When the mRNA and DNA are complementary, two DNA triplets, TCA and CTA, could be mutated by hydroxylamine to an *ochre*, but both correspond to nonsense. An *ochre* can be induced from an *opal* or an *amber* by a C→T transition if the mRNA and phage DNA are complementary. If they are homologous, a C→T transition cannot convert an *opal* or an *amber* to an *ochre*.

to the phage DNA because polarity of nonsense mutants in gene IIIa has shown that both genes are translated from the same mRNA[7]. No conclusion can be reached about the two remaining genes, V and VII[2], because no *ochres* were found.

Confirmation of these results was obtained by method *B*. The ability of hydroxylamine to induce *opal*→*ochre* and one *amber*→*ochre* was tested (Table 3). These *opal* and *amber* mutants were at the same sites as the *ochres* induced in the preceding experiment. Although the *ochres* had been induced by hydroxylamine, none of the *amber* and *opal* mutants could be mutated. Nitrous acid was used as a control mutagen because it can induce both G→A and C→T transitions[4] and therefore should induce the *ochres* regardless of which DNA triplet corresponds to the UGA or UAG codon. As expected, all the mutants were induced to *ochre* with nitrous acid. The mutants used in these experiments were in genes II, IV, IIIa-IIIb, and VI. The homology of the mRNA with the viral DNA was therefore verified for these genes.

Table 2. INDUCTION OF WILD TYPE → *ochre* BY HYDROXYLAMINE

Gene	Induction frequency × 10⁸ Hydroxylamine*	Spontaneous
I	9·6	< 0·1
II	23·5	< 0·1
IIIa–IIIb†	4·5	0·2
IV	3·5	0·2
V‡	< 0·1	< 0·1
VI	16·5	< 0·1
VII‡	< 0·1	< 0·1

* The induction frequency is expressed per lethal hit.
† It was not necessary to determine whether these *ochres* are in genes IIIa or IIIb (see text).
‡ No *ochres* were isolated in gene V or gene VII.
Wild-type phage were treated[4] with hydroxylamine to a survival of 0·2. Fifty-five mutants were isolated by replica plating and placed into complementation groups[10]. The spontaneous frequency was measured by replica plating of unmutagenized phage.

Table 3. INDUCTION OF *opal*→*ochre* AND *amber*→*ochre*

Gene	Mutant	Induction frequency/lethal hit × 10⁷ Nitrous acid	Hydroxylamine
II	*opal*	400	< 0·7
IIIa–IIIb	*amber**	320	0·8
IV	*opal*	340	< 0·3
VI	*opal*	350	< 2·6

* It is not known if this mutant is in IIIa or IIIb (see text).
Although *ochre* suppressors in the host suppress both *ambers* and *ochres*, the *amber* mutant grows poorly enough on the *ochre* suppressor strain for the *ochre* to be selected. Each *amber* or *opal* mutant tested was induced with 5-bromodeoxyuridine[11] from the *ochre* mutants described in Table 2. CA165-2 *str*^{r} was used to select *ochres* from *opals*, and CA165-2 was used to select the *amber* from the *ochre*. *Ochres* were identified by spot testing on appropriate cell strains (Table 1). The induction frequencies for hydroxylamine are not significantly higher than the spontaneous frequencies.

We made several attempts to isolate mutants in other genes so that hydroxylamine inducibility of *opal*→*ochre* could be studied. *Opals* were induced from the wild type by nitrous acid, but it was found that all these *opal* mutants occurred in previously tested genes. Also, no *opals* were found after treatment of the wild type with hydroxylamine. Finally, *ochres* were isolated with nitrous acid. It was intended to convert the *ochres* to *opals* and then test as in method *B*. But again, all the mutants observed were in genes that had already been tested.

From this mutational analysis it can be concluded that for six of the eight[2] known genes of S13-φX174, the transcribed RNA strand is homologous to the mature phage DNA. These results extend the earlier hybridization studies[1] which did not exclude the possibility that one or more genes may be read on the complementary strand. Because the genetic analysis is gene specific, this possibility can be eliminated for six genes.

These genetic or mutagenic methods for determining the transcribed strand have been applied to a single-stranded DNA phage, but they also can be applied to any organism in which viable complementary DNA strands can be separated and single-base substitutions can be identified. They can also be applied to RNA viruses.

Specific Inhibition of Influenza Replication by α-Amanitin

α-AMANITIN, a bicyclic polypeptide from the toadstool *Amanita phalloides*[1], is known specifically to inhibit the DNA-dependent RNA polymerase of mammalian cells by interaction with the enzyme rather than with the DNA template[2,3]. No influence of the toxin on the replication of a number of DNA or RNA-containing viruses has been found so far (ref. 4 and personal communication from L. Philipson). Actinomycin, which reacts with the DNA template and so impairs the DNA-dependent RNA polymerase reaction, depresses the multiplication of influenza viruses but does not interfere with the replication of most of the other RNA-containing viruses[5–7]. Because the mode of action of this antibiotic on the synthesis of influenza viruses is still obscure, we extended our studies to the action of α-amanitin on the multiplication of this virus group.

As a model system for influenza virus the fowl plague virus (FPV) strain "Rostock" and, as a control, a parainfluenza virus (Newcastle disease virus, NDV) were propagated in chick fibroblasts. The plaque test and the determinations of viral neuraminidase, haemagglutinin and the inner component (RNP-antigen) were performed according to standard methods. Viral plus and minus strand RNA were determined by the hybridization technique[8]. Viral RNA polymerase activity was assayed in a cytoplasmic extract prepared 5 h after infection[9].

FPV multiplication is inhibited completely by 50 μg/ml. of α-amanitin, whereas NDV multiplication is not affected (Table 1). FPV replication is even more efficiently blocked when the inhibitor is added to the cultures 2–3 h before infection. This holds true not only for the infectivity, but also for the amount of haemagglutinin, neuraminidase and RNP-antigen (Table 2).

Table 1. DOSE EFFECT OF α-AMANITIN ON THE YIELD OF FPV AND NDV

α-Amanitin (μg/ml.)	HA units		P.f.u. $\times 10^{-6}$	
	FPV	NDV	FPV	NDV
0	256	32	110	140
1	224	32	110	250
10	32	32	14	150
25	4	32	8	—
50	< 2	32	2	—
100	< 2	32	1·9	150

The toxin was added immediately after infection. The cell-associated virus-specific activities were determined 8 h after infection after breaking the cell by freezing and thawing three times.

Table 2. EFFECT OF α-AMANITIN ON THE SYNTHESIS OF VIRUS-SPECIFIC RNA *in vivo*, AND ON THE PRODUCTION OF OTHER VIRAL COMPONENTS

	No α-amanitin	25 μg/ml. α-amanitin added 2·5 h before infection
Radioactivity (d.p.m.) in:		
Total RNA	71,500	34,000
Plus strand	5,700	1,700
Minus strand	4,300	320
Cell-associated parameter:		
HA units	128	1
P.f.u. $\times 10^{-5}$	33	1·6
RNP-antigen titre	64	4
Neuraminidase units	520	38

To each of three FPV-infected cell cultures 100 μCi of ^{3}H-uridine was added 2·5 h after infection. When α-amanitin was investigated, 200 μCi ^{3}H-uridine was investigated. Total RNA was extracted by sodium dodecyl sulphate plus phenol 3·5 h after infection. Viral plus and minus strand RNA was determined by hybridization[8].

Up to 50 μg/ml. of α-amanitin had no influence on the incorporation of ^{3}H-uridine or ^{3}H-leucine into the corresponding macromolecules of uninfected cells, when the isotopes and the toxin were administered simultaneously. If the pulse was given 3 h after the addition of α-amanitin there was also no significant effect. Six hours after addition of the inhibitor, however, the uptake and phosphorylation of ^{3}H-uridine and RNA and protein synthesis reached only about 50 per cent of the values for untreated cells.

The results in Table 2 demonstrate that a substantial amount of viral plus strand RNA is still being synthesized in conditions when the plaque test indicates a twenty-fold inhibition of FPV multiplication. The production of viral minus strand RNA, however, is barely measurable. A similar result has been obtained recently using mithramycin as an inhibitor of RNA synthesis[10]. FPV-specific RNA polymerase, which synthesizes chiefly minus strand RNA[11] *in vitro*, was not inhibited by 180 μg/ml. α-amanitin. There is no measurable inactivation of FPV by incubating the virus for 16 h with 60 μg/ml. α-amanitin at 4° C.

The results indicate that α-amanitin inhibits specifically influenza virus replication without interfering significantly with the overall synthesis of RNA and protein in the host cell. The delayed effect on these activities might be rather a non-specific toxic alteration of the metabolism in our cell system, which is essentially different from the systems used by others[2,3]. At this time the multiplication cycle of FPV is in any case completed, so that it is not very probable that α-amanitin inhibits influenza virus multiplication by interfering with cellular RNA synthesis as has been discussed for the action of actinomycin[5,7]. Because much viral RNA is still being synthesized in the presence of α-amanitin, it could be that this inhibitor also affects some step of the translation of viral RNA.

We thank Professor Th. Wieland of the Max-Planck-Institut für Medizinische Forschung, Heidelberg, for a gift of α-amanitin, and Miss H. Krombach and Miss B. Piontek for technical assistance. The work was supported by the Deutsche Forschungsgemeinschaft.

Tryptophan tRNA of *Escherichia coli*

THE tryptophan tRNA of CAJ64, a UGA suppressing strain of *Escherichia coli*[1], has an altered structure compared with that isolated from the wild type (CA244). A complete account of this work will be published elsewhere, but the sequence shown in Fig. 1 has two points of immediate interest. First, both the su$^+$ and su$^-$ structures contain an adenosine at position 15 and a uridine at position 48. In most other tRNAs guanosine and cytosine, respectively, occupy homologous positions in the sequence. Another exception with adenosine and uridine in these positions has recently been found in a leucine tRNA of *E. coli*[2]. The three dimensional model proposed by Levitt[3] has hydrogen bonds between the bases in these positions; these coordinate base changes are consistent with the structure and lend support to this feature of it.

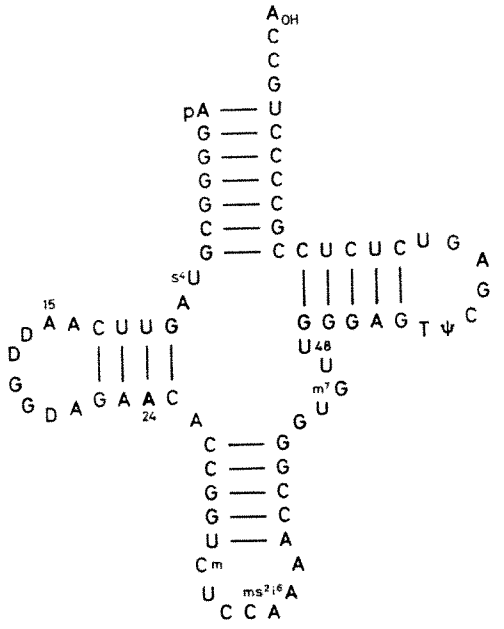

Fig. 1. Nucleotide sequence of *E. coli* (strain CAJ64) tryptophan tRNA. The unusual nucleoside 3′-phosphates are abbreviated as s^4U for 4-thiouridine, D for dihydrouridine, Cm for 2′-O-methyl cytidine, Ms^2i^6A for 2-methylthio-6-isopentenyl adenosine, m^7G for 7-methyl guanosine, T for ribosyl thymine, and Ψ for pseudouridine (5-ribosyl-uracil).

Second, both the su$^+$ and su$^-$ sequences have the same anticodon sequence, CCA, which according to the predictions of the wobble hypothesis[4] should recognize the codon UGG alone. The only difference between the two sequences is that the su$^-$ has a guanosine instead of an adenosine at position 24. Evidence has been obtained to show that there is no other tryptophan tRNA (less than 3 per cent of the amount found) in the su$^+$ strain, that both the su$^+$ and su$^-$ tryptophan tRNAs can read UGA, and that the mutant alteration allows the su$^+$ sequence to do this more efficiently.

Amino-acid Composition of Crayfish Trypsin

THE homology in primary structure of mammalian pancreatic serine proteases is well established[1,2]. Progress has now been made in the elucidation of the evolutionary history of this group of proteases. Neurath and his co-workers[3] studied the amino-acid composition of trypsinogen isolated from the pancreas of the spiny Pacific dogfish and presented a preliminary examination of the primary structure of this enzyme. From these data a high degree of homology as compared with bovine trypsinogen can be inferred. It is now of interest what will be found beyond the gap that separates vertebrate and invertebrate animals. Invertebrate proteases are difficult to investigate because of the small amounts of material obtainable from these animals. In the crayfish *Astacus leptodactylus* we found an enzyme resembling mammalian trypsin in many respects[4,5]. It exhibits a distinct tryptic cleavage specificity when tried on the oxidized B-chain of insulin and is inhibited by all natural and synthetic trypsin inhibitors including TLCK. It is a serine protease and possesses the sequence –Asp–Ser–Gly– around the active centre serine residue[6]. In addition, extended immunological studies have been carried out on the crayfish trypsins of three species which revealed that they do occur as isoenzymes varying in number and electrophoretic mobility[7].

Table 1. AMINO-ACID COMPOSITION OF TRYPSINS

	Invertebrate	Vertebrate	
	Crayfish	Dogfish[3]	Bovine[11,12]
Lysine	5	5	14
Histidine	5	8	3
Arginine	2	7	2
Aspartic acid	30	24	22
Threonine	15*	7	10
Serine	17*	17	33
Glutamic acid	21	16	14
Proline	10	10	9
Glycine	28	28	25
Alanine	16	16	14
Half-cystine	6†	12	12
Valine	18‡	17	17
Methionine	2	8	2
Isoleucine	15‡	14	15
Leucine	16	15	14
Tyrosine	11	12	10
Phenylalanine	7	1	3
Tryptophan	3§	5	4
NH_3‖	17		
No. of residues	227	222	223

* Calculated from 20 h and 70 h hydrolysates by first order approximation to zero time.

† Determined after performic acid oxidation[9].

‡ Values for 70 h hydrolysis.

§ Determined spectrophotometrically[10].

‖ An approximative value for the amide content of crayfish trypsin was derived from the 20 h ammonia value by subtraction of the ammonia peak from a blank hydrolysate, the ammonia being the result of the decomposition of serine and threonine.

Purified *Astacus leptodactylus* trypsin is composed of two closely related bands which are both active against BAEE. They were separated in a final purification step by disc electrophoresis[8] and the amino-acid content of each component was analysed quantitatively. Four analyses of component I (which moved fastest to the anode) were done from 20 h and 70 h acid hydrolysates at each time interval. An analysis of bovine trypsin which was run for comparison in the same conditions gave correct values. The examination of component II did not reveal significant differences in amino-acid composition. This is in concordance with our observation that both components are cross-reacting immunologically[7].

Crayfish trypsin was shown to have 227 amino-acid residues (dogfish and bovine trypsin have 222 and 223 residues respectively). This accounts for a molecular weight of 24,060.

From the amino-acid composition of the three trypsins it may be concluded that the invertebrate crayfish trypsin is homologous in primary structure to vertebrate trypsin. The proportions of proline, alanine, valine, isoleucine, leucine and tyrosine are essentially the same in all three trypsins. On the other hand, the high lysine and serine content of bovine trypsin is not shared by the two other trypsins. Crayfish and dogfish trypsin likewise exhibit only a third of the lysine and a half of the serine content of bovine trypsin. In dogfish trypsin the histidine, arginine and especially the methionine values are increased, whereas the other two enzymes are similar in this respect. This may reflect specific evolutionary features of dogfish trypsin, as well as the increase in lysine and serine content of bovine trypsin. Outstanding differences of this kind were not found in crayfish trypsin.

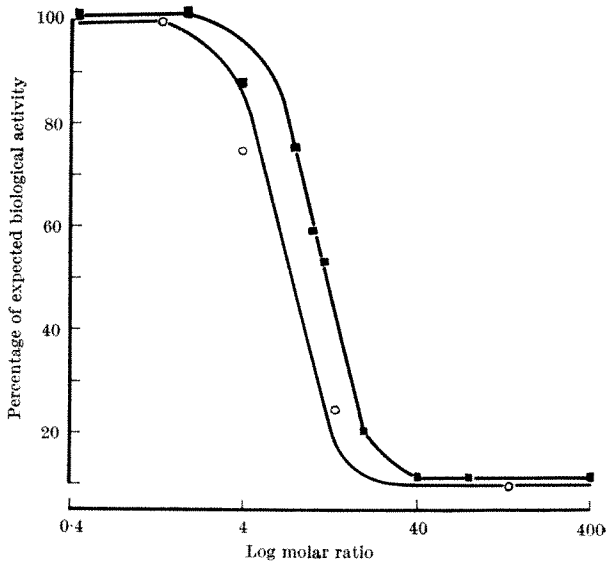
Iodination and the Biological Activity of Gastrin

RADIOIODINATED polypeptide hormones are widely used as tracers for both radioimmunoassay and *in vivo* metabolic studies. The process of iodination may induce gross chemical changes which are detectable by physico-chemical techniques, but such techniques may not reveal more subtle changes reflected only in decreased biological activity. Such a situation arises with gastrin, in which iodination of the synthetic hormone by the chloramine-T method[1] results in almost total loss of biological activity. This is due to oxidation of the methionyl residue at position 15, which is in the biologically active C-terminal tetrapeptide sequence, and can be prevented by modifying the iodination procedure. The resulting iodinated gastrin has full biological activity, is labelled to the same specific activity as in the original method, and has an increased affinity for antibodies to the hormone.

Synthetic human gastrin I (SHG; Pyr-Glu-Gly-Pro-Try-Met-$(Glu)_5$-Ala-Tyr-Gly-Try-Met-Asp-PheNH_2) and pentagastrin (ICI 50, 123; *t*-butyloxycarbonyl-β-Ala-Try-Met-Asp-PheNH_2) were obtained from ICI Ltd, Alderley Park, Cheshire. SHG was iodinated either with carrier-free ^{125}I (Radiochemical Centre, Amersham) or with ^{127}I using the chloramine-T method, as modified by McGuigan[2]. Iodinated SHG was separated from unreacted iodide on a 1 × 15 cm column of 'Sephadex G-10'.



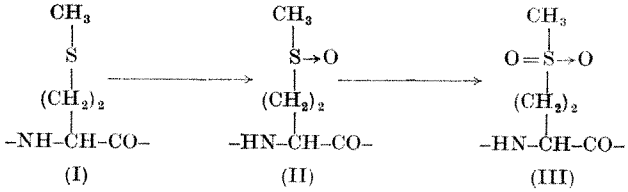


Fig. 1. The biological activity of synthetic human gastrin I (■) and pentagastrin (○) after treatment with chloramine-T. 1 μg quantities of SHG and pentagastrin were treated with increasing amounts of chloramine-T as described in the text. The biological activity, measured by bioassay in the anaesthetized rat, is expressed as a percentage of the activity of the same amount of untreated SHG or PG. On the abscissa is plotted the logarithm of the molar ratio of chloramine-T to SHG and PG. In the amounts used in the radioiodination of SHG, the log molar ratio of chloramine-T to SHG is 140.

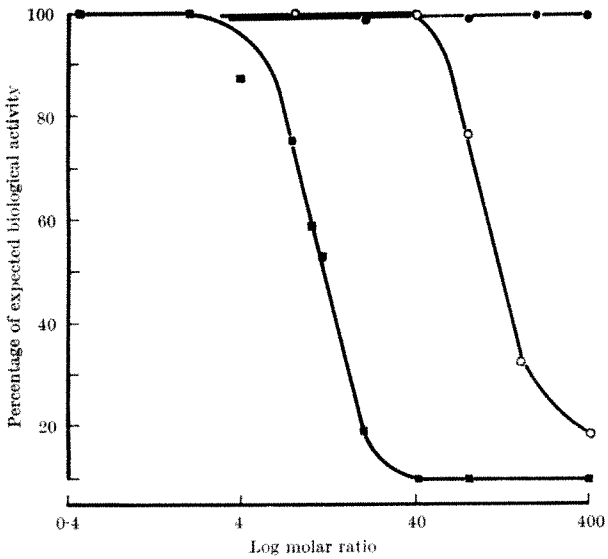
The biological activity of SHG and pentagastrin samples was measured by bioassay in the anaesthetized rat[3].

Iodination with either ^{125}I or ^{127}I reduced the biological activity of SHG to less than 10 per cent of its original value. This was not due to the introduction of iodine atoms into the molecule because a similar effect was produced on exposure of SHG or pentagastrin to chloramine-T and metabisulphite in the absence of iodide.

To investigate this, varying amounts of chloramine-T (0·05–50 μg) were added to 1 μg SHG followed, after exactly 1 min, by sodium metabisulphite (five times the weight of chloramine-T). The same buffer and volumes were used as for iodination and the reaction mixtures were again fractionated on 'Sephadex G-10' columns. The first 10 ml. of the eluates were collected as pools. Similar experiments were carried out with the substitution of an equimolar amount of pentagastrin for SHG. The biological potencies of SHG and pentagastrin were reduced to similar extents (Fig. 1), and so we concluded that one of the reagents used in the iodination procedure was exerting an effect on the C-terminal tetrapeptide sequence which the peptides have in common.

Morley[4] has shown that the methionyl residue (I) at position 15 in the gastrin molecule is readily oxidized to the sulphoxide (II) and sulphone (III) derivatives

This process leads to loss of biological activity. Chloramine-T is an oxidizing agent and is present in considerable excess in the iodination reaction mixture, so it seemed possible that the observed effects on SHG and pentagastrin were the result of oxidation of the methionyl side-chain sulphur atom by chloramine-T. We confirmed that such an oxidation reaction occurred by amino-acid analysis of a sample of SHG exposed to chloramine-T. Methionine was absent and an equivalent amount of



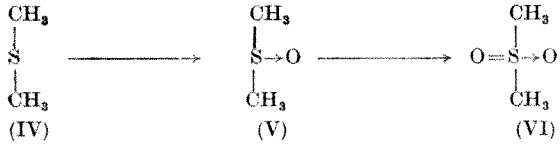


Fig. 2. The protection of SHG by dimethyl sulphoxide (DMSO) from oxidation by chloramine-T. ○, Biological activity of 1 μg SHG after treatment with varying amounts of chloramine-T in the presence of a 700 molar excess of DMSO with respect to SHG (25 μl. DMSO/μg SHG); ●, results obtained when DMSO was present in a 1,400 molar excess (50 μl. DMSO/μg SHG); ■, curve obtained when no DMSO was present, shown for comparison. The scales are the same as in Fig. 1.

methionine-S-oxide was present, corresponding to a methionine-S-oxide: leucine standard ratio of 1 : 1.

We therefore examined methods for protection of the methionyl residue from the oxidative action of chloramine-T, by use of a "scavenger" which would compete with methionine for chloramine-T. Dimethyl sulphoxide (DMSO; V), a stable, relatively non-volatile liquid, miscible with water, was selected for trial. This is the intermediate in the oxidation of dimethyl sulphide (IV) to dimethyl sulphone (VI)

When 25 μl./μg of SHG was incorporated in the reaction mixture (without iodide), the curve showing reduction of biological activity was shifted to the right; with 50 μl./μg of SHG, full biological activity was observed at all concentrations of chloramine-T tested (Fig. 2). The inclusion of DMSO at the latter concentration in iodinations of SHG with ^{125}I yielded a radioiodinated peptide with full biological activity and without reduction of specific activity.

Antiserum to SHG (residues 2–17) was produced in rabbits by immunization with the peptide conjugated to bovine serum albumin by carbodiimide condensation[5]. ^{125}I-SHG prepared in the presence and absence of DMSO was tested for its ability to react with this antiserum, using a double antibody technique. The binding of the biologically active ^{125}I-SHG was consistently greater than that obtained with ^{125}I-SHG prepared in the absence of DMSO. In a typical experiment, the percentage of binding was increased from 34 to 58. Gastrin antibodies were raised against the native hormone so it is not surprising that the antibody binding of biologically active ^{125}I-SHG was significantly greater than that of the inactive ^{125}I-SHG. This observation supports McGuigan's suggestion[6] that one of the principal antigenic determinant sites of the gastrin molecule is the C-terminal tetrapeptide sequence.

The procedure we have developed for the protection of gastrin during radioiodination may be applicable to other polypeptide hormones, and may have significance for both radioimmunoassay and *in vivo* tracer studies.

Anthropological Significance of Gamma Globulin (Gm and Inv) Antigens in Bougainville Island, Melanesia

The known distribution patterns of Gm and Inv antigens reflect remarkably the accepted historical relationships of different human groups[1]. In this communication we report new developments which modify the previously recognized pattern of Gm and Inv variation in Melanesian populations and its implications for Melanesian prehistory.

The linguistic distinction contrasting the Melanesian (hereafter MN) with the residual category of non-Austronesian languages (hereafter NAN) forms the most pervasive dichotomy throughout Melanesia. Most of the perhaps 500 NAN languages are located in the interior of New Guinea, although some are found on islands near by. While it has proved difficult to establish clear relations for languages within the NAN group, the sketchy archaeological record from Melanesia suggests that the distributions of some artefacts roughly agree with the total extent of NAN languages. At least we can assume that human populations have occupied New Guinea for the past 20,000 years[2].

The later advent of MN languages in the area has been equated by some workers with a widespread pottery tradition, the so-called Lapita style, which is dated at about 750 BC in the Philippines and about 500 BC in Tonga. These languages have been described as being quite diverse while having an underlying structural uniformity. There are three theories concerning their origins: (1) (emphasizing the similarities) they were brought into Melanesia from Indonesia by groups belonging to the same stock and diversified in place; (2) (emphasizing the diversities) they were brought in by groups from different parts of Indonesia, and pidginized varieties of these languages developed at the sites of the new habitation, so that the grammar represents a simplified Indonesian, while the vocabulary consists of a core of simplified Indonesian and a large number of less basic words derived from indigenous (NAN) languages; (3) (attributing all the diversity to a long period of development in isolation) they were a local development, perhaps representing the earliest branching of the Austronesian stock[3].

Giles *et al.*[4] were able to distinguish clearly between MN speakers in the Markham Valley, New Guinea, and NAN speakers there and on nearby Bougainville Island by the almost total lack of Gm (2) individuals among the

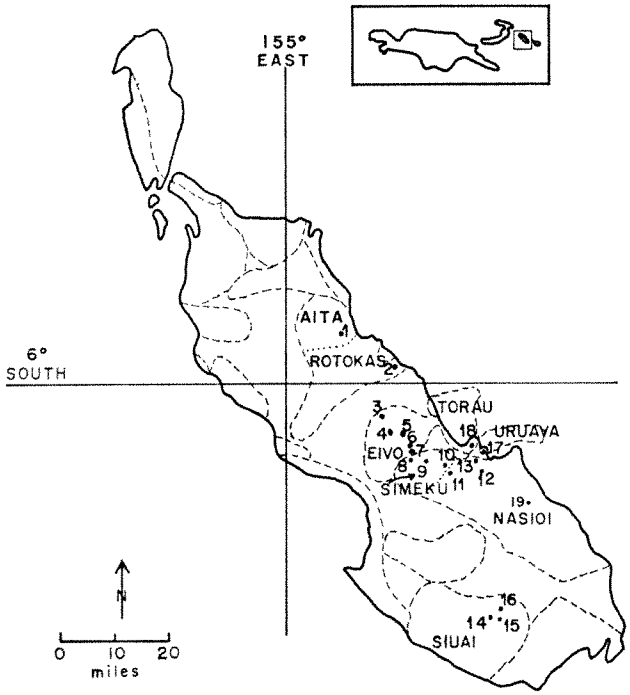

Fig. 1. Geographical location of the sampled villages on Bougainville Island. - - - -, Language boundaries; · · · ·, relevant dialect boundaries.

MN speakers, as opposed to their presence in low to medium frequencies among the NAN groups. These MN groups also had consistently lower frequencies of Gm (1) and higher frequencies of Gm (5) than the NAN groups. It seemed, too, that the MN speakers of the Markham paralleled south-east Asians in Gm phenogroup frequencies more closely than did the NAN peoples. Giles *et al.* concluded: "The Gm frequencies imply the existence of two populations with origins separate in time or space. One of these populations, the MN speakers, appears closely related to south-east Asians and not an autochthonous Melanesian differentiation"[4]. This amounts to a refutation of the third hypothesis of the origin of MN languages.

Steinberg[5] later retested 836 of the Gm (1, 5) positive samples from the Markham Valley for Gm (3), Gm (13), and Gm (14) and found that all were Gm (13) and Gm (14) positive, but that only 38·5 per cent of these were Gm (3) positive in the NAN group, while 53·2 per cent were positive in the MN group. The data indicate the presence of a $Gm^{1,5,13,14}$ phenogroup which had not been postulated for any of the few other series from Asia or Oceania. In terms of the *Gm* phenogroup frequencies, the MN speakers in the Markham could possibly be interpreted as hybrids of indigenous NAN New Guinea groups having $Gm^{1,5,13,14}$ and of some outside stock lacking that phenogroup.

Here we examine the possibility that this linguistically related biological division on New Guinea holds for NAN and MN groups on Bougainville Island as well[6]. There are seventeen mutually unintelligible languages indigenous to the island[7], of which six languages and two dialects were represented in this study (Figs. 1 and 2). The eighteen villages covered in the survey, and the additional group previously tested by Giles *et al.*[4], are all located within a very small area, so that environmental differences are minimal. An effort was made to collect blood from all residents over 2½ years old. Serum samples were typed for Gm and Inv factors by established methods[8] in the same laboratory which participated in the Markham Valley study, and tests for the Gm (3), Gm (13), and Gm (14) antigens were added to the earlier results. (All samples were tested for Gm (1) (Wils./251); Gm (2) (Tay./Ham.); Gm (3) (E.W./Jac.), (Joh./3196); Gm (5) (Dra./31369); Gm (6) (Deb./War.); Gm (13) (Tho./21369) Gm (14) (Bur./21369); and Inv (1) (Mak./Roe.). The entries in the brackets show the reagents used; the antibody to immunoglobin is shown first, and the antibody to D second.)

Table 1. Gm PHENOTYPE AND PHENOGROUP FREQUENCIES BY VILLAGE

18. Rorovana	243	1	0	14	228	0·050	0·029	0·920

All samples were tested for Gm (1), Gm (2), Gm (3), Gm (5), Gm (6), Gm (13) and Gm (14). Only the positive reactions are recorded.
* Sampled by Giles *et al.*[4].

The Gm results are extremely heterogeneous (Table 1) There are, however, no consistent distinctions in *Gm* phenogroups or phenogroup frequencies between the MN and NAN villages. Note that while 351 MN speakers were typed, these were taken from only two villages which may be distinct from MN speakers in northern Bougainville, for the founders of group 18 emigrated from a southern off-shore island only 100 years ago and the founders of group 17 sometime before that.

All typed Bougainvillians who were Gm (1, 5, 13, 14 were also Gm (3) positive, that is, the $Gm^{1,5,13,14}$ phenogroup is absent. This same constellation holds for the other circum-Pacific groups that have been surveyed thus far for these antigens[5], with the aforementioned exception of the Markham Valley New Guineans.

Bougainvillian Inv frequencies (Table 2) from a clear step cline from north to south, the first such cline so far noted. The most pronounced shift in frequency occurs among the Simeku (8–10), the transitional population between the northern and southern NAN groups. The Inv frequency for village 1 is higher than any previously reported, being approached only by a few South American Indian tribes[9]. The lowest frequencies from the current series belong to the 2 MN villages which, because of their recent migration from the south, may be viewed as a simple continuation of the cline. In very sharp contrast New Guineans from the Markham Valley[4] uniformly have among the lowest Inv^{1} frequencies of any known group

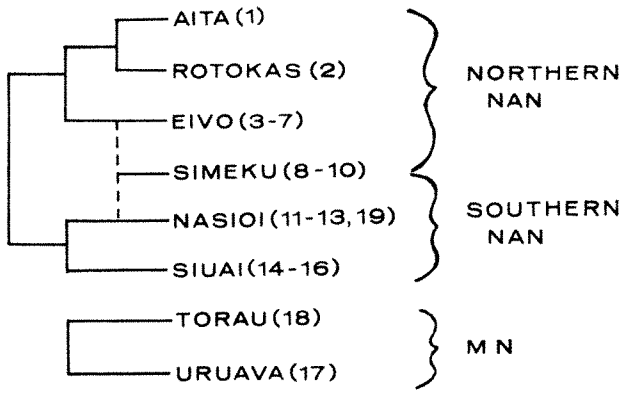

Fig. 2. The relationships of the language groups sampled from Bougainville in terms of shared cognate percentages reported in ref. 7.

Table 2. Inv OBSERVED PHENOTYPES AND PHENOGROUP FREQUENCIES BY VILLAGE

* Samples by Giles *et al.*[4].

The emerging pattern of Gm and Inv distributions reflects the extraordinary diversity of the NAN speaking groups and the primary importance of the local geographic region as the unit of isolation. The biological separation of the two linguistic stocks within the Markham Valley remains clear, but its extension to Bougainville NAN and MN speakers is not, nor is the affinity of MN speakers with peoples in south-east Asia. A linguistically related division in Inv frequencies does exist within Bougainville, but this concerns the two divisions of NAN which presumably diversified in place.

These data, then, cannot be said to rule out any of the three hypotheses concerning the origins of the MN languages. If linguistic affinities do reflect population movements in this area, we believe that a model which allows for significant interbreeding of neighbouring MN and NAN groups over time and which stresses isolation by distance is required to explain the data. Such interbreeding over short distances has obliterated most of the clear biological distinctions which may once have existed between the NAN and MN speakers within Melanesia, but such a process evidently has not been completed in New Guinea.

Membrane-complement Fixation Test for Hepatitis Associated Antigen

We describe here an analytical test for hepatitis associated antigen (HAA)[1], originally called the Australia antigen[2] or S.H. antigen[3], that combines the advantages of the Ouchterlony technique[3] in its simplicity, the complement fixation technique[4] in its sensitivity, and the electrophoretic technique[5] in its rapidity and accuracy.

Antigen was detected in seventy-eight of one hundred coded sera obtained from patients with acute viral hepatitis within 1 month after onset of the disease. The test was based on the technique previously described[5] in which immunoprecipitation was promoted by the electrophoretic movement of antigen through a preformed microporous cellulose acetate membrane saturated with antibody, and which detected 38 per cent HAA positive reactions in unconcentrated sera. To increase the sensitivity of the original test, it was reasoned that the standard complement fixation procedure was more sensitive as it detected soluble antigen-antibody complexes that washed out of the cellulose acetate membrane in the electrophoretic technique and out of the agar in the immunodiffusion technique. After the electrophoretic movement of HAA into the antibody saturated cellulose acetate membrane, complement was therefore added to the unwashed reaction medium. The complement probably fixed to the soluble and insoluble immune complexes "locking" them in the membrane. An antibody made to the serum of the species from which the complement was derived was added to the membrane after a brief washing of the membrane to elute unreacted proteins. After incubation and washing, the resulting immunoprecipitates were stained. The entire procedure took $2\frac{3}{4}$ h with constant current supplies and $1\frac{1}{2}$ h with the application of pulsed constant power (Ortec).

A microporous cellulose acetate membrane (95 mm × 75 mm × 0·01 mm thick, Millipore Filter Corporation or Gelman Instrument Company) was saturated with 1 ml. of a dilution of anti-HAA antiserum (1 : 16 was used in these studies) obtained by plasmaphoresis with informed consent from a haemophilic patient. The membrane was sandwiched between a top lucite template and a 'Parafilm' covered neoprene base bolted together by a torque wrench preset at 5×10^6 dyne cm.

Unknown serum samples (2 μl. each) were applied to conical wells found in the template open to the membrane below. Both HAA positive and HAA negative sera were included as controls in each test.

Barbital buffer, 0·05 M, *p*H 8·2 was used for dilution of the antibody and for soaking sponge wicks connecting the membrane to the electrophoresis chamber. 6 mA of constant current (approximately 250 V) were applied for 2 h; 18 to 20 mA of pulsed constant power gave comparable results in 30 min.

At the end of the electrophoresis, the membrane was placed directly in a plastic container and gently overlaid with a 1 : 400 dilution of guinea-pig complement[6] and was incubated at room temperatures for 15 min with intermittent shaking. The membrane was then washed with buffered saline for 15 min to remove unreacted human serum proteins and unreacted guinea-pig complement. The washed membrane was placed in a 1 : 4 dilution of rabbit anti guinea-pig serum for 15 min at room temperatures; it was then washed and the precipitates were stained ('Ponceau S' dye fixative followed by acetic acid clearance and 'Nigrosin' counterstain is routinely used in our laboratory).

The presence of rocket-shaped immunoprecipitates showed positive HAA antigenaemia. The antigen was measured using the immunoprecipitate planar area[7]. Fig. 1 shows the results of testing five sera previously HAA negative by either the Ouchterlony or electrophoretic techniques, and positive and negative control sera. The control sera were placed at 4° C for 1 week before testing

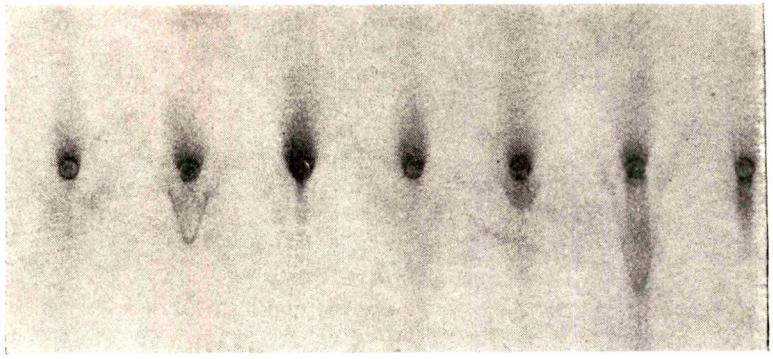

Fig. 1. Electrophoretic immunoprecipitates (or negative reactions) (reading from left to right), associated with acute viral hepatitis (samples 1, 2, 3, 4, 5), HAA positive control (sample 6), HAA negative control (sample 7). Positive samples are those with rocket-shaped immunoprecipitates pointed downwards towards the anode (samples 1, 2, 4, 5, 6).

to allow prote in-protein interactions making them more comparable with patient sera subjected to storage or adverse shipping conditions. Positive HAA reactions were now found in four of the five patient sera. Rocket-shaped immunoprecipitates were clearly distinguishable from the aggregated proteins found in the controls (which are not usually seen in fresh or frozen sera).

Thus the addition of complement reveals more of the soluble and insoluble immunocomplexes found in membrane media.

Cell Mediated Immunity induced *in Vitro*

A CELLULAR immune response to antigenic stimulation is frequently accompanied by a humoral immune response. This conjugal behaviour has complicated an understanding of the specific steps of a cellular immune response. Humoral immunity is easily measured apart from cellular immunity. Specific measurement of cellular immunity, however, is complicated by the ability of some cells in lymphoid organs to produce both complement[1] and antibody[2]. Brunner *et al.*[3] have introduced a ^{51}Cr release technique for measuring cellular immunity, and our modifications[4] have increased the sensitivity of the procedure and the certainty that cellular immunity is being detected. We have now used this method to detect the *in vitro* induction of cellular immunity.

Normal mouse spleen cells (2×10^7/dish were sensitized by incubation for five day with allogeneic lymphoid tumour cell (1×10^4/dish) according to the procedure o Mishell and Dutton[5]. Cellular immun activity was measured apart from humora immunity by incubating replicate culture of the sensitized cells (5×10^6/dish) for 3 h with ^{51}Cr-labelled target cells (5×10^4/dish in the presence of carrageenan (200 μg/ml.) Between sensitization and measurement o cellular immunity, spleen cells were washe once by centrifugation and suspended i fresh media. Details of the cellular immun ity assay are described elsewhere[4].

The cellular immune response elicited b *in vitro* immunization was specific for th sensitizing antigen (Table 1*a*). Non-sensitize spleen cells were not reactive. Sensitize spleen cells did not react with target cell unrelated to the sensitizing cells. Sensitized spleen cell reacted not only with the sensitizing tumour cells bu also with normal lymphoid cells syngeneic with th sensitizing cells ((Table 1*b*). The immune cells therefor seem to recognize and react against histocompatibilit antigens. The effectiveness of the *in vitro* immunization i apparent from the similarity of the *in vitro* and *in viv* induced responses (Table 1*c*). If cellular immune activit were expressed as a function of viable cells instead c total cells (as is done here), the comparison would be eve closer. The viability (dye exclusion) of freshly explante spleen cells was consistently higher than 90 per cent spleen cells cultured *in vitro* for five days, however, ha an average viability of 67 per cent.

§ Syngeneic with DBA/2 ($H2^d$).

The immune response measured here seems to be ce mediated. A complement C′ inhibitor, carrageenan, wa included in the assay media at a concentration whic blocks C′ dependent antibody activity[4,6]. Also, r soluble toxins including C′ dependent antibody could b detected in cell-free media collected after both the 5 da sensitization period and the 3 h assay period (Table 1 These findings are in agreement with data obtained usi *in vivo* sensitized cells[4].

Humoral immune responses have been induced *in vit* against a variety of antigens. In some reports[5,7–10], the responses *in vitro* have been equivalent to those found *vivo* in terms of the appearance after exposure to antig and the height of the immune reaction. Successful *vitro* immunization has facilitated investigation of th afferent limb of the humoral immune response by the u of cell fractionation[11–16], selective irradiation[17] ar

addition of specific antibody[18] or tolerance inducing antigen[10]. Antimetabolites have been used in these systems to study the dependence of humoral antibody formation on cell division and biosynthesis of RNA and protein[19,20].

Similar knowledge about the details of cellular immune responses is lacking largely because appropriate systems were not available for investigation. Systems that will contribute to such studies have been reported[21,22] in which *in vitro* sensitized rat lymphocytes were capable of destroying mouse embryo target cells in tissue culture. Simmons and Manson[23] have also been able to sensitize mouse spleen cells *in vitro* with an allogeneic membrane preparation. The sensitized cells were able to interfere with the immune function of cells syngeneic with the sensitizing antigen. Recently Häyry and Defendi[24] have reported *in vitro* induction of mouse cellular immunity to allografts in which both the sensitization and effector phases were successfully monitored.

In this study, the *in vitro* induction of immunity against allogeneic histocompatibility antigens has been demonstrated by a rapid, quantitative system. The immune response is specifically cellular and the intensity of this response was equivalent to that found after *in vivo* sensitization.

We thank Dr Robert Mishell for discussions concerning *in vitro* immunization and Dr John Fahey for advice.

Mixed Lymphocyte Cultures and HL-A Identity in Unrelated Subjects

INVESTIGATIONS using highly selected lymphocytotoxic and complement-fixing platelet antibodies have made it possible to define a considerable number of antigens belonging to the HL-A system. These antisera are determined by genetic information belonging to a still unknown number of closely linked loci, subloci or mutational sites. Most of the known HL-A antigens seem to belong to two series, 'LA' and '4', each of which contains a number of mutually exclusive genes and corresponding antigens. An ever increasing number of antigens are being identified[1–5]. The various genes and corresponding antigens, which can be determined, are given in Table 1.

Table 1. FREQUENCIES OF THE '4' AND 'LA' GENES

Determinant	Gene frequencies Danes	Norwegians

"0"	0·1402	0·1366

A maximum of four different HL-A genotypes is possible in siblings, provided that crossing-over within the HL-A locus has not occurred. It is most likely therefore that siblings are truly identical with respect to HL-A, if they give the same typing results, even when all their HL-A antigens cannot be demonstrated. It has been shown unequivocally that cells from HL-A identical siblings are not stimulated in mixed lymphocyte cultures, by contrast with mixed lymphocyte cultures for donors not identical with respect to HL-A, where stimulation always occurs[6]. This implies that all antigens of importance for stimulation in mixed lymphocyte cultures must be determined by genetic information identical to or closely linked to that of the 'LA' and '4' subloci. If the HL-A system consisted only of the two subloci mentioned, any individual should have a maximum of four HL-A antigens, and the absence of stimulation in mixed lymphocyte cultures should be evident for unrelated cell donors having the same four antigens exactly as for HL-A identical siblings.

Mixed lymphocyte cultures for four pairs of unrelated cell donors identical with respect to four well defined HL-A antigens were tested, and we here present the results. A skin graft was, moreover, performed between members of one of the pairs. Pairs of individuals carrying identical HL-A antigens were sought using a previously described data retrieval system (KH: not marginal punch cards)[1] and looking only for subjects having four well-defined HL-A antigens (and genes): two 'LA' and two '4' antigens. This excluded the possibility of uncertainty arising from as yet undetectable antigens belonging to these two subloci. The control subjects were selected without their HL-A type being known but they were typed retrospectively.

HL-A typing was performed as previously described using cytotoxicity and complement fixation with lymphocytes and platelets as antigens, respectively[7,8]. Lymphocytes from the test subjects were typed both in Copenhagen and in Århus. In addition to lymphocytotoxic

sera of well defined specificity, a varying number of multispecific sera were also used. In some cases, typing of the families of the test subjects allowed us to deduce the HL-A genotypes.

Mixed lymphocyte cultures were prepared as previously described[9]. Cultures contained 1×10^6 responding lymphocytes and 1×10^6 stimulating lymphocytes, rendered incapable of participating in the response by pretreatment with mitomycin C (Sigma). Culture volumes were 2 ml. and the medium consisted of 'TC 199' (Glaxo) with 30 per cent 'Intradex' (Glaxo), supplemented with 30 per cent serum pool from all the cell donors included in the experiment. All cultures were harvested in duplicate. In one experiment, cultures were harvested at 24 h intervals from day 2 to day 6, whereas the others were harvested 90 h after the preparation of the cultures.

After incubation for 4 h with 0·2 μCi ^{14}C-thymidine (specific activity 56·2 μCi/mmole; Radiochemical Centre, Amersham), cells were collected on glass fibre filters and prepared for liquid scintillation counting as described previously[10]. All samples were counted in a Packard 'Tri-Carb' liquid scintillation counter, and the results were expressed as background c.p.m. per 1×10^6 responding lymphocytes of the initial cultures.

A full thickness skin graft was performed as described by Rapaport[11].

Table 2. SEX, AGE, BLOOD GROUPS AND HL-A TYPES

Expt. No.	Subject	Sex	Age	Blood group	HL-A type
1	T. A.	M	34	A	2, 5/3, 7
	A. L.	F	33	O	2, 3, 5, 7
	K. K. (control)	F	22	B	2, 3, 7, FJH
	A. A.	F	41	O	1, 8/3, 7
2	F. J.	M	47	O	1, 3, 7, 8
	L. K. (control)	F	37	B	1, 8/1, 4A2*
	R. L.	F	56	O	3, 7/2, R*
3	M. C.	M	37	A	3, 7/2, R*
	R. K. (control)	M	27	A	2, Li, 5, BB
	R. E.	F	26	O	2, 7, 9, BB
4	R. J.	F	28	O	2, 7, 9, BB
	K. O. (control)	M	34	AB	2, 3, 12, 407*

Four experiments were performed. The results of the HL-A and blood grouping are given in Table 2. It can be seen that the four pairs each carried identical antigens from the 'LA' and '4' series, whereas the control subjects were always different from the test subjects. It may be added that cells from each of the four pairs exhibited identical reaction patterns when tested with a varying number of multispecific antibodies.

Results of the mixed lymphocyte culture tests are given in Table 3. A and B refer to the two cell donors carrying the same four well defined HL-A antigens; K refers to unrelated cell donors; A + Bm refer to a mixture of A leucocytes as responding cells and mitomycin-treated lymphocytes from B as stimulating cells.

Fig. 1 illustrates an experiment (No. 1) in which the incorporation of thymidine was followed during the first 5–6 days of culture. Incorporation still increased after day 4, but we harvested routinely after 90 h because it has been shown previously that the most reliable quantitation is obtained by measuring the thymidine uptake early in the culture period[12]. In all cases mixtures of unrelated cell donors with identical 'LA' and '4' types caused significantly higher stimulation than the unstimulated controls.

Fig. 2 shows the ratio between mixed cultures and controls in these experiments as compared with four experiments according to the same scheme but using HL-A identical siblings as cell donors. Maximum stimulation in mixtures from HL-A identical siblings was only twice the control, whereas the stimulation in mixtures from 'LA' and '4' identical cell donors was 2·2–13 times the controls. It is evident from Table 2 that in all experiments except No. 4, the stimulation obtained between the test subjects was lower than in the mixtures with mitomycin-treated cells from the control subjects; the probability that this arises by chance is $P = 0{\cdot}035$; the lowest stimulation was in experiment No. 2, mixture Am + B. Skin grafting was performed from A to B and the skin survived for 18 days.

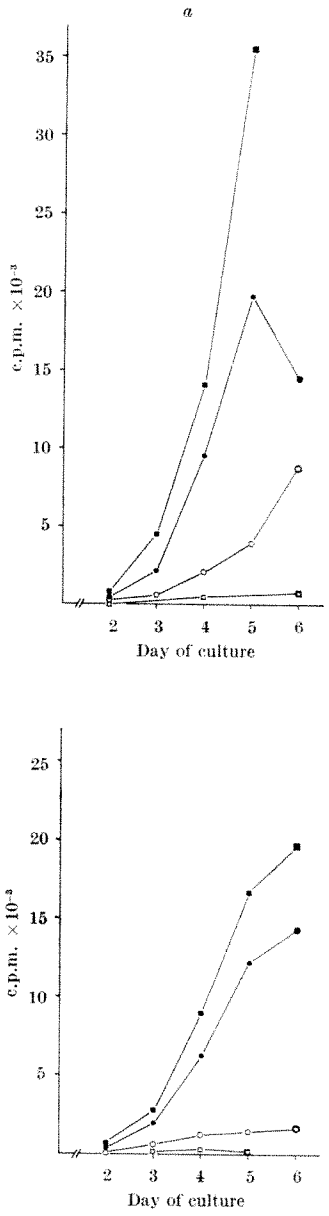

Fig. 1*a* and *b*. Experiment 1. A, L and K unrelated. A and L typing identical; HL-A2, 3, 5 and 7. *a*: ○, A + Lm; ●, A + Km; ■, K + Lm; □, A + Am. *b*: ○, L + Am; ●, L + Km; ■, K + Am; □, L + Lm.

Because each of the four pairs carried two different antigens from each of the series, 'LA' and '4', they could not possess hitherto unknown alleles from these two series. In other words, they carried pair-wise only the same antigens from the 'LA' and '4' series. The experiments showed clearly that the leucocytes from these pairs were able to stimulate each other in mixed lymphocyte culture tests although the stimulation was sometimes very low (Table 2, Fig. 1). This observation may be explained in three different ways: first, the stimulation may be attributed to the presence within the pairs of different but as yet unknown HL-A antigens controlled by genes on one or more loci or sites linked to the 'LA' and '4' subloci. Second, some of the antigens recognized in these subjects may be heterogeneous; that is, they may not be completely identical in different individuals. Third, possible genotypic differences in these phenotypically

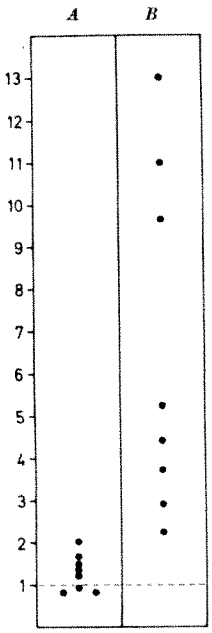

Fig. 2. Ratio between mixed cultures and controls. *A*, HL-A identical siblings; *B*, unrelated persons typing identical for four HL-A antigens.

identical pairs may be responsible for the stimulation. The stimulation observed in experiment 3, however, is incompatible with the third possibility, for RL and MC were genotypically identical. The second explanation implies that the antibodies used for typing are not monospecific, which does not seem likely for experiments 1 and 2 which only involved some of the most well defined HL-A antigens. Nevertheless, it seems worth noting that the demonstration of cross-reactivity between some HL-A antigens[13] has made it very difficult to define monospecific antibodies. We feel the first explanation—the existence of one or more mutational sites in addition to 'LA' and '4'—is the most likely. It is supported by the recent observation of an antibody reacting with an antigen which is apparently controlled by a gene not belonging to the 'LA' and '4' series[14].

Thus we have not succeeded, using 'LA' and '4' typing, in selecting unrelated pairs which did not stimulate each other in mixed lymphocyte culture. But Table 2 seems to demonstrate that the degree of selection was sufficient in all but one case to ensure a stimulation in mixed lymphocyte culture inferior to that elicited by cells from a randomly selected, unrelated individual. Fig. 1 illustrates that the degree of compatibility obtained between the test subjects in this experiment was much better than with the control subject.

Table 3. RESULTS OF THE MIXED LYMPHOCYTE CULTURE EXPERIMENTS

Expt. No.	1	2	3	4
A:	TA	AA	RL	RE
B:	AL	FJ	MC	RJ
K:	KK	LK	PK	KO
A + Bm	2,071	2,549	1,767	2,907
B + Am	1,206	924	715	2,557
A + Km	9,598	3,419	2,537	1,404
B + Km	6,280	2,312	4,162	3,714
K + Am	9,021	1,618	2,913	2,148
K + Bm	14,133	2,739	3,689	3,630
A + Am	473	266	331	219
B + Bm	325	411	246	236
K + Km	546	612	123	216
Am + Km	124	119	102	193
Bm + Km	182	82	67	63

In experiment 2, the AA cells only slightly stimulated the FJ cells, and this good compatibility was confirmed by the survival of an AA skin graft on FJ for 18 days. By comparison, skin grafts exchanged between ABO-compatible, unrelated individuals survive for $12{\cdot}1 \pm 1{\cdot}55$ (s.d.) and for $20{\cdot}0 \pm 4{\cdot}23$ (s.d.) days between HL-A identical siblings[15]. In experiment 4, however, the control cells stimulated the RE leucocytes less than the RJ cells, in spite of the fact that the control cells were incompatible for HL-A3, 12 and a new antigen from the '4' series, 407*, whereas no incompatibility could be demonstrated for the RJ cells. When repeated, this experiment revealed a higher stimulation in the mixtures A + Km and B + Km than in those of A and Bm and B + Am, respectively. The earlier results may have been subject to technical errors, but could also be explained by the presence in RJ cells of as yet unrecognized antigens capable of causing more stimulation than the HL-A3, 12 and 407* antigens. If this is so, and if the degree of stimulation in mixed lymphocyte culture parallels the strength of the incompatible HL-A antigens, these unknown antigens may be strong transplantation antigens. This is, however, supported neither by the rather close correlation between the match grade for 'LA' and '4' antigens and the results of kidney transplantations[2], nor by the observation that it seems to be difficult to produce cytotoxic antibodies against HL-A antigens not belonging to the 'LA' and '4' series. J. J. van Rood and V. P. Eijsvoogel have recently published the results of similar investigations[16].

In Vitro Sensitization of Mouse Peritoneal Mast Cells with Reaginic Antibody

EXPERIMENTAL models for the study of anaphylaxis usually make use either of the whole animal or of isolated organs. Although such complex systems have many advantages in that they reproduce the clinical conditions, it is obvious that their complexity makes it difficult to analyse separately the various phases of the anaphylactic reaction. The use of isolated cell systems would be better suited to study, for instance, the interaction between cells, antibody and antigen.

Techniques using isolated cells have been recently developed for human leucocytes[1], rat[2] and mouse[3,4] peritoneal mast cells. Two classes of anaphylactic antibodies in the mouse have been described. One of them, designated γ_1, is a non-complement fixing 7S immunoglobulin[5]; the other is a thermolabile, reaginic type of antibody[6-9], probably similar to human IgE. Both antibodies act on the mast cell, but their mechanisms of action are different. Thus the reagin fixes firmly to the mast cells and cannot be washed out[7-9], while γ_1 does not fix to the cells and induces cell damage through the formation of a soluble complex with antigen[3,10,11].

In vitro passive sensitization with γ_1 antibody is readily achieved[3,10,11], but passive sensitization with reaginic antibody has been obtained only *in vivo*[8]. The possibility of performing *in vitro* fixation of reaginic antibody on the peritoneal mast cells of mouse is of the greatest interest for the study of the mechanism of sensitization. Using purified antibody preparations we have now succeeded in passively sensitizing isolated mast cells with reaginic antibody.

Antibody was produced in a strain of Swiss mice, random-bred for many years in a closed colony at the Institute Oswaldo Cruz, Rio de Janeiro, Brazil, and inbred in our laboratory. In order to obtain sizable quantities of antibody, ascitic fluid was induced[12] by two peritoneal injections of 0·3 ml. complete Freund adjuvant emulsified in saline a fortnight apart. After about 3 weeks, when the animals had abundant ascitic fluid, immunization was carried out by injecting subcutaneously 500 μg of highly conjugated dinitrophenylated (DNP) ovalbumin mixed with $Al(OH)_3$ gel[7-9], followed 2 to 3 weeks after by two weekly injections of DNP ovalbumin emulsified in complete Freund adjuvant. Ascitic fluid was collected several times from the mice after these treatments. The pooled ascitic fluid contained about 1 mg/ml. of total precipitating anti-DNP antibody. Specific purification of anti-DNP antibody was made in the cold, following essentially the method of Farah *et al.*[13], with minor modifications[14]. The antigen used for precipitation was DNP bovine serum albumin (DNP-BSA) and the monovalent hapten was DNP-OH. From 77 mg of antibody in the ascitic fluid, 34 mg (44 per cent) of purified antibody was recovered. The concentrations were calculated measuring the optical density at 2800 Å, assuming that o.d. per μg of protein is 0·00143. Immunoelectrophoretic analysis indicated the presence of γ_1 and γ_2 (ref. 5).

Anaphylactic activity of the purified antibody could be demonstrated by passive cutaneous anaphylaxis (PCA). When 10 μl. of serial dilutions of purified antibody was injected into the skin or ear of several recipients[9,15], positive PCA reactions were obtained at concentrations of 2·5 μg/ml. or 80 μg/ml., when challenge was made after 2 h on 10 days respectively. The PCA reaction after 10 days was negative if the antibody was previously heated at 56° C. These results indicated that both γ_1 and the reaginic antibodies were present in the preparation.

In vitro experiments were performed as described[7-10] with peritoneal cells obtained from normal Swiss mice, about 2 months old. The cells were washed three times in Barron-modified[16] Ringer solution, by centrifugation, and finally resuspended so that a concentration of 200,000 to 400,000 mast cells were present per ml. Sensitization with purified antibody was carried out at various temperatures and for different times, as indicated. The total volume of the antibody-cell mixtures was about 0·4 ml. The antibody preparations were dialysed against Ringer solution before they were added to the cells. After sensitization the cells were washed five times with 1 ml. Ringer medium, resuspended in 0·2 to 0·4 ml. of the same medium and incubated at 37° C for 15 min. 1 μg of specific antigen (DNP-BSA) in a volume of 10 μl. was then added, and incubation at 37° C was continued for a further 5 or 10 min. The degranulated and intact mast cells were counted after staining with toluidine blue. Histamine release was measured by bioassay, after centrifugation, in both supernatants and the sedimented cells[9].

Table 1. *In vitro* SENSITIZATION OF MAST CELLS WITH REAGINIC ANTIBOD

Experiment	Conditions of sensitization: Antibody concentration (μg/ml.)	Time	Temperature (°C)	Per cent of degranulated cells
1	625	19 h	4	63
	312	19 h	4	29
2	625	17 h	4	70
3	625	17 h	4	34
	625	10 min	4	2
4	625	1 h	20	52
	625	30 s	20	4
	625 heated*	1 h	20	2

After sensitization, and before challenge with the specific antigen (1 μ DNP-BSA), the cells were washed five times.

* Antibody previously heated at 56° C for 5 h.

The results obtained in various conditions and in different experiments with cell suspensions from different animals are presented in Table 1. It can be seen that sensitization of the cells, as shown by mast cell degranulation, was readily achieved at a concentration of total antibody of 625 μg/ml., after incubation for 1 h at 20° C. or overnight at 4° C. At a concentration of 312 μg/ml. of antibody, sensitization was reduced. Sensitization for very short periods of time (10 min at 4° C, or immediate centrifugation after addition of the antibody at room temperature) was ineffective; in experiment 2 of Table 1 histamine release was also measured and amounted to 43 per cent of the total histamine of the cells. Heating of the antibody at 56° C for 5 h completely abolished the sensitizing capacity. Controls performed with cells to which no antibody or no antigen was added, but otherwise treated in the same manner as the other experiments, gave minimal degranulation or histamine release (2 to 5 per cent). No sensitization was obtained with whole serum containing reaginic antibody even at higher concentration.

Experiments were performed to verify the action of the γ_1 antibody contained in the purified preparation by incubating the mast cell suspension for 10 min at 37° C without further washing. In such experiments, degranulation of 50 per cent of the mast cells was obtained at a concentration of 2·5 μg/ml. of antibody, and challenge with 1 μg/ml. of DNP-BSA. Heating of the antibody at 56° C for 5 h did not affect the sensitizing activity caused by the γ_1 antibody.

The results in Table 1 cannot be attributed to an incomplete washing of γ_1, but really result from the firm fixation of reaginic antibody on the cells. In effect, negative results were obtained when the times of incubation with antibody, before washing, were too short, or when the antibody was previously heated at 56° C.

The fact that sensitization was obtained *in vitro* only with purified antibody, and not with whole antiserum, suggests that non-specific γ-globulin of the reaginic class interferes by competition for a receptor site on the cells with the reaginic antibody. In contrast, the fact that the preparation of antibody contained a great amount of γ_1 antibody in relation to reaginic antibody, suggests that γ_1 does not interfere with the sensitization of the cell by reaginic antibody.

Diffusion factors are minimized in our *in vitro* system, and this could be a valuable tool for acquiring more knowledge about the cellular mechanisms of sensitization. Further experiments are in progress.

Presence of HL.A Antigens on Human Reticulocytes as demonstrated by Electron Microscopy

THE presence of human histocompatibility antigens (HL.A) has been demonstrated on all the human nucleated cells so far studied, but unlike mouse H2 antigens they have not been found on erythrocytes. Harris *et al.*[1], using serological methods, have suggested that they might be present on human reticulocytes. By electron microscopy and an indirect Ferritin labelled antibody technique[2], we have studied these antigens at the membrane of bone marrow erythroblasts and erythrocytes. We have observed them on erythroblasts and reticulocytes and their disappearance on mature erythrocytes. Heparinized bone marrow was obtained by sternal aspiration from three subjects, two normal (A Rh^+ and O Rh^+) and one with mild aplastic anaemia (A Rh^+). The supernatant rich in leucocytes was collected after partial sedimentation of erythrocytes. Cells were washed three times in phosphate buffered saline *p*H 7·2 (PBS) containing 20 per cent foetal calf serum. Aliquots of 5×10^6 cells were incubated for 30 min at 37° C in a 1/3 dilution of an anti-HL.A antiserum, washed three times in PBS, and incubated for a further 30 min at 37° C in ferritin labelled sheep globulin antihuman IgG, prepared as previously described[3]. After three more washings, cells were fixed with glutaraldehyde postfixed in osmium, dehydrated in alcohol and embedded in Epon. Sections were stained with uranyl acetate and lead acetate[4] and examined using a Siemens E IA electron microscope with a magnification of 8,000 to 40,000 times. The anti-HL.A antiserum (provided by Professor J. Dausset) was a highly potent polyspecific anti-HL.A antiserum from a polytransfused patient. It reacted with the lymphocytes of 98 per cent of the French donors in cytotoxic tests up to a dilution of 1/500 to 1/1,000. The donor's blood, being group A, contained natural anti-B antibodies and no other detectable anti-erythrocyte agglutinins. In this respect it was tested against 12 isogroup donors using the immunoferritin technique and never reacted with erythrocytes.

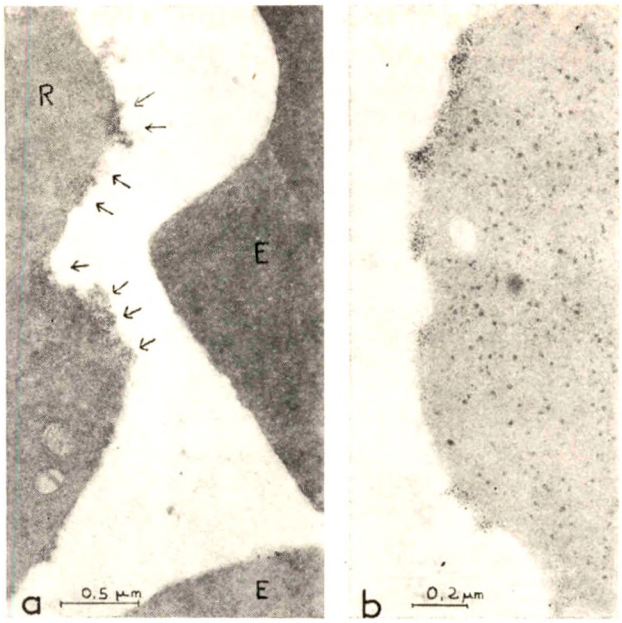

Fig. 1. *a*, Ferritin labelled reticulocyte (R) and unlabelled erythrocyte (E). ×35,000. *b*, Young reticulocyte with numerous "patches" of ferritin labelled areas. ×60,000.

We have already shown that HL.A antigenic sites are labelled as "patches" on the membrane of human lymphocytes[3]. These patches are 0·1 to 2 µm in length and separated by intervals devoid of any ferritin granules. The labelling observed on erythroblasts in the present experiments was similar, but the patches were less numerous and smaller than on the lymphocytes from the same subject. Bone marrow erythroblasts reacted whatever the stage of maturation, but labelling of the membrane was somewhat larger on the late erythroblasts than on the more immature cells. Specific HL.A labelling was never found on the membranes of mature erythrocytes with any of the anti-HL.A antiserum or cell donors. In the same experimental conditions, anti-blood group A or B antisera strongly labelled the erythrocytes bearing the corresponding antigens (D. S., F. M. K., M. G. N., J. P. L. and A. Senik, manuscript in preparation). The most striking observation is that all the examined reticulocytes, easily identified by the presence of polyribosomes and/or mitochondria, were found to be labelled with anti-HL.A antiserum (Fig. 1). No labelling was observed with ferritin conjugate when the cells were preincubated in normal serum from AB blood group donor, or in sera devoid of anti-HL.A antibodies.

These observations demonstrate that HL.A antigens are present on reticulocytes although they are not found on mature erythrocytes. Their disappearance from the latter is considered to be a pre-terminal event in the maturation of erythrocytes, which happens very late in the life of the reticulocyte, since no reticulocytes lacking HL.A antigens have yet been found in our preparations.

The disappearance of HL.A antigens from red blood cell surfaces might be due to the "masking" of these antigens at the membrane of mature erythrocytes. In fact, this is improbable because the immunization of human volunteers with erythrocytes failed to induce an anti-HL.A immune reaction detectable serologically or by skin grafting[5]. It is possible that HL.A antigens are eliminated from the cell membrane when important structural modifications of the membrane occur at the terminal stage of erythrocyte maturation, but it is more probable that the HL.A antigens at the cell surface are constantly renewed, as has been suggested for other macromolecules and

antigens[6,7]. The synthesis of HL.A antigens would persist in reticulocytes in which a high level of haemoglobin synthesis occurs. The duration of synthesis of the HL.A antigens would depend on the survival time of their messenger RNA and it would stop at the end of erythrocyte maturation with the disappearance of the polysomes and mitochondria. In this hypothesis HL.A antigens, in contrast with erythrocyte antigens, would be very short lived and quickly eluted or destroyed, disappearing very rapidly as soon as their synthesis stops. It is important to mention that the disappearance of HL.A antigens from the cell surface coincide with drastic changes in the morphological aspect and the general properties of red cell membrane. The relationships between changes in the structure and the antigenicity of the red cell membrane may suggest a model for the study of the role of HL.A antigens in cell membrane structure.

Failure of Long-established Skin Homografts on ALS-treated Mice to induce Transplantation Tolerance

The ultimate immunological status achieved by treating animals with antilymphocyte serum (ALS) superficially resembles immunological tolerance. The induction of tolerance has been refuted as a likely mode of action of ALS[1], except in conjunction with thymectomy[2,3], but ALS can—like other immunosuppressive agents[4-8]—promote the induction of transplantation tolerance[9]. While testing five ALS preparations for their activity to prolong skin homograft survival, we noted that these antisera were quite potent, facilitating the prolonged survival of a large percentage of test skin homografts. We therefore wondered whether or not the presence of homologous skin on ALS-treated mice for a long time would induce tolerance to the transplantation antigens present in the test graft.

ALS was raised in 2–4 month old New Zealand white rabbits by injecting 200×10^6 CBA mouse lymph node cells (suspended in 0·5 ml. of physiological saline and mixed with 0·5 ml. of Freund's complete adjuvant) in all footpads. This was repeated 3 weeks later and the rabbits received a third dose of 100×10^6 CBA node cells in saline intravenously 1 week later. Rabbits were exsanguinated 1 week after the third injection. The sera were heat-inactivated (56° C for 30 min) and sterilized by filtration. CBA mice were used to test the activity of the ALS preparations. Mice received 0·5 ml. of serum subcutaneously 2 and 5 days after transplantation with full-thickness A skin grafted orthotopically on the right chest according to a standard method[10]. ALS-treated mice that bore healthy A skin tests grafts for 109 days (group I) or for 181 days (group II) were regrafted with full thickness skin from A mice and—for control purposes—with skin from C57Bl/6 mice on the left chest. ALS-treated mice that had rejected A test skin grafts some time before day 109 or 181, respectively, were similarly regrafted with A and C57Bl/6 skin, as was a group of normal CBA mice. To avoid bias, A and C57Bl/6 skin grafts were placed alternately in the upper and lower graft beds. Grafts were first inspected 9 days after the operation and then daily.

Table 1 summarizes the results. CBA mice of group I originally comprised thirty animals, used to test the potency of three ALS preparations. When regrafted 109 days after the primary A skin grafting, twenty-eight animals were available. The activities of two other preparations of ALS were tested using twenty CBA mice. Of these thirteen and fourteen could be regrafted satisfactorily in group II 181 days after primary A skin grafting. Although there was considerable variability in the survival times of both A and C57Bl/6 skin grafts, particularly in group II, mice bearing long-established A skin grafts clearly did not support the prolonged survival of a second A graft. The rejection of such grafts seemed to follow first-set kinetics irrespective of whether the original A test graft was still retained or had been rejected. With respect to time, rejection was not different from that of skin of the unrelated strain C57Bl/6, nor from that of A and C57Bl/6 skin grafted to normal CBA mice (controls). Thus, neither tolerance nor sensitization had occurred.

During rejection of a second A skin graft and of the simultaneously grafted C57Bl/6 skin transplant, the primary A test grafts showed no signs of rejection. Hair clipped on the occasion of regrafting grew again normally and the grafts resumed their pregrafting appearance. In fact, on termination of the experiment, ten of the sixteen animals in group I which were regrafted 109 days after being forced to accept an A skin graft under ALS treatment still bore viable grafts 297 days later (406 days total). One CBA mouse of this group rejected its A test graft 99 days later (208 days total), whereas in five mice A grafts suffered chronic contracture and were considered rejected 85 days later (194 days total, two mice), 71 days later (180 days total, two mice), and 57 days later (166 days total, one mouse). Of the seven animals in group II, four bore healthy skin grafts 329 days after regrafting (510 days total), and one CBA mouse died with a viable graft 297 days afterwards (478 days total). In the remaining two mice of this group the A test grafts

Table 1. SURVIVAL OF A AND C57Bl/6 SKIN GRAFTS ON ALS-TREATED CBA MICE WHICH HAD RETAINED OR REJECTED A SKIN TEST GRAFTS

Table 2. FATE OF HAMSTER SKIN GRAFTS TRANSFERRED TO NORMAL OR HOMOGRAFT SENSITIZED HAMSTERS AFTER RESIDENCE FOR 150 DAYS ON F1 HYBRID HAMSTER HOSTS

Skin graft transferred from hybrid hamster host	No. of grafts	Immune status of new hamster host	Survival times of skin grafts (days)
LSH from (CB × LSH)F1	5	Normal LSH	5 × > 98
LSH from (CB × LSH)F1	15	LSH sensitized to CB	1 × > 143; 3 × > 98; 1 × 70; 2 × 20; 1 × 18; 1 × 16; 1 × 13; 5 × 7
CB from (CB × LSH)F1	6	CB sensitized to LSH	3 × > 143; 1 × 16; 2 × 10
MHA from (CB × MHA)F1	5	MHA sensitized to CB	3 × > 209; 2 × 96

underwent chronic contracture and were regarded as lost 122 and 52 days later (303 and 233 days total).

These results strongly suggest that A skin homografts accepted by CBA mice under the influence of ALS do not constitute a strong enough stimulus to confer transplantation tolerance, in spite of the fact that CBA hosts supposedly were exposed to A transplantation antigens for up to 181 days. The observation that rejection of a second A skin graft did not harm long-established A test grafts on the same animal requires an explanation. The only evidence of the A antigenicity of these original A test grafts was their crop of albino hair; there is no evidence as to whether or not the vascular endothelium of these grafts was of A or of CBA antigenicity.

An obvious procedure to test the antigenicity of these original A test grafts would be to transplant them back on normal A strain mice and to observe acceptance or rejection. This was not attempted, however, for two reasons: first, because the skin grafts persisting on ALS-treated mice seemed too small to allow satisfactory transplantation; the second, because earlier experiments with Syrian hamsters on a similar problem had yielded equivocal results. In these experiments, large skin grafts (about 2 × 2 cm) from parental strain hamsters were excised from appropriate female F1 hybrid recipients (Table 2) after 150 days. The edges of these grafts were trimmed by several millimetres to ensure the removal of any ingrown skin of host origin, and the grafts were transplanted either to normal parental strain male hamsters or to similar hamsters sensitized by skin homograft rejection to the antigens which might have been "picked up" by the grafts during their 150 days on appropriate F1 hybrid hosts. The fate of these grafts on their new hosts is shown in Table 2. The results with normal secondary hosts were clear-cut: replacement of vascular endothelial and fibroblast cells was not evident. When, on the other hand, sensitized secondary hosts were used, the results were less certain. Of twenty-six grafts so tested, 50 per cent were rejected within 20 days, and 50 per cent survived for 70 days or longer. Although this would indicate that at least in half of the grafts replacement of the vascular endothelium by that of the host had taken place during prolonged residence, as suggested by Billingham *et al.*[11], the reliability of these results is questionable. Similar difficulties were experienced with these grafts by Silvers *et al.*[12], that is, healing-in crisis of the rather thick and fibrotic grafts, and partial necrosis and contracture, which made transplantation and scoring somewhat hazardous. But it is difficult to ascribe all rejections to purely technical reasons. Clearly a more reliable means should be used to reveal the possessor of the vascular endothelium of long-accepted skin grafts. The use of fluorescent antibodies, as suggested by Medawar[13], should help to throw light on this most challenging problem of transplantation biology which has puzzled many investigators[14–18].

This work was supported in part by a grant from the Swiss National Foundation for Scientific Research. I thank Professor J. Lindenmann for advice and Mrs M. Heizmann and Miss R. Keller for assistance.

Differential Rejection of Neurones and Neuroglia in Canine Cardiac Allografts

USING a free-grafting technique, Barnes[1] demonstrated that brain tissue is at least as antigenic as skin allografts in mice. After the grafting procedure the neuronal cells become necrotic in his experiments, whereas the associated neuroglia, being more resistant to ischaemic anoxia, survived. A second-set form of rejection was found on subsequent skin grafting. He concluded that in this type of brain allograft, antigenicity is dependent on viable glial tissue. Such free-grafting experiments however, give no indication of the reactions invoked by viable neurones. An answer to this problem is important in the consideration of integrated neural allografting as in whole nerve, heart and brain grafts, for example.

As part of a study of the effects of immunosuppressive agents on the survival of canine cardiac allografts, we have noted the presence of histologically normal neurones in ganglia in proximity to both the sino-atrial and atrioventricular nodes in transplanted hearts. We used the technique of cervical cardiac allografting described by Mann *et al.*[2], which involves establishment of circulation through the coronary system of the implanted heart by anastomosis of the common carotid artery and external jugular vein of the recipient animal to the aortic arch and pulmonary artery, respectively, of the implant. Unmatched mongrel male dogs were used as donor and recipient animals. The average time of cardiac ischaemia was 20 min, during which period the heart was maintained at 5–10° C by immersion in saline. The mean survival time of implants without immunosuppressive therapy was 8 days, whereas survivals of up to 37 days were achieved by immunosuppression with azathioprine and hydrocortisone. The diagnosis of terminal rejection was based on progressive ventricular failure and on gross

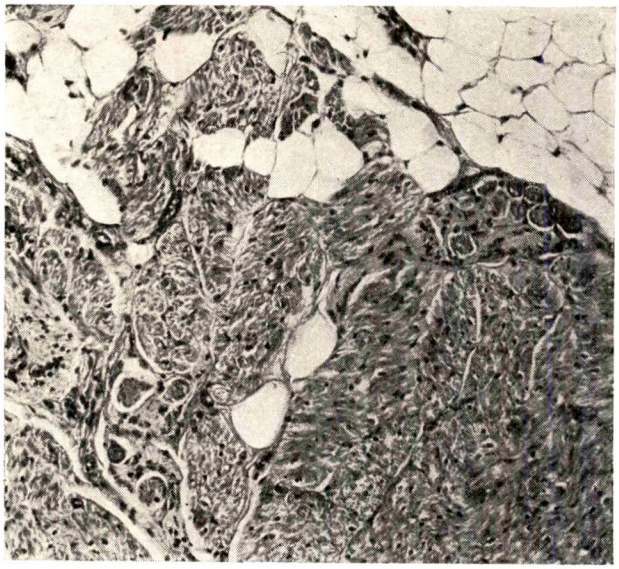

Fig. 1. Low power (×84) view of ganglia in recipient heart.

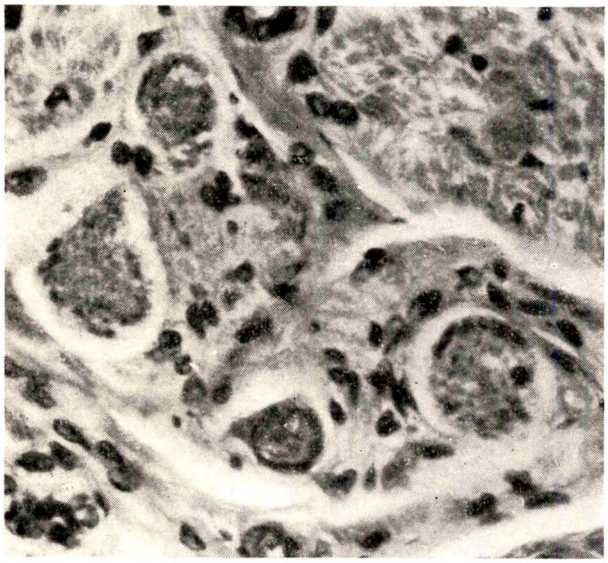

Fig. 2. High power (×330) view of ganglion in recipient heart.

electrocardiographic deterioration, but most hearts were still beating feebly when removed.

The implant was removed and the recipient animal killed, and appropriate blocks from both hearts were then fixed in 10 per cent buffered formalin. Routine 6 μm sections were stained with haematoxylin and eosin, periodic acid–Schiff, methyl-green pyronine and picro-Mallory stains. Sections from eight implant-recipient heart pairs, with an implant survival of at least 8 days, were examined. All implanted hearts demonstrated the typical features of cellular graft rejection[3], but sections from recipient hearts including the ganglia were essentially normal (Figs. 1 and 2). The cellular infiltrate, which consisted of lymphocytes, larger mononuclear cells and occasional neutrophils, was particularly conspicuous in and about neural ganglia, being much more intense than in the surrounding myocardium (Figs. 3 and 4). Nevertheless in all cases, the neurones were well preserved, whereas the supporting cells of the ganglia were destroyed. This condition of differential destruction prevailed not only in unmodified rejection but also in the ganglia of hearts which had survived for up to 37 days with immune suppression.

Our observations indicate that neural tissue in allo transplanted hearts is intimately involved in the rejectio process, so that as a whole it is at least as antigeni as cardiac muscle. The intensity of cellular infiltrat about the ganglia may imply that such tissue is mor strongly antigenic than cardiac muscle, but other factor such as the greater vascularity of the areas in whic these ganglia were situated must also be considered.

Of possibly greater significance is the observatio that neurones in the ganglia were spared, whereas th associated supporting tissue was not. The normal light microscopic appearance of neurones further suggest that they are only weakly antigenic and could be expecte to survive in the allografted heart. We have institute long term experiments to test this hypothesis and t elucidate the nature of the apparent host tolerance t neural cells.

Antitumour Effect of Lymphoid Cells activated by Interferon

INTERFERON induces a cytotoxic effect in normal mouse spleen cells against allogeneic tumour target cells in tissue culture[1,2]. We here present evidence that syngeneic lymphoid cells may be similarly activated by interferon and that syngeneic lymphoid cells plus interferon suppress the growth of tumour cells *in vivo*.

Interferon was prepared in L cells. Chick embryo allantoic fluid containing Newcastle disease virus (NDV) of initial activity 10^9 ID_{50}/ml. (320 haemagglutinating units per ml.) was irradiated with ultraviolet light until ineffectivity to chick embryo was completely lost. The fluid containing inactivated virus was diluted 1 : 20 in 'medium 199' and was then added to monolayer L cell culture. The culture medium was collected after incubation for 48–72 h and 6 M HCl was added to pH = 2. It was then kept at 4° C for 72 h and neutralized with 6 M NaOH to pH 7·5. To check the activity of the interferon the preparation was titrated on L cells. These preparations completely protected L cells from the > 100 $TCID_{50}$ (50 per cent tissue culture infectious doses) of encephalomyocarditis virus.

To check the toxicity of interferon against L cells each sample of interferon was titrated on L cells before use The dilutions used in the experiments were those which did not destroy L cells

The control culture fluid was prepared in the same way, irradiated allantoic fluid of normal embryos being added to L cells.

In the *in vitro* experiments, we used as target cells a line of mouse fibroblasts (L cells) which had been first obtained by Earle from tumour cells of mouse strain C3H (ref. 3). The seeded dose was 10^5 cells/ml. Each tube contained 1 ml. of the liquid. Spleens and lymph nodes from mouse strains BALB/c, C57Bl/6j, C3H, C3H(f)D and from F_1 hybrids between the first two strains were removed aseptically. These organs were disrupted to produce a cell suspension in medium 199. The suspensions were then filtered through two layers of gauze and washed three times with medium 199 by centrifuging at 600g for 10 min at 4° C.

The design of experiments *in vitro* has been described elsewhere[1,2]. Interferon and the control fluid were added to L cells together with lymphocytes. In all the experiments there were control tubes in which interferon and the control fluid were added to the L cells without any lymphocytes. The results of the experiments were obtained by counting the number of live L cells on the second or third day of incubation.

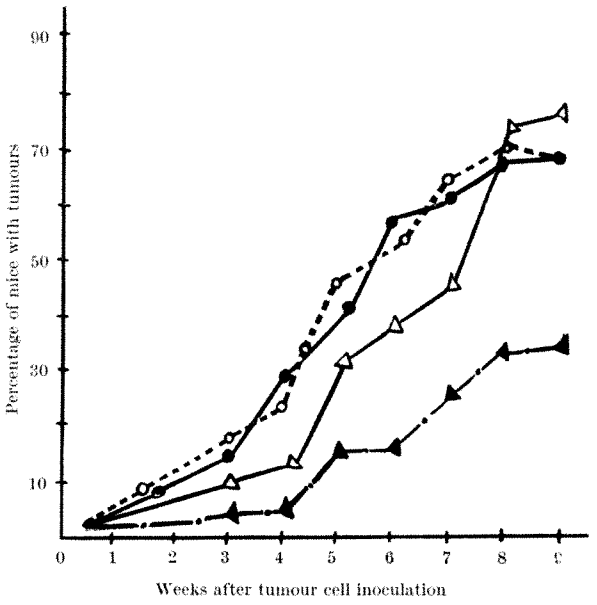

Fig. 1. Rate of tumour development. ○ - - - ○, Tumour cells (group 1); ●——●, tumour cells and lymphocytes (group 2); △——△, tumour cells and interferon (group 3); ▲——▲, tumour cells, lymphocytes and interferon (group 4).

Experiments *in vivo* were carried out with mouse strain C57Bl/6j (20–30 g). Tumour cells were obtained from syngeneic C57Bl/6j mice, with primary sarcomas induced by intramuscular inoculation of 9,10-dimethyl-α-benzanthracene in oil. Cell suspensions were prepared from tumours which were aseptically removed and then minced and filtered through two layers of gauze. The suspensions were washed by being centrifuged twice in Hanks's solution. The viability of tumour cells was checked by staining with eosin–trypan blue. Suspensions of spleen cells were prepared simultaneously with those of tumour cells as described for experiments *in vitro*. Tumour and spleen cell suspensions were mixed in appropriate ratios. Some of the mixed suspensions were diluted with medium 199, the others with interferon. The cell suspensions were maintained at freezing point. 1 ml. samples of the mixed suspensions (with or without interferon) were injected subcutaneously into mice without previous incubation.

The mice were organized into four groups, each group consisting of ten to fifteen mice. Controls were inoculated with tumour cells alone, tumour cells plus syngeneic lymphocytes or tumour cells plus interferon. The experimental group consisted of mice inoculated with tumour cells plus lymphocytes and interferon. Between 10^6–10^7 tumour cells were injected into each mouse and 50–100 times as many lymphocytes. Before tumours appeared mice were observed weekly; after tumours started growing, they were observed twice a week. The results *in vitro* were analysed by Student's t test, *in vivo* results by the χ^2 method.

As shown in Table 1 interferon alone caused inhibition of the growth of L cells in some experiments (Nos. 6–8). But in most experiments it did not inhibit the growth of cells and even stimulated it. Allogeneic spleen cells alone either failed to affect the growth of cells or destroyed them.

When interferon was added with allogeneic spleen and lymph node cells it always had a destructive effect on L cells. This effect cannot be interpreted as a result of the toxicity of interferon added to that of the lymphocytes: in all the experiments but one, neither a single component nor both of them used separately destroyed L cells, but when used together they exerted a marked cytotoxic effect. Syngeneic lymphocytes tested in the

* Spleens were used in experiments 1–6, 9–10; lymph nodes in experiments 7–8.
† In experiments 1–3, 10 and 5, 9, five different samples of our own preparation of interferon were used. Their activities, expressed in antilogarithms, show the differences in the titres of encephalomyocarditis virus (in $TCID_{50}$) in non-treated cultures and those treated with interferon. The activities of interferon in our samples were respectively: 100; 1,000; 10,000; 100 and 1,000. In experiment 4 we used Difco interferon (activity 500 units/ml.) kindly provided by Dr T. C. Merigan.

* 5×10^1–10^2 lymphocytes per tumour cell.

same series of experiments (Table 1) also caused destruction of L cells under the influence of interferon. Control fluid alone as a rule did not affect the growth of tumour cells. Neither did it induce a cytotoxic effect of lymphocytes. The difference between the number of live cells in the experimental group (lymphocytes plus interferon) and their number, even in that control group where it was the least, was always statistically significant: $P < 0{\cdot}05$.

Fig. 1 and Table 2 summarize the results of three experiments *in vivo*. Interferon alone did not affect either the rate or the incidence of tumour development. Neither did syngeneic lymphocytes when used alone. By contrast, interferon inoculated together with syngeneic lymphocytes reduced the number of tumours and delayed their development. The suppression of tumour growth was statistically significant.

The mechanism of the effect of interferon on lymphoid cells remains obscure but our results suggest that it activates lymphoid cells and makes them able to suppress the growth of tumour cells. Recently the suppression of tumour growth in animals inoculated with interferon inducers has been described[5,6]. Such suppression is probably related to the activation of lymphocytes by interferon. The suggestion is also supported by the finding that allotransplantation reaction is increased (personal communication of H. B. Levy) by the double-stranded polyribonucleotide poly I·poly C. It is of interest that in Levy's experiments, administration of double-stranded RNA suppressed the development of leukaemias to a much lower degree. This may be attributed to defective lymphocytes which failed to be activated by interferon.

Foetal Adrenal Necrosis induced by 7-Hydroxymethyl-12-Methylbenz(a)-anthracene and its Prevention

THE polycyclic hydrocarbon 7,12-dimethylbenz(a)-anthracene (DMBA), a potent carcinogen, has been used extensively to study the induction of mammary tumours in rats[1–3]. Among its other biological effects, DMBA produces severe necrosis of the inner zones of the adrenal cortex in the mature rat[4]. The immature rat (< 30 days of age), however, is not susceptible to the adrenocorticolytic effects unless it is pretreated with ACTH (ref. 5). In the mature rat 7-hydroxymethyl-12-methylbenz(a)-anthracene (7-OHM-12-MBA), a derivative of DMBA, has a more powerful adrenocorticolytic action than the parent hydrocarbon[6], but it also has no effect on the adrenal gland of the immature rat[7]. Pretreatment with β-diethylaminoethyldiphenyl-*n*-propyl acetate (SKF 525-A), a potent inhibitor of hepatic microsomal drug-metabolizing enzymes, protects the adrenal glands of the mature rat from the damaging effects of both DMBA and 7-OHM-12-MBA (ref. 8).

Recently we described the embryopathic actions of DMBA and 7-OHM-12-MBA in the Sprague-Dawley rat[9]. We now report that at day 17 of pregnancy the adrenal glands of the rat foetus are susceptible to the adrenocorticolytic effects of 7-OHM-12-MBA and, further, that these can be prevented by pretreatment with SKF 525-A.

Pregnancy was timed and confirmed as described before[9]. The foetal adrenal glands were obtained from the litters of Sprague-Dawley rats treated on day 17 of pregnancy with a single intravenous dose of 7-OHM-12-MBA (2·5 mg/100 g maternal body weight) in an oil emulsion. Controls received an equivalent volume of oil emulsion which contained no hydrocarbon. The mothers were killed on day 20 of pregnancy; their adrenal glands and at least five pairs of foetal adrenal glands from each litter were fixed in 4 per cent neutral buffered formaldehyde. Paraffin sections were stained with haematoxylin and eosin.

In all cases following treatment with 7-OHM-12-MBA on day 17 of pregnancy, the foetal adrenal glands were

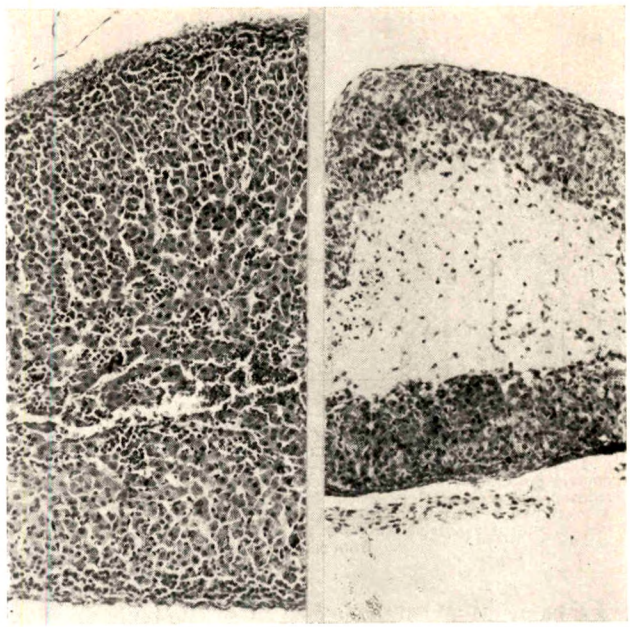
—	Control emulsion	2 (15)	0/15
SKF 525-A	7-OHM-12-MBA	4 (21)	0/21*
Saline	7-OHM-12-MBA	3 (20)	20/20
SKF 525-A	—	3 (25)	0/25

* Eight pairs showed histological evidence of scattered single cell necrosis in e central zone.



duced in size and they all showed severe necrosis of he central zones (Table 1). The severity varied a little a degree not only between litters but also within the ame litter: in most glands the necrosis was diffuse Fig. 1), but in a few, though severe, it was focal in charac-er. The necrosis involved the inner part of the cortex nd the presumptive medullary zone, which in the 20 day oetus is composed of irregular cords of adrenocortical ells surrounding the clusters of sympathetic medullary-ell precursors; the outer part of the zona fasciculata ontained single scattered necrotic cells, but the zona lomerulosa was undamaged. None of the adrenal glands rom the control groups treated with the oil emulsion howed any evidence of necrosis. The adrenal glands of he mothers all showed extensive severe cortical necrosis.

The results of pretreating with SKF 525-A before hallenge with 7-OHM-12-MBA at day 17 of pregnancy re shown in Table 1. SKF 525-A, dissolved in saline, vas given intraperitoneally (2 mg/100 g maternal body veight) 30 min before 7-OHM-12-MBA. Control animals eceived an intraperitoneal injection of an equivalent olume of saline or SKF 525-A. The mothers were killed n day 20 of pregnancy. Pretreatment with SKF 525-A effectively protected the adrenal glands of the foetuses nd severe necrosis was not found in any case. In approxi-mately 40 per cent of the "protected" glands, however, here was histological evidence of slight damage in the central zones—nuclear pyknosis or necrosis of scattered single adrenocortical cells. The adrenal glands of the mothers were fully protected by SKF 525-A pretreatment.

It is interesting that the adrenal glands of the 17 day foetal rat should be susceptible to 7-OHM-12-MBA whereas those of the postnatal immature animal are not. Because a metabolite of 7-OHM-12-MBA is probably the ultimate adrenocorticolytic agent in the mature rat[10], and because the liver of the immature rat differs significantly in its microsomal hydroxylating activities from that of the mature animal[11], it seems likely that the foetal adrenal necrosis is due to the transplacental passage of an active adrenocorticolytic metabolite from the mother. This view is supported by the fact that SKF 525-A protects both the foetal and the maternal adrenal glands from 7-OHM-12-MBA.

It may also be significant that the foetal adrenal gland undergoes rapid growth and development from day 16 of pregnancy until birth under the influence of foetal ACTH (ref. 10), while adrenocortical functions diminish for a time in the early postnatal period[13]. The failure to induce adrenal necrosis with DMBA in the immature rat has been correlated with a diminution in the corticosterone content of the gland as compared with the mature animal: pretreatment with ACTH converts the refractory gland to a susceptible state[5], and it may be that active corticosterone biosynthesis is necessary for the adrenocorticolytic action of both DMBA and 7-OHM-12-MBA. If this is indeed the case it would seem from our experiments that the outer part of the zona fasciculata in the 17 day foetus differs functionally from the inner part of the cortex.

This investigation was supported by a grant to A. R. C. from the Scottish Hospital Endowments Research Trust. We thank Dr P. Sims, Chester Beatty Research Institute, Royal Cancer Hospital, London, for the 7-OHM-12-MBA and Mrs Marget Inglis, Miss Barbara C. Cruden and Mr G. Milne for technical assistance.

Influence of Hydrocortisone and Glucagon on Liver Tyrosine Transaminase and on Brain Tyrosine, Norepinephrine and Serotonin

CURRENT hypotheses concerning biochemical origins of endogenous depression centre around serotonin (5HT)[1] and norepinephrine[2–4] changes in the brain. Recently, attempts have been made to relate disturbances in biogenic amine metabolism in the brain to metabolic factors outside the brain. Green and Curzon found[5] that administration of hydrocortisone resulted in a decrease of 5HT in the brain (by way of an increase in tryptophan pyrro-

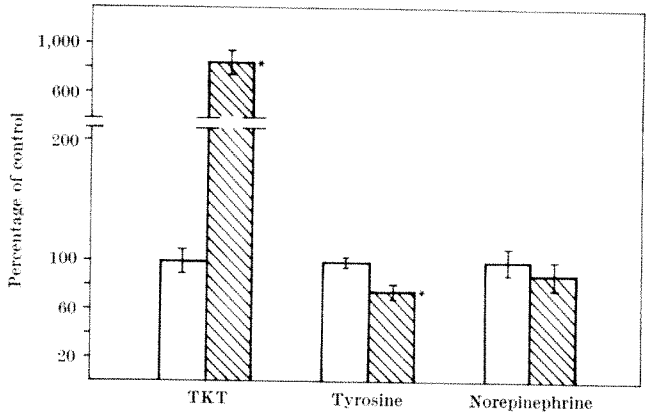

Fig. 1. Influence of glucagon and hydrocortisone on TKT in liver, tyrosine in plasma and norepinephrine in the whole brain. Enzyme activity of TKT was measured in percentage of control. The mean values for the control animals (100 per cent) are: tyrosine 10·8 μg/ml.; norepinephrine, 0·49 μg/g. Each group consisted of nineteen to twenty-two rats. Vertical bars indicate standard deviation of the mean. White columns, control animals; hatched columns, treated animals. * $P < 0.01$ differs from control.

lase, the principal catabolic enzyme of tryptophan). This evidence gives strong support to the 5HT hypothesis of endogenous depression[5,6]. Takahashi *et al.* noted[7] that after oral application of a tyrosine load there is a significant increase in the level of plasma tyrosine in maniacs and depressives as compared with control persons[7]. This increase is attributed to a reduced activity of α-ketoglutarate transaminase (TKT) (TKT is the principal catabolic enzyme of tyrosine) in patients with endogenous depression. Finally, patients with endogenous depression show a lower level of plasma tyrosine, phenylalanine, and tryptophan than normal subjects[8]. The reduction in the level of these amino-acids presumably leads to a disturbance in amine levels in the brain.

The influence of peripheral factors on amine metabolism in the brain is largely unknown. The possibility that one of the principal enzymes in tyrosine metabolism, TKT, has an influence on tyrosine levels and amine metabolism in the brain has not been investigated, but a recent study of brain TKT did suggest that this enzyme is important[9].

Chirogos *et al.*[10] have examined the possibility that high levels of plasma tyrosine influence tyrosine levels in the brain after the i.p. injection of tyrosine, and have shown that, after 1 h, the tyrosine levels in the plasma and brain were equal. We have attempted to establish whether a low level of plasma tyrosine is accompanied by a low level of brain tyrosine and, if so, if it affects the level of norepinephrine in the brain. TKT activity can be increased by hydrocortisone[11] and by glucagon[12,13], and it is also influenced by norepinephrine. High levels of norepinephrine suppress the TKT rhythm[14] and low levels of norepinephrine increase TKT activity in the liver[15], while lowering it in the brain[9]. Because hydrocortisone, by itself or together with glucagon, increases the level of tryptophane pyrrolase[12], which according to Green and Curzon[5] should lead to a reduction in 5HT levels in the brain, we attempted a replication of their findings.

The TKT activity in the livers of male Sprague–Dawley rats (200–300 g) was estimated according to Diamondstone[16]. Plasma and brain tyrosine were measured by the method of Waalkes and Udenfriend[17], and norepinephrine and 5HT in the whole brain were estimated according to Maickel *et al.*[18]. The animals were kept in normal lighting. Hydrocortisonacetate (2·5 mg/100 g i.p. 5 h before decapitation) and glucagon (0·5 mg/100 g i.p. 5 and 3 h before decapitation) were injected between 10.00 a.m. and 11.00 a.m. The rats were starved for the last 8 h before decapitation although tap water was freely available. The control animals received equal volumes of 0·9 per cent salt solution injected at the same times.

TKT was increased by glucagon and hydrocortisone approximately 835 per cent (see Fig. 1) in comparison with the control animals (100 per cent). The corresponding plasma tyrosine level was reduced by 24·5 per cent as compared with that of the control animals.

The reduced levels of plasma tyrosine can be attributed to the increased TKT activity[9,19,20]. The significant decrease in the levels of brain tyrosine is accompanied by a proportional decrease in plasma tyrosine (Table 1). Levitt *et al.*[21] have shown the effect of varying the tyrosine concentration in the perfusion fluid on the rate of norepinephrine formation in the heart. Because our lowered tyrosine levels are in the border area of full saturation of the tyrosine hydroxylase it was possible that there was reduced formation of norepinephrine.

Table 1. TYROSINE IN THE PLASMA AND BRAIN OF RAT

	Plasma	Brain
Control	10·6 ± 0·42	15·5 ± 0·64
Treated with hydrocortisone	8·3 ± 0·32*	10·9 ± 0·91*

Each group consisted of twelve rats. Results are expressed as μg/ml and/or μg/g ± s.d. of the mean. After injection of hydrocortisone + glucagon (five rats) comparable results were found. * $P < 0.01$ differs from control.

Our experimental animals showed a slight decrease (11·4 per cent) in the level of norepinephrine in comparison with the controls, but the difference is not significant (see Fig. 1), and there was no difference when the TKT was induced by about 550 per cent by giving hydrocortisone and glucagon independently. Moreover, in the heart, the increased TKT caused by glucagon and hydrocortisone (twenty-two rats) had no influence on the norepinephrine. After injections of glucagon and hydrocortisone, the TKT rises sharply so it can be assumed that normal daily changes in TKT level have no influence on norepinephrine levels in the brain.

The tryptophan pyrrolase level should also be increased by hydrocortisone and glucagon[12], but we found only a slight (5 per cent) and insignificant decrease in 5HT in the brains of our experimental animals (fifteen rats) compared with that in the control animals. With hydrocortisone alone, we also did not find any decrease in 5HT: one group of animals (ten rats) received a dose of hydrocortisone identical to that given by Green and Curzon (0·5 mg/100 g i.p.). As in Green and Curzon's study these animals were killed 6 h after injection. Another group (fifteen rats) received a dose five times as high (2·5 mg/100 g i.p., 5 h before decapitation), but again we did not find a decrease in the 5HT level in response to hydrocortisone (acetate) injections.

Our results show that a decrease in level of peripheral plasma tyrosine through an increase of TKT is accompanied by a parallel lowering of tyrosine level in the brain. The lowering of tyrosine levels in the brain does not result in a decrease of brain norepinephrine. Furthermore, we were unable to demonstrate a decrease of 5HT in the brain after application of hydrocortisone.

To summarize, we were not able to affect the levels of norepinephrine and 5HT in the brain by increasing the concentration of TKT and tryptophan pyrrolase in the liver. It is therefore unlikely that the decrease in the levels of biogenic amine in the brain, which is assumed to occur in endogenous depression, can be attributed to increased TKT or tryptophane pyrrolase production by the liver.

We thank Miss H. Gluba and Miss A. Renz for technical assistance, and the Lilly GmbH for providing the glucagon.

Synergistic Action of Sodium and Angiotensin on Brain Mechanisms controlling Water and Salt Balance

INFUSIONS of hypertonic NaCl into the third brain ventricle of goats have been found to cause drinking[1], release of antidiuretic hormone (ADH)[2] and natriuresis[3]. Thirst may also be elicited in the rat by intravenous infusions[4] and intrahypothalamic injections[5] of angiotensin. The effects of angiotensin and hypertonic saline on drinking are additive when both substances are administered intravenously to nephrectomized rats[4]. For these reasons it seemed of interest to study how infusions into the third ventricle of angiotensin alone, or in combination with moderately hypertonic NaCl, would affect central mechanisms of importance in the regulation of water and salt metabolism.

Slow (10 μl./min) infusions into the cerebrospinal fluid of the third ventricle were made for 30 min periods in five goats, and for repeated 5 min periods in two of these animals. The infusion technique has been described earlier[1]. The goats were either in normal water balance or were hydrated by giving 100 ml. of water/kg body weight by stomach tube into the rumen 90 min before the infusions were started. Angiotensin (Hypertensin, Ciba) was dissolved either in slightly hypotonic (0·12 M) NaCl, or in hypertonic (0·33 M) NaCl, and was infused at a rate of 1–2 ng/kg/min. For comparison infusions of 0·33 M NaCl without angiotensin were also made.

When the goats were in normal water balance, 30 min infusions of 0·33 M NaCl or of angiotensin dissolved in hypotonic saline caused cumulative drinking of a total of 1–2 l. of water. These infusions also resulted in a two to five-fold increase in renal sodium excretion. The infusions of angiotensin together with hypertonic NaCl induced much more conspicuous polydipsia and more pronounced natriuresis. The animals drank 4 to 6 l. of water and renal Na^+ excretion rose to levels about 1 mequiv/min (= ten times control excretion).

During hydration, 30 min infusions of 0·33 M NaCl or of angiotensin dissolved in hypotonic saline caused little or no drinking. A moderate inhibition of the water diuresis became apparent towards the end of the infusion period and lasted for about 40 min. Renal sodium excretion became moderately elevated (two to three times control level). Also in the hydrated goat, however, the combination of angiotensin and hypertonic NaCl acted as a powerful thirst stimulus, and water had to be withheld in order to prevent fatal overhydration. Conspicuous natriuresis developed during the 30 min infusions (peak level >ten times above control Na^+ excretion). The natriuresis was succeeded by a long-lasting (2 h), profound inhibition of the water diuresis with high urine osmolality.

In two of the goats 5 min intraventricular infusions of 0·33 M NaCl, of angiotensin dissolved in hypotonic saline, and of angiotensin together with 0·33 M NaCl were made alternately during hydration. The brief infusions of 0·33 M NaCl and of angiotensin dissolved in hypotonic saline did not inhibit the water diuresis of the animals. Five minute infusions of angiotensin dissolved in 0·33 M NaCl, however, effectively inhibited the water diuresis for 40 to 60 min. During this antidiuresis urine osmolality rose four to five times, implying that the inhibition was due to release of ADH.

The observation that injections of minute amounts of hypertonic NaCl into the anterior hypothalamus may elicit polydipsia[6] has led to the suggestion that a hypothalamic "osmoreceptor" mechanism in Verney's[7] sense regulates not only the release of ADH but also the urge to drink. Infusions of hypertonic glucose or saccharose into the third ventricle, however, apparently do not elicit thirst or release ADH in the goat[1,8]. This indicates that an elevated Na^+ concentration is a more efficient stimulus to the thirst eliciting and ADH releasing mechanisms than is a rise in extracellular osmotic pressure as such. The present study shows that all the effects on water and salt metabolism that are obtained in the goat by infusions of hypertonic NaCl into the third ventricle may be reproduced to a certain extent by similar infusions of angiotensin. It is also obvious that angiotensin markedly potentiates the effects of hypertonic NaCl infused into the ventricle. A possible explanation might be that angiotensin mimics the effect of an elevated extracellular Na^+ concentration by changing (increasing ?) the transport of Na^+ into brain cells which are involved in the regulation of water and salt metabolism. This would mean that the intracellular, rather than the extracellular, Na^+ concentration may determine the activity of these neurones.

Antagonism of Pressure and Anaesthesia

THE increase in ion permeability of 4 per cent phosphatidic acid–96 per cent phosphatidyl choline liposomes when exposed to liquid anaesthetics has been reported[1,2], and it was deduced that this increase was caused by increased freedom of movement of the lipid molecules, especially at the aqueous-lipid interface.

In 1950, Johnson and Flagler[3] reported that the spontaneous swimming motion of tadpoles disappeared when

they were anaesthetized with various liquid anaesthetics or when unanaesthetized tadpoles were exposed to hydrostatic pressures of 200–350 atmospheres. When anaesthetized tadpoles were exposed to hydrostatic pressures of 150–350 atmospheres, however, spontaneous swimming motions reappeared.

One possible hypothesis consistent with these facts is that in the anaesthetized state some membrane in the central nervous system of the tadpole is in an expanded state corresponding to the increased freedom of molecular motion in liposomes treated with anaesthetic. One would then expect the application of pressure to compress the membrane back towards the unanaesthetized, unexpanded state. At the same time the concentration or activity of the anaesthetic within the membrane should remain approximately constant, the changes observed being attributed to molecular "packing" effects.

To test this hypothesis we have exposed both newts and liposomes to anaesthetics and pressure. In liposomes we find that the increase in permeability to K^+ and Rb^+ brought about by the anaesthetics butanol, ether and nitrogen in doses just sufficient to abolish the righting reflex of newts can be counterbalanced by an increase in pressure of about 150 atmospheres. If higher doses of anaesthetic are used then higher pressures are required to restore the permeability to the unanaesthetized, atmospheric pressure level. Pressure was applied with the non-anaesthetic gas helium. Application of helium pressure alone led to a fall in ion permeability.

Similarly we have studied the ability of a newt (*Triturus eristatus*) to right itself[4] under the influence of anaesthetics and pressure. Butanol, ether and nitrogen at the doses used on liposomes abolished the righting reflexes. Application of pressure either hydrostatically or with helium restored the righting reflex at around 150 atmospheres. Application of pressure alone led to progressive loss of the righting reflexes above 150 atmospheres.

Both sets of experiments are broadly consistent with our hypothesis, and the remarkable parallelism between the newt and the liposome suggests a mechanism that is consistent in each case with the Meyer–Overton hypothesis which correlates anaesthetic potency with lipid solubility.

The evidence obtained by studying the nuclear magnetic resonance of anaesthetics (for example, benzyl alcohol) on erythrocyte, synaptosome, myelin and vagus nerve membranes[5,6] shows that the anaesthetic causes some increase in freedom of movement of all these membranes, and it is possible that the primary mechanism of action of the anaesthetic in all cases is an increase in the volume of the lipid part of the membrane, equivalent to an increase in disorder or freedom of movement of the lipid molecules. Such an effect might also cause conformational changes in proteins intimately associated with lipid.

Cell Potassium by ^{39}K Spin Echo Nuclea Magnetic Resonance

ALTHOUGH there is recent evidence[1–4] that cell potassiu is complexed, it is still generally believed that intercellul K^+ is in free solution. Nuclear magnetic resonan (NMR) has already provided direct evidence that anoth cellular cation (Na^+) is complexed[5–8,20,21]. When the sa approach was used to study cell ^{39}K, the first measuremen barely detected an NMR signal from saturated aqueo KCl with the same instrumentation which measured N at a concentration of 0·005 M. NMR sensitivity was limite primarily by the magnetic fields available from conve tional electromagnets (13,000 gauss). The key to succe sf NMR measurement of ^{39}K was the opportunity for t use, for a few days, of a superconductive magnet t generate a magnetic field of approximately 50,300 gaus Besides increased sensitivity resulting from a high resonant frequency, the superconductive magnet provide additional improvement in signal-to-noise ratio fro prolonged averaging made possible by the high stabilit of the magnetic field. A further improvement in exper mental technique was the use of pulsed NMR, whic meant that relaxation time could be measured directly thus eliminating some of the ambiguity inherent in th interpretation of steady state NMR data. A spin-ech NMR spectrometer (model PS60–AW, Nuclear Magneti Resonance Specialties, Inc.) operating at 10^7 Hz was used with a low noise preamplifier, and RC filtering of approx imately 50 per cent or less of T_2. Before each measure ment, the magnetic field was adjusted for NMR resonanc using the beat pattern of a saturated solution of K_2CO (12 M K^+). In spite of the improvements in instrumenta tion, the measurement of K^+ in a living system would stil not have been possible but for the use of a bacterium (*H. halobium*) with an extraordinarily high concentration o K^+ (4–5 M) (ref. 9 and unpublished results of M. and B Ginzburg).

At the NMR resonance of ^{39}K, a 1·0 M KCl solution subjected to a single 90° pulse showed a free induction decay (Fig. 1, lower), which conformed to a single exponential (Fig. 1, upper). Because the observed free induction decay is considerably shorter than would have been produced by the inhomogeneity of the field of our magnet

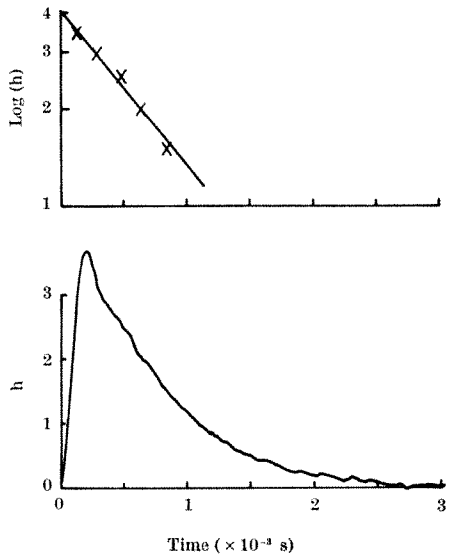

Fig. 1. Free induction decay of 1 N K^+. The lower curve shows free induction decay of 2 ml. of aqueous 1 N KCl solution at approximately 28° C. The voltage output of the sample (h) in arbitrary units is plotted against time after a single 90° pulse, which was repeated every 15×10^{-3} s. Data shown here are the mean of 400 repetitions of the experiment. RC filtering of $0{\cdot}52 \times 10^{-3}$ s was used. The upper curve is a semilog plot of the same data. Linearity indicates a single exponential decay, for which T_2 was estimated to be $0{\cdot}9 \times 10^{-3}$ s.

($1:10^5$ DSV), and because the shape of free induction decay produced by magnetic inhomogeneity should be Gaussian rather than simple exponential, we believe that the free induction decay in Fig. 1 is a measure of transverse NMR relaxation time (T_2). A similar interpretation has been used in other systems[12]. Three measurements of free induction decays of ^{39}K in aqueous 1·0 M KCl yielded a mean value of $0{\cdot}8 \times 10^{-3}$ s for T_2. As far as we know, this is the first published measurement of T_2 of ^{39}K in any state (liquid, solid, or biological). Only two steady state NMR studies of ^{39}K are known to us[10,11].

The concentration dependence of T_2 of aqueous ^{39}K was studied briefly. Mean values of T_2 for 1 M KCl, 4 M KCl, and 12 M K^+ (K_2CO_3) were 0·8, 0·9, and $1{\cdot}15 \times 10^{-3}$ s respectively. These data suggest that T_2 increases with increasing K^+ concentration, in contrast to Na^+, which behaves in the opposite way[14]. The difference may relate to the opposite effects of these two cations on the structuring of H_2O (ref. 15).

The NMR behaviour of K^+ in packed, wet ion exchange resin ('Dowex 50') is shown by the data in Table 1. T_2 observed for the K^+ signal in the wet resin is almost equal to that in aqueous solution. But the initial height of the free induction decay of K^+ in wet resin is only 41 per cent of the height expected for an aqueous solution of the same K^+ concentration as in the resin, indicating that 59 per cent of resin K^+ is invisible to this NMR technique (Table 1). It is reasonable to suppose that the invisible fraction represents K^+ complexed by the resin at charged sites with large electric field gradients, which interact with the quadrupole electric moment of ^{39}K to produce a T_2 which is significantly shorter than the instrumental filtering time constant of $0{\cdot}25 \times 10^{-3}$ s.

Table 1. NMR BEHAVIOUR OF K^+ IN PACKED WET ION EXCHANGE RESIN

	T_2	h_0
1·67 M K^+ on 'Dowex 50' resin (measured)	0·55	7·0
Aqueous 1·0 M KCl (measured)	0·60	10·1
Aqueous 1·67 M K^+ (calculated)		18·2

T_2 transverse NMR relaxation time in units of 10^{-3} s; h_0, initial height of the free induction decay, which was determined by extrapolation of the linear semilog plot back to $t=0$. The same arbitrary units of h_0 are used for both resin and control. Because h_0 should be directly proportional to concentration of K^+ (ref. 12), a 1·67 M KCl solution should have $h_0=18{\cdot}2$, which compares with $h_0=7{\cdot}0$ observed for the 1·67 M K^+ which was measured by flame photometry[13] in the ion exchange resin sample. The resin and the 1·0 M KCl both were 2 ml. in volume, and were measured in identical conditions, which include 2,048 repetitions averaged, RC filtering of $0{\cdot}25 \times 10^{-3}$ s, and a repetition rate of one experiment per 56×10^{-3} s. The cation exchange resin, 'Dowex 50-X4' (100–200 mesh), was converted to the potassium form by washing the resin on a Buchner funnel with 1 N KOH followed by 10 mM KPO_4 buffer (*p*H 8·0) and then packed by the same technique of centrifugation which was used for the bacteria. A sample (2 ml.) of this packed wet resin was used for NMR analysis.

Table 2. NMR BEHAVIOUR OF K^+ IN PACKED BACTERIA (*H. halobium*)

Sample	T_2 Data	Mean
Bacteria (sample 1)	0·37	0·37
Bacteria (sample 2)	0·40, 0·26	0·33
Aqueous 1·0 M KCl	1·25, 0·50	0·87

T_2 is transverse NMR relaxation time in units of 10^{-3} s. The bacterial samples and 1·0 M KCl were 2 ml. in volume, and were measured in identical conditions, which include RC filtering of $0{\cdot}3 \times 10^{-3}$ s, and a repetition rate of one experiment per 15×10^{-3} s. The number of measurements averaged varied from 1,250 to 4,000. The bacteria were grown approximately by the method of Kushner[19], and were packed into 2 ml. pellets by centrifugation at 100,000*g* for 30 min. K^+ concentrations of $2{\cdot}89 \pm 0{\cdot}13$ M and $3{\cdot}10 \pm 0{\cdot}10$ M per unit volume of packed bacteria were measured for samples 1 and 2 by techniques described before[13].

From K^+ in packed bacteria, we obtained a free induction decay, which was single exponential in shape (Fig. 2), from which T_2 was measured (Table 2). Because these values of T_2 for K^+ in bacteria (mean = $0{\cdot}35 \times 10^{-3}$ s) are almost as short as the RC filter time constant of the spectrometer ($0{\cdot}30 \times 10^{-3}$ s), it is possible that the real value of T_2 for K^+ in bacteria is considerably shorter than we recorded. The short T_2 of K^+ in bacteria compared with aqueous K^+ (Table 2) implies that electric field gradients near K^+ are higher in bacteria than in free aqueous solution, which suggests that cell K^+ is complexed by fixed charges[1–4,9], and/or is solvated in semicrystalline cell water (refs. 12, 16–18 and our unpublished results).

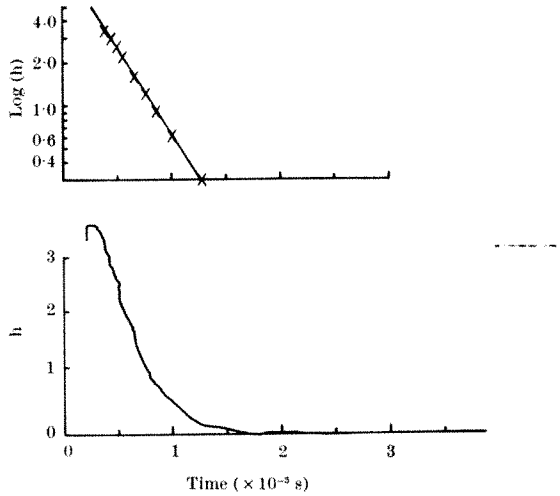

Fig. 2. Free induction decay of K^+ in bacteria. The lower curve shows free induction decay of K^+ in 2 ml. of packed bacteria (*H. halobium*) at 28°–33° C. The voltage output of the sample (h) in arbitrary units is plotted against time after a single 90° pulse. Data shown here are the average of 4,000 repetitions of the experiment at a rate of one repetition per 15×10^{-3} s. RC filtering of $0{\cdot}3 \times 10^{-3}$ s was used. The upper curve is a semilog plot of the same data. Linearity indicates a single exponential decay, for which T_2 was estimated to be $0{\cdot}37 \times 10^{-3}$ s.

We thank Nuclear Magnetic Resonance Specialties, Inc., for the loan of a superconducting magnet and liquid helium transfer equipment. We also thank the Sharples Centrifuge Company for the loan of its centrifuge for bacterial separations, Dr Stanley Schultz for laboratory facilities, the personnel of NMR Specialties for their assistance, Mr G. Donald Vickers for valuable suggestions and Mr Thomas G. Hill for his engineering skill. This work was supported in part by a grant from the Health Research Council of the City of New York.

Structural Implications of Banding in Unstained Collagen

THE three currently accepted three dimensional models for the structure of the collagen fibril predict alternating regions of high and low density along the length of the fibril, with a repeat length (D) of about 650 Å (Fig. 1*a*)[1–3]. As in the previous two dimensional "modified quarter-stagger" model[4,5], the denser regions (A bands) are about 0·4 D in length, the less dense or "hole" regions (B bands) are about 0·6 D, and the tropocollagen molecular length is 4·4 D. The electron micrographs of negatively stained native and reconstituted collagen, on which the models are largely based, vividly display large banded features which have been interpreted as due to the higher permeability of the B bands to the dense metal stain[6,7]. Although electron micrographs of unstained collagen fibrils could be expected to reflect the intrinsic longitudinal density distribution, very few studies have included such micrographs, and these were not detailed[8,9]. Consequently, we have re-examined unstained collagen fibrils by a simple technique. The observed density patterns seem to conflict with the above models and with the prevailing interpretation of negative staining in collagen.

Collagen fibrils were separated from the fresh Achilles tendons and tail collagen of 6 month old white rats by 10 kHz sound waves in distilled, deionized water. The supernatant was transferred to collodion-coated copper grids and dried. Negatively stained preparations were made with sodium phosphotungstate (Na-PTA) at *p*H 7·4 according to the technique of Cox *et al.*[10].

Micrographs were made on a modified RCA EMU 3-D electron microscope at 100 kV.

Fig. 1*b* shows an unstained tendon collagen fibril. Noteworthy are the wider dark bands with at least two asymmetrically located light lines in each, and the narrower light bands with two very light lines at their extremities. The widths of the dark and light bands are approximately 0·58 D and 0·42 D respectively; where D, the repeat length, is about 655 Å. For comparison, Fig. 1*c* shows a typical negatively stained fibril of rat tail collagen. The similarities in relative band lengths, relative densities and fine structure lead to the identification of the A and B bands in the unstained specimens exactly as in the negatively stained fibrils[6]. The same unstained banding pattern has been observed in beef tendon fibrils after demineralization by acid.

This assignment is confirmed in Fig. 2 which shows a fibril that was negatively stained for only a portion of its length. The continuity and phase of the banding pattern across the border region are maintained, in spite of the reduction in contrast.

Although the proposed models for the collagen fibril predict 0·6 D regions (B bands) of lower density than the A bands, the current study of unstained fibrils shows the reverse to be true. Our interpretation is based on the fact that, in the absence of coherent scattering, the relative intensities in the electron image are simply a function of the mass/unit-area of the specimen and are relatively independent of the scattering species[11]. As the profiles show no significant difference in thickness from one band to the next, one can suppose that the unstained pattern (Fig. 1*b*) truly represents the longitudinal density distribution in the fibril. The Na-PTA stain, furthermore, serves merely to emphasize the natural band densities rather than to reverse them.

It is possible to reconcile the three dimensional models with the unstained density distribution in at least two ways. First, if the length of the tropocollagen molecule were 4·6 D (about 3000 Å) instead of 4·4 D and the hole regions were 0·4 D, the densities would conform to the observed pattern. There then would be five 0·6 D dense regions and four 0·4 D "hole" regions per equivalent molecular length. Alternatively, a dense material can be supposed normally to inhabit the 0·6 D hole regions and be replaced by or bind Na-PTA during the staining. Quantitative determinations of the mass

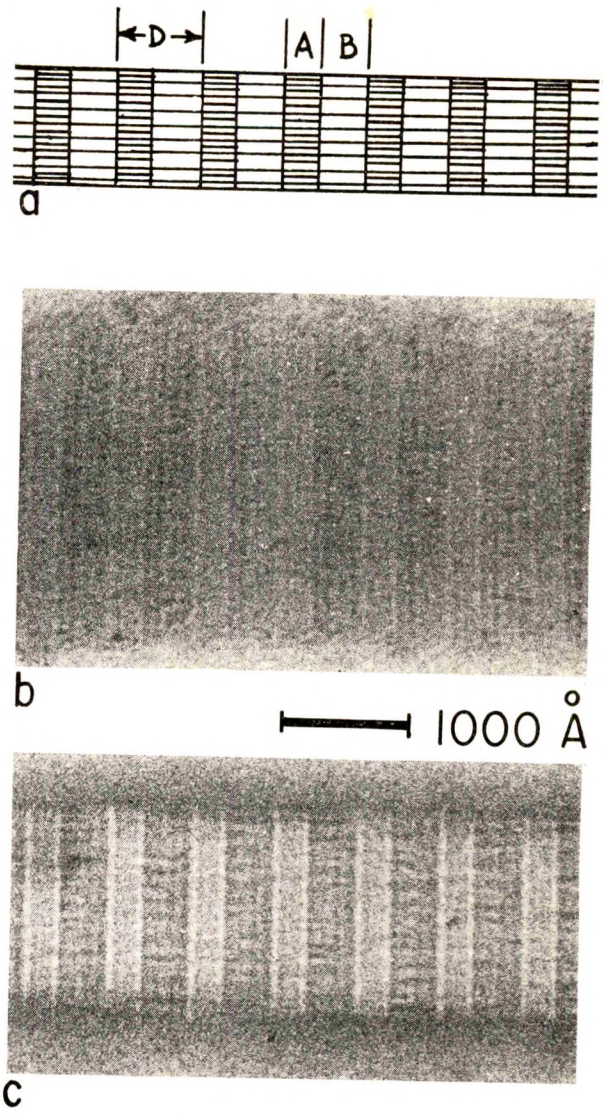

Fig. 1. *a*, Simplified qualitative representation of the density pattern predicted by the currently accepted models for the collagen fibril. *b*, Electron micrograph of an unstained collagen fibril from a rat Achilles tendon. Note the larger dense "B bands" and lighter "A bands", contrary to the predictions of the current models. *c*, Rat tail collagen fibril "negatively" stained with Na-PTA (also typical of negatively stained Achilles tendon fibrils). The correspondence of the two banding patterns suggests that a reversal in contrast does not occur with the stain, except at the margins of the fibril.

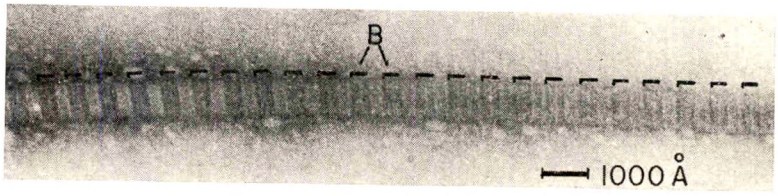

Fig. 2. A portion of a tendon fibril that was "negatively" stained along the left hand half and unstained on the right. This was accomplished by exposing half of a prepared unstained grid to the Na-PTA solution and choosing a fibril that crossed between the stained and unstained regions. The continuity and phase of the banding pattern across the micrograph are emphasized by the brackets adjacent to the B bands.

density along the unstained native fibril are being undertaken and should serve to distinguish these possibilities and refine a better model.

Axial Elements in Plant Meiotic Chromosomes

THE importance of the synaptonemal complex (SC) has been confirmed by its regular occurrence in sexually reproducing plants and animals. In spite of the regular presence of elements of the SC in chiasmatic as well as in achiasmatic[1] meiosis, in haploids, diploids and triploids[2] its precise function is uncertain. It is a matter of conjecture that the SC serves alternately or simultaneously as a mechanism for synapsis and/or recombination. It is almost certain, however, that the SCs are not essential to recombination itself (that is they are not present in prokaryotes and do not accompany somatic crossing over[3]) but are required for the more regular and extensive exchange at meiosis.

Anthers of the diploid lily (variety Enchantment Orange) were fixed with glutaraldehyde followed by OsO_4, essentially as described by Ledbetter and Porter[4]. Thin sections were cut on a Porter Blum microtome, stained with uranyl acetate and lead citrate and viewed with a Siemens Elmiskop I at 80 kV. Transverse sections through the SC of fifty-eight nuclei at meiotic prophase with a synizetic knot of the chromosomes[5] have revealed the bipartite nature of the lateral as well as of the central elements (Fig. 1). The typical arrangement is that of a pair of bipartite lateral elements separated by a bipartite central element. The diameter and arrangements of individual elements observed in transverse sections are compatible with those observed in the same experimental material through longitudinal sections (Fig. 2).

After premeiotic DNA replication, the two axial elements of the sister chromatids lie side by side. In most of the material studied earlier, each individual chromosome seems to consist of one chromatid. This is because of the compact nature of their association due to the presence of protein rich substances. In haploids of *Petunia* and *Antirrhinum* at leptonema, I have found axial elements which are bipartite in agreement with earlier reports[3,6,7].

After replication, and because of the characteristically compact organization of axial elements, segregation of chromatids may not take place in individual sister chromatids until the SC is organized[8,9]. This agrees with the long established finding that four-strand crossing over takes place at pachynema. At pachynema (synizesis[10]), "tetrads of lateral elements"[3] have been observed from single SC (Fig. 1). The cores in bivalents of crayfish spermatocytes were reported to consist of five strands[11]. In cross-section there were two strands on each side of a central element. Presumably the complex represented the two chromatids joined by a fifth element which occurred at the interface between the homologous chromosomes.

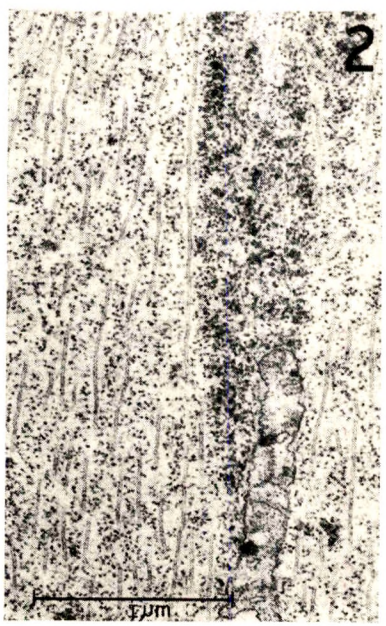
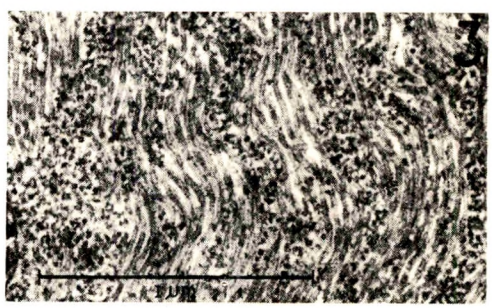
Extensive System of Microtubules in the Ovariole of *Dysdercus fasciatus* Signoret (Heteroptera: Pyrrhocoridae)



MICROTUBULES are especially interesting cell organelles because important intracellular functions are continually being attributed to them which can often be related to their patterns of distribution. These proteinaceous tubules, 180–300 Å in diameter, occur in plant[1] and animal cells[2], mostly in small numbers. Using material fixed with glutaraldehyde and stained with uranyl acetate and lead citrate, I have found that in the ovarian trophic core and nutritive cords of the bug *Dysdercus fasciatus* (Fig. 1) microtubules occur in similar high densities (Figs. 2, 3 and 4) to those in some nerve axons[3] and specialized structures of Protozoa[4]. In a longitudinal section of the trophic core, they cover an unusually large area (up to 350 × 80 μm). Their external diameter is 270 Å.



The microtubules in the trophic core and nutritive cord run longitudinally and roughly parallel (Fig. 2). In the nutritive cord and centre of the trophic core, they are straight in longitudinal section, but elsewhere in the trophic core, they form flow-like patterns around the trophocytes (Fig. 3). The microtubule density is roughly constant throughout the trophic core and nutritive cord, but slightly less in the latter, for the tubules are roughly 1000 Å apart in both tissues, but 3000 Å apart in the nutritive cord (Fig. 4). Ribosomes are always seen between microtubules. The tubules form bundles in the posterior part of the trophic core and in the nutritive cord (Fig. 3), and between these bundles are ribosomes, glycogen granules and mitochondria (Figs. 2 and 3). The two most important roles of microtubules are thought to be in guiding cytoplasmic movement[5] and in intracellular structural support (unpublished results of J. R. Gibbins, L. G. Tilney and K. R. Porter).

In *Dysdercus*, the nutritive cord may be 3 mm long. It is surrounded by columnar follicle cells which become squamous as the oocytes grow. I suggest that because of this change of shape and oocyte growth, a longitudinal tension develops which could constrict the nutritive cord. It therefore needs support and in this need is comparable with long, thin structures such as axopodia, cilia and flagella which protrude into the surrounding environment. Here support is provided by geometrically arranged microtubules and in cilia and flagella the 9 + 2 arrangement also plays an important part in movement. The nutritive cord is also comparable with cells under permanent stress, such as certain plant cells and precuticularized insect epidermal cells which do not protrude and therefore do not need such a rigid support. The microtubules found in these cells may also serve a supporting function[6,7]. I suggest that in the nutritive cord of *Dysdercus* the microtubules represent an intermediate situation. They support the nutritive cord but have a more random arrangement than in protruding structures or motile systems, a greater density than insect or plant epidermal cells, and they cover a much greater area.

The oocytes differentiate in series, the largest and oldest being most distal. The distance from an oocyte to the germarium therefore increases during development and the nutritive cord must lengthen accordingly. During adult life, this growth can be by a factor of × 15 (from 0·2–3·0 mm). Throughout its length, the diameter of the cord (30 μm) is approximately constant, as is the density of microtubules. This means that the tubules must either lengthen individually (which seems most likely) or multi-

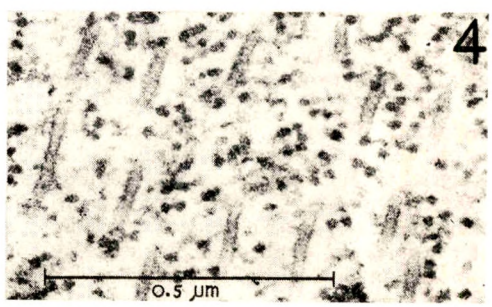


Fig. 1. Diagrammatic representation of the anterior part of the ovariole (not to scale). Fig. 2. Microtubules, ribosomes, glycogen granules and mitochondria in the trophic core. Fig. 3. Microtubules in simple flow-like patterns between trophocytes. Fig. 4. Showing size and spacing of microtubules.

ply. They may therefore serve both as general support for the cord and as important elements in its morphogenesis.

The trophic core is a large, syncytial area which, like the nutritive cord, needs internal support, to prevent invasion or obliteration by disintegrating posterior trophocytes.

In the absence of resisting structures such as microtubules, these cells could wander, for they are not attached to a basement membrane, or interconnected by desmosomes. Further, in telotrophic ovarioles, nutritive material passes from the germarium to the oocytes[8]. Without some internal support disintegrating cells might be swept inwards with this cytoplasmic movement.

In a longitudinal section of the trophic core, microtubules form three zones. They are cut in transverse section at the edge of the core, longitudinally in the centre and obliquely in the intermediate region. It is not yet clear whether these are distinct populations or one system of tubules which bend, but these observations nevertheless confirm that the tubules are the principal strengthening material within the tissue.

Anterior to the trophic core is a ligament which suspends the ovariole in the abdominal haemolymph. During oocyte development this ligament is subject to longitudinal stress. In the trophic core, the central zone of microtubules may help the ligament to sustain this tension while the peripheral zones may function in maintaining the cylindrical shape of the core.

Microtubules are also thought to be involved in protoplasmic streaming and it seems likely that the microtubules of *Dysdercus* could serve this function in addition to support. Indeed, this might be their most important function, for in the trophic core and nutritive cord, the microtubular bundles could act as boundaries of channels through which nutritive substances pass to oocytes. They could thus play a very large part in oocyte development and the importance of not allowing the trophic core to be invaded by trophocytes would then become clear.

MacGregor and Stebbings[9] report a massive microtubule system in *Notonecta* ovaries and it therefore seems likely that extensive microtubule systems will soon be recognized as an important characteristic, both of telotrophic ovarioles and cytoplasmic masses in general.

I thank Professor A. Graham for departmental facilities, Dr E. A. Robson for much helpful advice and discussion and the Science Research Council for a postgraduate studentship.

Localization of Legumin and Vicilin in Bean Cotyledon Cells using Fluorescent Antibodies

SUBCELLULAR fractions of bulked protein bodies isolated from the storage tissues of seeds contain several or many types of protein[1–3], but in general it is not known whether this diversity occurs within an individual protein body, or whether the different proteins are deposited in separate compartments during seed maturation. Immunofluorescence techniques have enabled us to resolve this question in respect of the subcellular distribution of legumin and vicilin, two important globulins stored in the cotyledons of many legumes[4–6].

Fluorescent antibodies were prepared, using as antigen mixed legumin and vicilin extracted from immature seeds of *Vicia faba* L. variety Sharpe's Conqueror, and purified by repeated ammonium sulphate prepicitation, dialysis and molecular sieve chromatography. Rabbits were hyperimmunized by subcutaneous injections, and homologous antibodies were adsorbed directly from antisera onto columns of *V. faba* globulins cross-linked by treatment with glutaraldehyde[7]. Eluates[7] were concentrated, and labelled with fluorescein isothiocyanate (FITC)[8] to provide a mixed conjugate from which FITC-anti-legumin and FITC-anti-vicilin could be isolated. Further purification was required because anti-legumin has been reported to cross-react with vicilin and anti-vicilin with legumin[5,9], a result which either confirms that the two antigens have amino-acid sequences[6] and thus some antigenic determinants in common, or suggests that the antigen preparations used were impure. Like other workers using isoelectric precipitation[4–6,10], we found difficulty in preparing pure samples of vicilin and legumin. But by centrifuging samples of the FITC-mixed conjugate which had been treated with either excess legumin or excess vicilin preparations, supernatants containing only antibodies that were demonstrably incapable of cross-reacting were obtained. Double diffusion tests confirmed that although the conjugates had sustained reduction in titre they consisted only of highly specific FITC-anti-vicilin or FITC-anti-legumin. The mixed or these monospecific conjugates were applied singly or sequentially, during 1–7 h periods at 37° C, to approximately 10 μm transverse sections of bean cotyledons, cut in a cryostat and representing various developmental stages. The cotyledon tissues had been fixed in 2·5 per cent glutaraldehyde and subsequently stored in cold buffer containing hibitane. No non-specific fluorescence could be detected in control sections pretreated with unlabelled antisera (Fig. 1).

Fluorescence microscopy indicated that the synthesis of vicilin precedes that of legumin in the developing cotyledons. Cells located in and close to the vascular strands, or in a paradermal zone underlying the abaxial epidermal transfer cells[11], become labelled earlier in seed maturation than most others. At the subcellular level, legumin and vicilin are clearly located within protein bodies (Figs. 2–6). The identification of the protein bodies and the presence in them of storage globulins have also been checked by electron microscopy using ferritin-labelled antibodies. Some protein bodies were not completely filled with the antigens (Fig. 2), and the distribution of fluorescence often paralleled the distribution of the marginal deposits of electron-dense material considered to be protein and seen in ultrathin sections of developing protein bodies of *V. faba*[12]. Enhancement of fluorescence after sequential staining with FITC-anti-legumin and FITC-anti-vicilin (in either order) showed that most reactive protein bodies contained both globulins (Figs. 4 and 5). A very few, perhaps transient developmental stages, were found to contain vicilin but no detectable legumin (Fig. 5).

Cells of immature cotyledons contain in addition protein bodies which apparently lack both legumin and vicilin (Figs. 3–6) and which cannot be induced to fluoresce even after freezing and thawing or treatment with acetone or Triton-X100. Sequential staining with mercuric-bromo phenol blue[13] or acid fuchsin at low *p*H[14] (Fig. 6) reveals that proteins are nevertheless present in them. They are found at most stages of development, including the early period when vicilin is sparse and legumin is but a trace component. Because some legumes begin to accumulate albumins before their globulins[15,16], these non-fluorescent protein bodies may represent a type that specializes in the storage of albumins; alternatively

Original photographs on high speed Ektachrome using Zeiss UG 1 exciter filter and −65 and 41 barrier filters. (1) Control (see text)—no green fluorescence. (2) and (C) Reaction with FITC-labelled mixed anti-legumina and anti-vicilin. Both of the arrowed protein bodies are large enough to have been cut open during sectioning; one (2) evidently contains antigen(s), the other (3) does not. Both figures include numerous smaller, labelled protein bodies.

Figs. 4–6. Sequential staining of the same field of view with: (4) FITC-anti-legumin; (5) FITC-anti-vicilin; (6) acid fuchsin (bright field microscopy). The enhancement of fluorescence as between (4) and (5) is shown by most protein bodies (for example 1 compared with 1+v) and indicates the presence of both legumin and vicilin. It is much more obvious in the original colour photographs. v Represents a protein body containing no detectable legumin. Other protein bodies (such as those encircled in 6) do not react with either antibody. s, Starch grain. (Figs. 1, 4, 5 and 6, ×350; Figs. 2 and 3, ×200.)

they might be albumin-containing precursors, destined to receive legumin and vicilin at a later stage. It is intended to clarify this point through the use of labelled anti-albumin antisera, and it should be possible to determine whether the cohabitation now established for legumin and vicilin extends further to include albumins.

Are Endogenous Gibberellin-like Substances involved in Floral Induction

The concentration of endogenous gibberellin-like substances has been reported to increase in cold-requiring plants during exposure to a low temperature[1–3]. Synthesis of gibberellin is also known to be blocked by certain growth retardants, some of which inhibit flowering[3–6]. Thus there is increasing evidence for an involvement of gibberellin in floral induction. In studies with broccoli (*Brassica oleracea* variety *italica*), it was found that low temperature enhanced flowering and that (2-chloroethyl)trimethylammonium chloride (CCC) did not retard floral induction, but that 1,1-dimethylaminosuccinamic acid (B995) did[7,8]. Although both these compounds are considered to be growth retardants, B995 has not been shown to affect the endogenous concentration of gibberellin. It was therefore important to determine the effects of CCC and B995 on this concentration in broccoli in relation to floral induction.

Broccoli plants were treated twice with CCC as a soil drench at a concentration of 0·5 g/plant to give a total of 1 g/plant. B995 was applied as a spray in a concentration of 2,500 p.p.m. These retardants were applied 35 and 46 days after seeding in a 24°–27° C growth chamber (1,800 foot candles for 16 h daily). On the day after the last treatment with these retardants plants were transferred to a 5° C chamber (350 foot candles for 16 h daily) for 3 weeks. Control plants were grown continuously at 24°–27° C. After the time at 5° C treated and control plants were collected and frozen to await analysis for gibberellin. Nine plants which had received each treatment followed by subjection to cold were returned to a growth chamber at 24°–27° C for a further week. These and control plants were then examined with respect to growth and flowering.

Plant tissue to be analysed for gibberellin-like substance was homogenized in 90 per cent aqueous methanol (1 : 5 w/v). After extraction at −20° C for 24 h the homogenate was filtered and extraction was repeated on the residue. The residue was then extracted with half the volume of methanol used in the first extraction. Combined methanol extracts were flash evaporated until only the aqueous phase remained. The evaporating flask was rinsed several times with water and 5 per cent $NaHCO_3$. This aqueous solution was centrifuged to remove precipitated substances. The supernatant was partitioned five times with equal volumes of chloroform to remove pigments and lipids, and the aqueous phase was adjusted to *p*H 3·0 and partitioned three times with ethyl acetate. Combined ethyl acetate fractions were evaporated to dryness.

The gibberellins in the ethyl acetate residues were chromatographed on silica gel partition columns by the method of Powell and Tautvydas[9]. The lettuce hypocotyl bioassay was used to detect gibberellin-like substances[10]. Each fraction from the column of silica gel was bioassayed in triplicate, and all samples were run in duplicate.

None of the plants grown at 24°–27° C initiated floral primordia. At 5° C all those treated with CCC flowered

and 88 per cent of control plants flowered. Only 33 per cent of plants treated with B995, however, were induced to flower at 5° C.

Fig. 1*A* shows that plants grown continuously at 24°–27° C contained little gibberellin-like substances. The content of these substances seems to be increased by treatment at 5° C (Fig. 1*B*). There are also zones of activity present in plants kept in the cold which are not readily observable at 24°–27° C. This suggests a qualitative change in gibberellin-like substances when plants were subjected to cold temperatures.

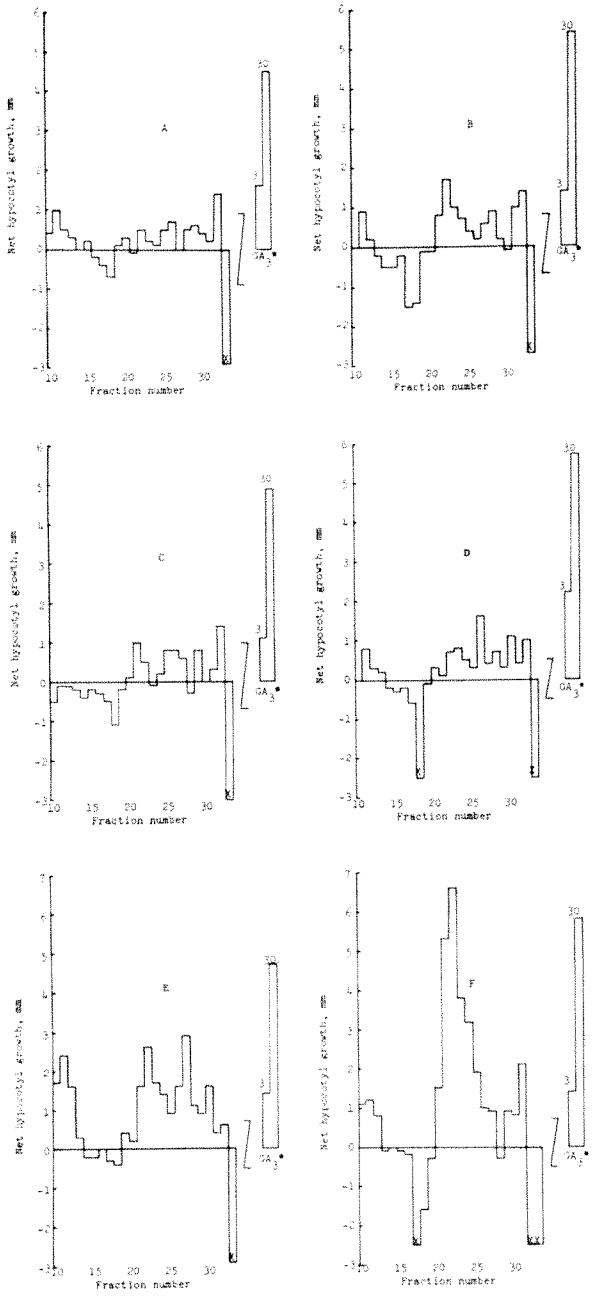

Fig. 1. Methanol extractable gibberellin-like substances in Watham 29 broccoli. Plants were (*A*) grown continuously at 24°–27° C; (*B*) exposed to 5° C for 3 weeks; (*C*) treated with CCC and grown continuously at 24°–27° C; (*D*) treated with CCC and exposed to 5° C for 3 weeks; (*E*) treated with B995 and grown continuously at 24°–27° C, and (*F*) treated with B995 and exposed to 5° C for 3 weeks. Gibberellin-like substances were detected by lettuce hypocotyl bioassay after column chromatography. Weight of tissue extracted was: (*A*) 297 g; (*B*) 352 g; (*C*) 397 g; (*D*) 345 g; (*E*) 284 g; (*F*) 324 g. X, Germination inhibited; Z, spread of controls. * ng of gibberellic acid/tube.

The influence of CCC on endogenous gibberellin-like substances is shown in Fig. 1*C* and *D*. The concentration in plants grown continuously at 24°–27° C is low (Fig. 1*C*), and there seems to be no increase at the low temperatures (Fig. 1*D*). The concentration of endogenous gibberellin-like substances seems to be reduced slightly by CCC when the weight of tissue extracted and activity present are compared with those of control plants. The number of gibberellin-like substances present in plants treated with CCC at 24°–27° C (Fig. 1*C*) is comparable with those present in untreated plants at 5° C (Fig. 1*B*) except for activity in fraction 10. This suggests that qualitative changes did not occur during cold treatment but rather that the concentration present at 24°–27° C was too small for detection.

The most marked effect on endogenous gibberellin-like substances—an increase at both temperatures—was observed after treatment with B995 (Fig. 1*E* and *F*). Plants grown continuously at 24°–27° C and treated with B995 (Fig. 1*E*) had four prominent peaks of activity. But only three peaks were present at 5° C (Fig. 1*F*). The very large peak from fraction 20–26 (Fig. 1*F*) could have been a combination of the two peaks present at 24°–27° C (Fig. 1*E*). There was a large increase in gibberellin-like substances in plants treated with B995 and subjected to low temperature.

These results suggest that gibberellin-like substances as revealed by this bioassay are probably not involved in floral induction of broccoli. The apparent increase in these substances at 5° C may be a result of decreased growth. It is also clear that B995 does not block the synthesis of gibberellin-like substances in this tissue, which is in agreement with earlier reports[5,6]. B995 therefore must inhibit floral induction through its effects on other processes or as a consequence of there being too high a concentration of gibberellin. Our findings are somewhat paradoxical, for the action of B995 is often reversed by exogenous gibberellin. CCC may have had a slight inhibitory effect on the synthesis of gibberellin-like substances, but not on floral initiation. Thus the use of these two compounds should provide more information about the physiology of flowering.

Competitive Adsorption of Phosphate with Polygalacturonate and other Organic Anions on Kaolinite and Oxide Surfaces

Some plants are known to remove phosphate readily from soils low in phosphate. It is likely that root excretions and microorganisms greatly modify the chemical environment in the rhizosphere and this may result in the more

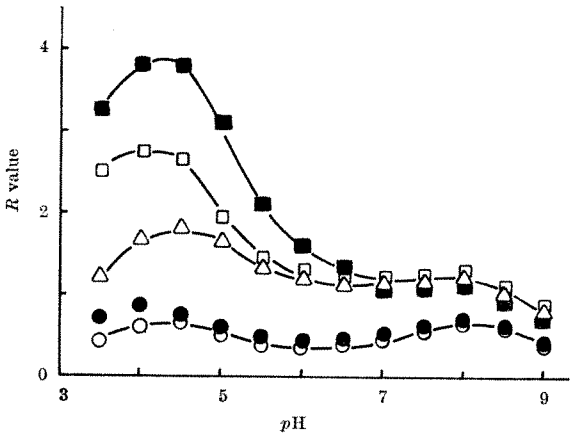

Fig. 1. The relationship between pH and the competitive ability (R) of polygalacturonate (PGA) and galacturonate to desorb phosphate from kaolinite. Initial P, $6{\cdot}45 \times 10^{-6}$ M; ○, 0·0001 per cent PGA; △, 0·001 per cent PGA; □, 0·01 per cent PGA; ■, 0·1 per cent PGA; ●, 0·1 per cent GA.

ready displacement of the adsorbed phosphate from soil colloids. Organic compounds found in the root exudates of several plants, reviewed by Rovira[1], include many organic acids known to form strong complexes with metal ions. Examination of the root–soil interface under the electron microscope has also revealed a slimy gel between the root and the soil colloidal particles[2,3], which has been called "mucigel" and is considered to consist of pectic substances, chiefly partially methylated polygalacturonic acids.

We have investigated the effect of organic compounds known to be exuded by plant roots on the adsorption of phosphate by kaolinite, gibbsite and goethite. Kaolinite (0·5 g in 200 ml.) or oxide (0·05 g in 25 ml.) was added to a solution containing either phosphate alone or phosphate and organic anion in combination in 0·01 M KCl, and equilibrated for 24 h at $21 \pm 1°$ C. The various organic compounds tested are shown in Table 1. A synthetic pectic acid–polygalacturonic acid (molecular weight approximately 25,000) was used to examine the possible effect of mucigel. The influence of these organic compounds on the adsorption of phosphate by kaolinite and oxide surfaces was assessed by R which is defined by

$$R = \frac{\text{P adsorbed alone} - \text{P adsorbed in the presence of the organic anion}}{\text{P adsorbed in the presence of the organic anion}}$$

This relationship shows that if no decrease in phosphate adsorption occurs, R is zero and when the organic ion completely stops the adsorption of phosphate, R is infinity.

Table 1. COMPETITIVE ABILITY (R_{max}) OF VARIOUS ORGANIC ANIONS ON CLAY AND OXIDE SURFACES

Anion	pK_1	pK_2	Kaolinite		Gibbsite		Goethite	
			R_{max}	pH at R_{max}	R_{max}	pH at R_{max}	R_{max}	pH at R_{max}
Citrate	3·13	4·76	4·3	4·8	6·00	5·25	0·23	4·25
Tartrate	3·03	4·37	1·5	4·3	0·9	5·25	0·1	4·00
Oxalate	1·25	4·28	7·0	4·0	2·6	5·75	0·1	4·00
Malate	3·46	5·05	1·2	4·5	1·0	5·00	0·1	4·00
Succinate	4·21	5·64	0·2	No max	0·2	5·5	—	—
Malonate	2·85	5·7	1·9	4·5	0·6	5·75	—	—
Lactate	3·86	—	0·2	No max	0·2	No max	—	—
Acetate	4·76	—	0·2	No max	0·2	No max	—	—
PGA (0·1 %)*	3–5		4·0	4·25	1·4	4·0	0·4	4·00
Ga (0·1)†	3·48	—	0·5	4·5	0·8	7·0	—	—

The concentration of KCl was 10^{-2} M. The initial organic anion concentration was $1{\cdot}59 \times 10^{-5}$ M; initial P, $6{\cdot}45 \times 10^{-6}$ M; kaolinite, 0·5 g/200 ml.; oxide, 0·05 g/25 ml.

* The concentration of polygalacturonate was 4×10^{-5} M because molecular weight is approximately 25,000.

† The concentration of α-D-galacturonate was 5×10^{-3} M.

The results (Table 1) show that citrate and oxalate are very effective in decreasing the adsorption of phosphate by kaolinite and gibbsite. On the other hand, malonate, tartrate and malate are moderately effective, while acetate, succinate and lactate hardly decrease phosphate adsorption. Other experiments, not reported here, indicate that the amino-acids α-L-alanine, L-threonine, DL-aspartic acid and L-lysine, found in plant root exudates, also failed to decrease phosphate adsorption on any of the three absorbants.

A significant result is the marked effectiveness of polygalacturonate in decreasing phosphate adsorption (Table 1 and Fig. 1) particularly on kaolinite. It is also interesting that the monomer galacturonate hardly decreased adsorption of phosphate (Fig. 1 and Table 1). A related observation is that the polymer has been found to complex Ca^{2+} whereas the monomer does not[4].

Two other features of these results are worth mentioning although no satisfactory explanations can be given. The first is the observation that for any organic anion R is greatest at a pH which corresponds to the second pK value of the organic acid. For polygalacturonic acid R is maximum at what could be its second pK value. The second is that values of R for the organic anions on goethite are very small compared with the values obtained on kaolinite or gibbsite, but even here polygalacturonate is the most effective anion (Table 1).

The organic anions which are effective in decreasing the adsorption of phosphate by the three adsorbents are those capable of forming chelates containing five and/or six membered rings with metal ions[6–8]. Polygalacturonate, which was as effective, if not more so, than the other chelating agents used, is also known to form stable chelates with metal ions[9,10]. Phosphate is considered to be "specifically" adsorbed on kaolinite and oxides by the formation of a surface complex through ligand exchange of phosphate with H_2O molecules and/or OH^- coordinated with Fe^{3+} (goethite) or Al^{3+} (kaolinite and gibbsite) ions in the surface[11,13]. Detailed studies of the adsorption of citrate have shown that citrate is also specifically adsorbed by these adsorbants[5,14]. Thus, when phosphate and an organic anion are present together, the decrease in phosphate adsorption by an adsorbant must arise from the specific adsorption of the organic anion resulting from competition between phosphate and the organic anion for adsorption sites. Whether an organic anion is capable of decreasing phosphate adsorption or not would be determined by the relative stabilities of the Fe (or Al)–organic anion complex and the Fe (or Al)–phosphate complex.

The marked effectiveness of polygalacturonate in decreasing phosphate adsorption by the three adsorbants indicates that plants may possess a very efficient way of desorbing phosphate from soil colloids at the root/soil interface by utilizing the large concentration of pectic substances in the mucigel around their roots.

Field Evidence for Polarized Light Sensitivity in the Fish *Zenarchopterus*

POLARIZED light perception has never been unequivocally proven in vertebrates except man. An unusually alert human observer can see by inspection the plane of polarization (*e*-vector) in linearly polarized light by virtue of Haidinger's brushes, a faint blue and yellow image of intraocular origin produced by the selective absorption of polarized light by the yellow macular pigment of the fovea. Attempts to demonstrate polarized light perception in other vertebrates have, however, usually failed (for example in birds[1,2]).

Nevertheless, there are actually three previous reports of polarized light responses by teleost fishes[3–5], but none of these was adequately followed up to provide needed additional data or reasonable explanations for certain ambiguous or anomalous experimental results. We now report consistent evidence that the hemiramphid teleost *Zenarchopterus*, a west Pacific half-beak, can have its directional preferences affected by linearly polarized light.

Using SCUBA small specimens of *Zenarchopterus* (*Z. dispar* (Cuvier and Valenciennes) and *Z. buffoni* (Cuvier and Valenciennes)) were placed in a covered flat cylindrical dish and positioned at the focus of an automatic Robot camera directed vertically upward. The azimuth orientation of the fish was photographed every 5 or 10 s. Set on a tripod in 3–5 m of clear calm water the apparatus was screened so that except for a lens aperture the fish could not see the equipment, the observers or landmarks on the bottom (Fig. 1). The upper half of the fish's visual field, however, comprised the surrounding water, its surface and, within the critical angle, the Sun and sky. The behaviour of the fish confined under these conditions was usually calm but responsive.

Table 1*. ORIENTED BEHAVIOUR OF HALF-BEAKS

	(260)	(140)	(146)	(151)	(75)	(512)	(772)

* In each category the upper figure is the mean vector of the fishes' heading; all are significant at the 1 per cent level or better. The lower figure (in parentheses) for each category is the number of heading measurements.

Three experiments were carried out on different individual half-beaks (Table 1). Their oriented behaviour was measured under natural illumination (including sky and water polarization[6]) and under conditions where the polarization pattern was altered by placing a linear dichroic polarizer over the experimental vessel, with its plane of polarization at 0°, 45° and 90° relative to the Sun's bearing in the first two experiments and also at 135° for the third.

Sequences of about twenty-five exposures were made every 10 s in experiments 1 and 2 and every 5 s for experiment 3 for each of the four to five experimental conditions tested. In the longer experiments these were cyclically repeated. Because of initial operational difficulties and different timing intervals the number of observations and duration of each experiment were different (Table 1). Thus more than half of our measurements came from experiment 3.

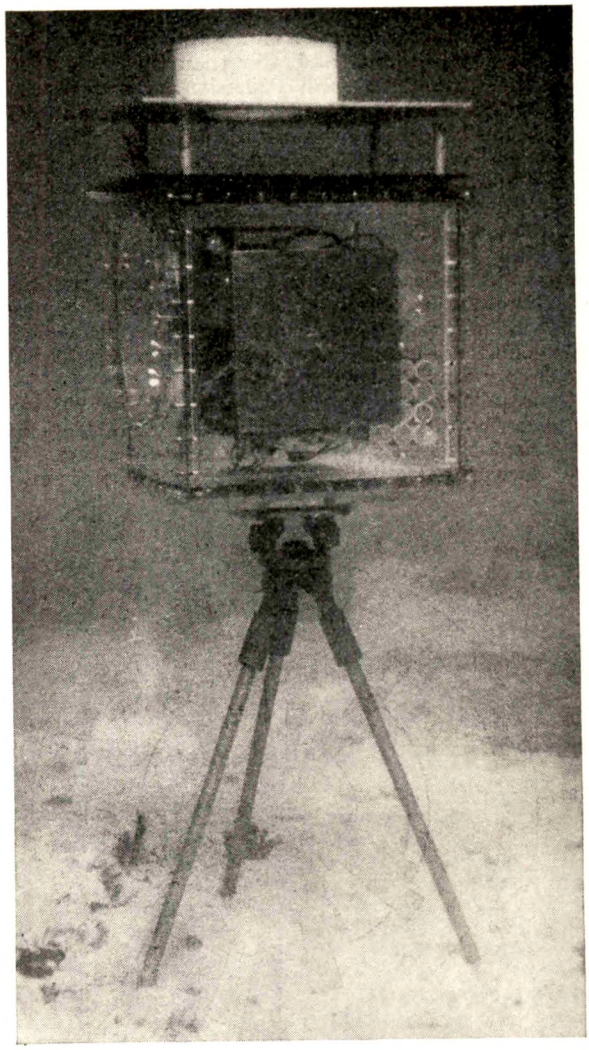

Fig. 1. Underwater experimental set-up. The fish under study (not seen in the photograph) is in a closed transparent vessel inside the white cylindrical screen above. Natural submarine illumination is visible to the animal in the upper hemisphere of its visual field. In most tests this was modified by placing over the white screen a polarizer with its *e*-vector in different specific azimuth orientations. An automatic camera enclosed in the large lucite box recorded the fish's heading at 5 or 10 s intervals.

Each heading, defined as the direction of the anterior end of the fish's longitudinal axis relative to the Sun's bearing, was determined from the film negative with the aid of a projection enlarger. Measured clockwise from 0°, the angles were grouped over 10° sectors centred around 0°, 10° and so on to 350°. Appropriate statistics were used for analysing their circular distribution[7] as well as chi-square techniques where useful. Mean vectors were calculated, their significance being tested with z and that of differences between them with F.

Only in experiment 3 and the pooled total data were mean vectors significant at the 1 per cent level obtained for all conditions tested. These mean vectors, the n's on which they are based and the conditions tested are presented in Table 1. The circular distributions for the total data are plotted in Fig. 2.

In experiment 3 all five conditions tested (Table 1) yielded mean vectors significant at the 1 per cent level or better. Natural illumination evoked menotactic orientation with a mean vector at 123°; this is not significantly

different from a direction of 138°, the mean for the 90 vector test. Vector directions for both 0° and 45° (but not that for 135°) differed at better than the $P < 0{\cdot}05$ level from that under natural illumination. Comparisons between mean directions for the four *e*-vector orientations tested reveal an interesting dichotomy. The mean directional responses to polarization planes differing by 90° (0°–90°, 45°–135°) are indistinguishable, yet those provoked by *e*-vectors differing by 45° (0°–45°, 45°–90°, 90°–135°, 0°–135°) are sharply distinct.

Pooling of all field measurements yields four mean vectors all indicating significantly different orientation behaviour at better than the 1 per cent level. Comparison of the differences between the six possible pairs among the four conditions tested shows that five are significant at the 2·5 per cent level or better.

Thus polarization planes at 0° or 45° or 90° evoke significantly different orientation patterns. The fishes also orient differently with 0° *e*-vector or 45° *e*-vector than they do with natural illumination alone. The directional pattern with 90° *e*-vector (Fig. 2*D*) is, however, like that with just natural illumination (Fig. 2*A*). This implies behaviour which is affected by the polarization of natural illumination because the *e* vector is perpendicular to the Sun's vertical in both the sky and the sea[8,9]. Furthermore the same orientation with 90° polarization and natural illumination indicates that the other different mean vectors with and without the polarizer do not result just from intensity reduction by the dichroic filter.

Although we cannot yet assess the relative importance of the Sun's position, sky and water polarization or other possible factors in the menotactic orientation of *Zenarchopterus*, our data do show that linearly polarized light significantly affects this behaviour. Furthermore, the fact that the 90° position of the polarizer would reinforce the degree of sky and water polarization, but not change its pattern in the great circle coincident with the Sun's bearing, supports the hypothesis that the fishes' usual azimuth orientation is a function of the Sun's bearing as well as the polarization pattern. This is further sustained by

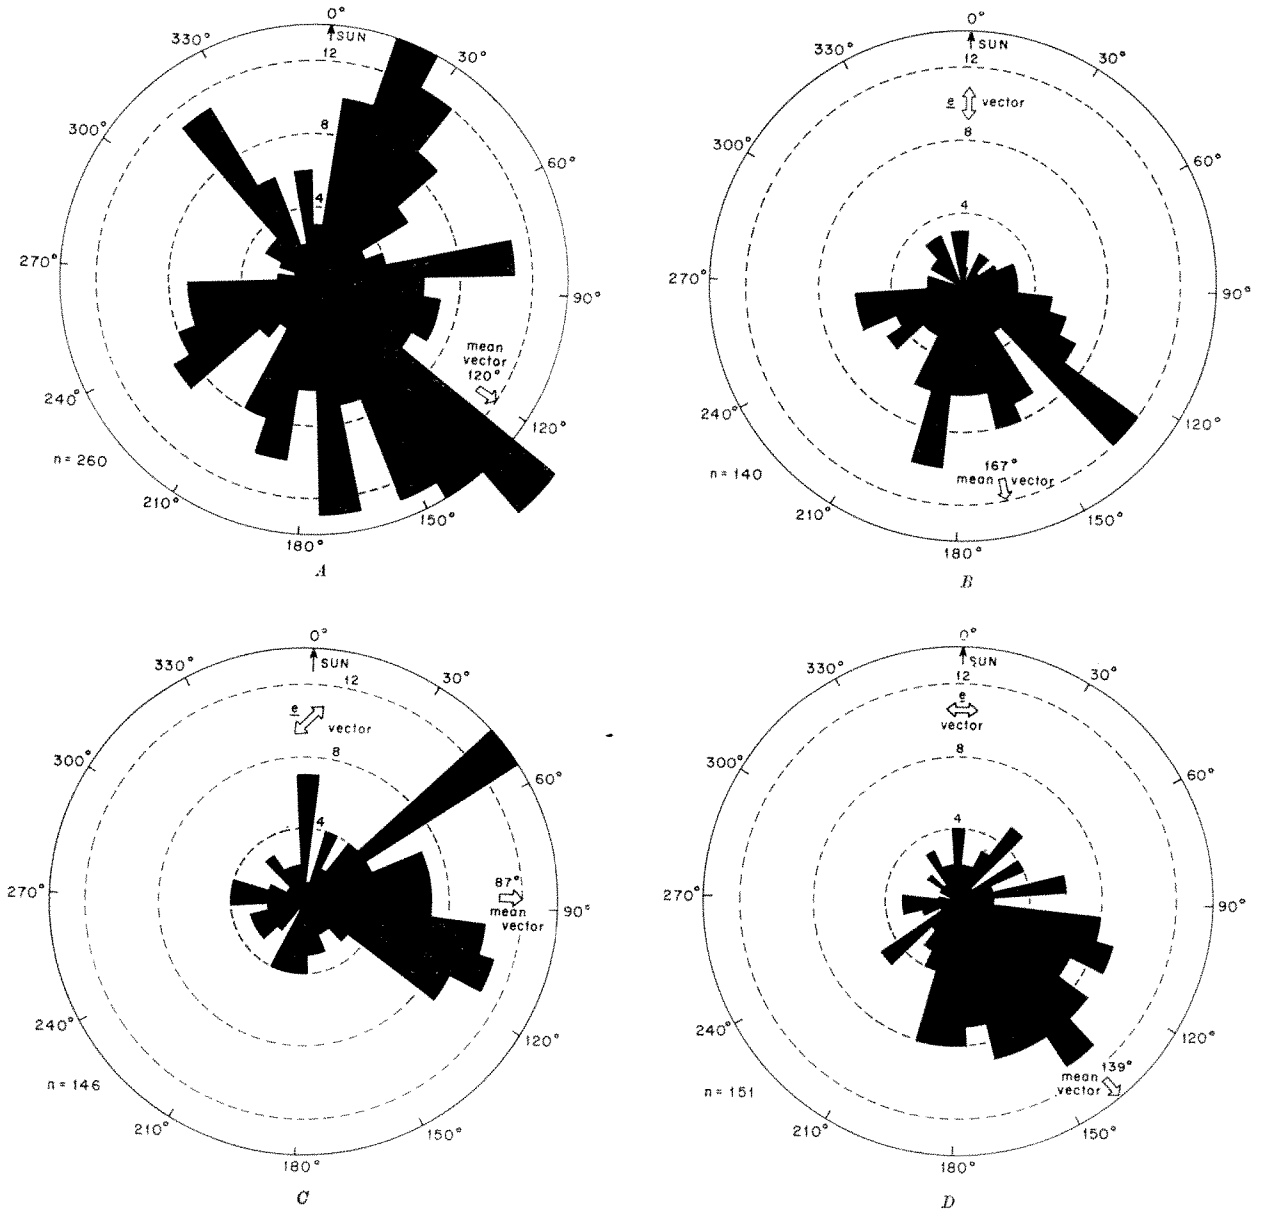

Fig. 2. Pooled results of underwater experiments on azimuth orientation of *Zenarchopterus*. *A*, Under natural illumination; *B*, same but with added polarizer having its *e*-vector at 0° (relative to the Sun's bearing); *C*, same but with *e*-vector at 45°; *D*, same but with *e*-vector at 90°. The radial coordinate represents number of observations grouped in 10° intervals around the circle. Mean vectors for each condition are shown by the single-headed broad arrows.

laboratory experiments on *Zenarchopterus* to be reported elsewhere; they demonstrate polarotactic behaviour patterns quite distinct from the menotactic orientation observed in the field.

To understand the interaction of such polarotactic and menotactic orientation[9], field experiments must be carried out at various times of day with different geographical Sun's bearings. Pre-sunrise and post-sunset experiments might isolate the influence of natural *e*-vector patterns from the direct effect of the Sun's rays, but further study would be required of the anomalous submarine polarization patterns known to be present at dusk[8,10,11].

The question of the mechanism of *e*-vector perception in a teleost is intriguing. It has been suggested that extraocular dichroic structures might provide the necessary analyser (personal communication from T. Kuroki, 1968), yet the fresh skin and skull over the midbrain region of *Zenarchopterus* where there is a translucent "window" do not show significant dichroism which might modulate a pineal or neighbouring midbrain photoreceptor.

Fishes, of course, lack rhabdoms whose specific fine structure relative to the orientation of visual pigment chromophores underlies polarized light sensitivity in arthropods and cephalopods[9,12–17]; nor do they have the macula lutea thought to be responsible for Haidinger's brushes in man.

At the suggestion of Dr Gary Bernard of the Yale Ophthalmology Department we are investigating the possibility that twin cones, which are of unknown function but occur in the retinas of a number of teleosts[18,19], might provide an analyser mechanism. Although the fine structure of their receptor membrane is quite different from that of a rhabdom their ordered arrangement in rectangular or oblique patterns in certain fishes[20] is strikingly reminiscent of the regular mosaic of rhabdomeres and rhabdoms of arthropod compound eyes[21]. Thus far light microscopic sections of *Zenarchopterus* retina prepared in collaboration with Mrs Mabelita Campbell have shown that twin cones are prominently present in regular array. It remains to be shown whether they may provide any basis for *e*-vector discrimination. Experiments to test this are in progress with Dr Haruo Hashimoto.

This research was supported by a grant from the National Geographic Society and by a US Public Health Service grant. We thank Mr Robert Owen and Mr Peter Wilson, of Koror, Palau, US Trust Territory of the Pacific Islands, for providing facilities for these experiments, Mr Howard Ozer for assistance in carrying out the work, Dr Donn Rosen for identifying the fishes used, and Professor Arthur Hasler for critical comments on the manuscript.

Retention of a Conditioned Avoidance Response after Metamorphosis in Mealworms

METAMORPHOSIS of holometabolous insects involves extensive reorganization of their nervous systems[1,2]. In spite of such changes, behavioural modifications can be demonstrated at the adult level after manipulations in the larval stage[3–5]. For example, the adult reactions of *Nemeritis* and *Drosophila* to chemical cues have been altered by exposure to these cues during the larval stage[3,4]. One limitation of these experiments, as Thorpe points out, is that the behavioural modification cannot be assessed directly in the larval stage. Using a more formal conditioning procedure, Borrell du Vernay[5] found that *Tenebrio* trained to discriminate between surfaces and thus avoid shock in the larval stage showed subsequent savings in relearning the discrimination as adults. Unfortunately, this study did not include controls for such variables as sensitization to shock and familiarization with the test situation.

We report here an unambiguous demonstration of retention though metamorphosis. The first of our two experiments showed that either larval or adult *Tenebrio molitor* L. could learn a passive avoidance task; the second demonstrated that responses learned by larvae persisted in adults.

The training chamber in both experiments was a uniformly illuminated lucite box 5 × 7·5 cm in size. The floor was divided into two parts: one with a lucite surface and the other with a copper surface. Copper wires, 7 mm apart, were suspended 1 mm above the copper surface. When an insect bridged the space between the wires and the underlying copper surface, it received shock until it returned to the lucite surface. Insects, selected randomly from stock culture, were isolated for at least 7 days and then individually introduced on to the lucite (safe) surface. The interval between introduction to the lucite surface and the first movement to the copper surface was termed the response latency; an increase in response latency during successive days of training was a measure of learning. Each daily session ended when an insect remained on either surface for 30 min. Fig. 1 summarizes the results from our first experiment. On day 1, for both larvae and adults, the copper surface was not electrified, thereby providing a measure of the preferences of untrained insects. The latency of the first response (from lucite to copper) did not exceed 200 s for larvae or 40 s for adults—all animals had a pretraining preference for the copper surface; the adults and larvae spent 89 and 89·5 per cent respectively of the total time in the chamber on the copper.

On subsequent training days (days 2–6 for larvae and days 2–7 for adults) the copper surface was electrified. As Fig. 1 shows, the latency of the first response increased significantly during training. This increase, however, need not represent only passive avoidance conditioning, but it could be attributed in part to habituation effects or to the fact that the animal sampled shock without actually crossing to the copper surface. During the next 2 days we investigated these alternatives.

On the day after training, no shock was given, but both larvae and adults remained on the lucite surface for the full 30 min (Fig. 1): apparently sampling did not account for the increase in response latency observed during training. Each animal was then left in the apparatus until it had explored both surfaces and remained on

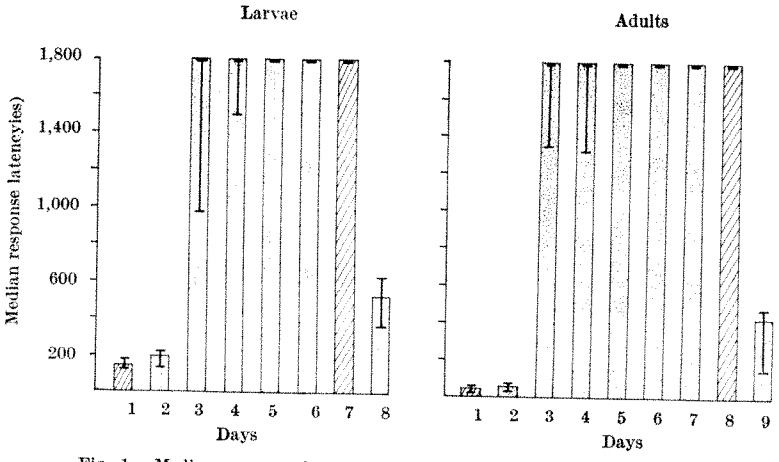

Fig. 1. Median response latency for the first movement of larval and adult *Tenebrio* from lucite to copper surface. Interquartile intervals are indicated by brackets. Ten animals comprised each group. Stippled columns, copper surface electrified; hatched columns, copper surface not electrified.

one of them for 60 min. On the next day, the copper surface was electrified again, and response latencies decreased sharply (Fig. 1). Because the pattern of preference built up during training had been reversed by 1 day without shock, habituation to the lucite surface could not possibly explain the increase in response latencies during training. It is most probable that increased latency reflects true conditioning.

Our second experiment involved the same training procedure, but each animal was trained as a larva and tested as an adult. Control groups were used to determine the degree to which conditioning, habituation, sensitization and/or familiarization in the training sessions with larvae contributed to the behavioural modifications following metamorphosis. One experimental and two control groups were used. The experimental group (trained) consisted of larvae that were trained for at least 10 days, allowed to pupate and tested for retention 3 days after the adult moult. One control group (no treatment) consisted of larvae that were allowed to explore the testing apparatus in the absence of shock, allowed to pupate and tested as adults. The other control group (non-contingent shock) consisted of larvae that were exposed to non-contingent shock in the training chamber, allowed to pupate and then tested as adults. In the non-contingent shock procedure, larvae were exposed to shock-on and shock-off for approximately the same periods of time as were larvae in the trained group, but a lucite barrier prevented movement; they were transferred from one surface to the other by hand.

Retention in adult beetles was measured by two criteria: (1) duration of first period on the safe surface (avoidance latency), and (2) number of errors before the beetle remained on the safe surface for 30 min (trials to learn). On both indices (Table 1), the trained group performed significantly better than either of the control groups: relative to the controls, the trained group showed longer avoidance latencies ($P < 0.01$) and fewer trials to learn ($P < 0.01$). (The Mann–Whitney U two-tailed test was used.)

Persistence of behavioural modification through a moult is not a new idea, as indicated by previous studies[3–6]. Our present study has shown that neither sensitization nor habituation explains retention following a moult. It is more significant that persistence of a specific conditioned response survives the extensive reorganization of the central nervous system during the pupal stage. Implicit in these data, and in need of further investigation, is the probability that storage of information occurs in specific portions of the central nervous system which retain their integrity through the pupal and imaginal moults.

In either larva or adult, learning to avoid aversive situations is of obvious advantage to the individual insect; certainly such behavioural plasticity would be favoured by natural selection. In this kind of learning, the general exploratory tendencies of the insect are inhibited by a set of learned clues. The fact that the inhibition persists not only within a single instar but also across the pupal stage suggests that each adult will tend to remain in the area which was most favourable for its own larval growth. Thus adult habitat preferences are biased by larval experience. This "place learning" is a conservative phenomenon, reinforcing the isolation of those local populations which are concentrated within the more favourable niches of a heterogeneous environment. Place learning could play a part parallel to and/or complementary with the preimaginal conditioning reported by Thorpe and Jones[3].

Table 1. MEDIAN AND INTERQUARTILE RANGE OF AVOIDANCE LATENCY (S) AND TRIALS TO LEARN IN ADULT *Tenebrio* PREVIOUSLY TRAINED IN THE LARVAL STAGE

Group	*n*	Avoidance latency		Trials to learn	
No treatment	25	41 (33–49)		3 (2–4)	
			$P < 0.01$		$P < 0.01$
Conditioned	25	1,800 (1,800–1,800)		0 (0–0)	
			$P < 0.01$		$P < 0.01$
Non-contingent	31	83 (15–204)		3 (2–4)	

This work was supported in part by funds from the Arts and Sciences Research Fund, the National Institutes of Health and the National Science Foundation.

Note added in proof. Shortly after we submitted this manuscript, an article on learning in *Tenebrio* by Borsellino and his co-workers[7] came to our attention. In contrast to our passive avoidance procedure, the Borsellino study used maze learning; it was satisfying to find that retention over metamorphosis occurred with both types of conditioning.

Rhythmic Patterns in Human Interaction

Now that the importance of rhythmicity in biological behavioural functions has been recognized, the traditional distinctions between psychology and physiology have had to be reappraised. For example, the regular alternation between mania and depression in manic-depressive psychosis suggests the possibility of underlying rhythmic phsyiological mechanisms[1]. Similarly, the temporal structure of social interaction has been investigated and regular patterns have been found[2]. Chapple[3] and others[4] have suggested a loose analogy between these patterns and biological rhythms. Nobody, however, has analysed the temporal structure of interaction with the perspective and statistical techniques of chronobiologists.

Rhythmic patterns of behaviour seemed to emerge in the course of a study of interactions among the patients in sheltered workshops. (These workshops are intended to provide non-competitive employment for physically and mentally handicapped people who do not need to be in hospital permanently, with the aim of helping them to develop the physical and social skills necessary for economic independence.) After the study, one subject was chosen for an intensive chronobiological investigation. So far, frequency analysis has given consistent evidence for high frequency rhythms in interaction; the cycles had periods of approximately 3·0, 6·0 and 12·8 min, which can be regarded as harmonics.

The subject, selected from a group of sixteen, was a woman of 26, mentally retarded and suffering from phenylketonuria (PKU). She had a strong tendency to engage in social behaviour in the absence of any obvious partner or object to which her actions could be related; this tendency I refer to as "interactional auto-action", with the intention of describing only the form of behaviour and not its content. Eighty per cent of the subject's social contact activity was recorded as auto-action and, of the remaining 20 per cent, more than half was initiated by the subject. In other words, the subject herself initiated more than 90 per cent of her recorded social contact time—that is, the time during which she was engaged in auto-action or dyadic interaction. This subject's interaction, especially her auto-action, with its apparently predominant independence resulting in effective behavioural isolation, thus seemed to offer an excellent opportunity to search for an endogenous, free-running rhythm in the absence of external synchronizers.

The behaviour of the subject was recorded by an observer[5] using a remote-recorder which provided a precise record of the temporal patterns of interaction. The data, sampled at a frequency of 100 points/min, were generated as a square wave representing the two conditions of action and inaction (see Fig. 1). The total data sample consisted of numerous "observations"—an observation being the period of time during which the pertinent behaviour of the subject was recorded. The distribution of these sessions fell into two groups (Fig. 2). The 1967 data consisted of fifteen observations of about 15 min, gathered at randomly determined times during the working day; and in 1968, during intensive investigation, twenty-nine 30 min observations were recorded as frequently as possible. The second group allowed for the successive repetition of any existing temporal patterns and for the investigation of longer periodicities. The subject was thus under observation for more than 1,100 min (or 110,000 data points), an adequate sample with which to look for high frequency temporal patterns without any restrictions imposed by infrequent sampling or small sample size.

Continuous Time

Fig. 1. Representation of the raw data. During an observation the subject was observed in her natural setting in a sheltered workshop and, with the aid of a remote interaction chronograph, was continuously recorded either as interacting (action) or not interacting (inaction). This method yielded a continuous square wave (*a*, schematic and not to scale) of the binary on-off condition in terms of a tone on magnetic tape. The data were then converted to digital form (*b*) by an analogue-to-digital converter sampling at the rate of 100 points/min. *b*, A sample of the computer output giving the numerical values of the square wave in hundredths of a minute. Columns 1 and 2 represent action and inaction, respectively. Column 3 gives the cumulative running time from the beginning of the observation. Thus the second action given, which lasted for 0·10 min, started at 21·02 min into the observation and ended at 21·12 min. The unlabelled columns are of no significance.

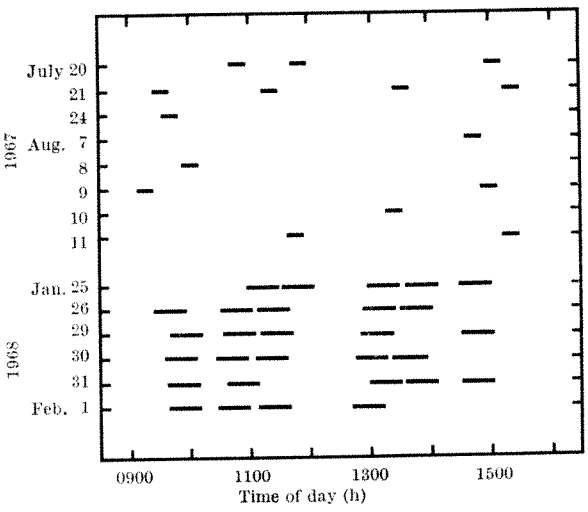

Fig. 2. The distribution of observations. Each observation, represented by a solid bar, constitutes a longitudinal sampling of interactional activity at the rate of 100 points/min. The time of sampling in 1967 was randomly determined; observations were gathered as frequently as possible in 1968.

Two different methods of frequency analysis were used to resolve the hypothesized high frequency signal component in the data. The first was a modification of the periodogram procedure described by Enright[6]. Rather than the root mean square amplitude, the natural logarithm of the smoothed variance values was used as the ordinate value. The smoothing, a simple frequency filtering technique, was achieved with a simple running mean and served to reduce ultra high frequency variation. Because the logarithmic function was used, multiplicative rather than absolute differences were represented on the ordinate scale; this made it possible to compare observations independent of mean levels of activity. The raw data were blocked into equal intervals of 15 s and the duration of interactional activity in each interval was computed. The resultant series of equally spaced sums of "contact duration" was taken as the input data for spectral analysis by the periodogram. The number of switches in the square wave was also computed for each interval and used for a separate periodogram analysis.

In this modified form the periodogram technique scanned all the individual observations for rhythmic components with periods of between 2·0 and 7·5 min; this range represents the spectral window of the analysis. When two sequential observations were separated by only a few minutes of "non-recorded" time, they were joined together to form a record of about 60 min in which the non-recorded time was considered as blank data. In these analyses the window was extended to include periods of up to 15·0 min.

The second method of frequency analysis used fast Fourier transforms as the basis for constructing a power spectrum. Again the raw data were blocked to provide a series of equally spaced sums as input data. The

Table 1. PERIODS OF DOMINANT RHYTHMIC COMPONENTS

Average Period ($\bar{\tau}$):	$\bar{\tau}_5 = 5·9 \pm 0·7$	$\bar{\tau}_{12} = 12·8 \pm 1·1$	2·5 $\bar{\tau}_3 = 3·0 \pm 0·3$ $\bar{\tau}_6 = 6·1 \pm 1·5$	$\bar{\tau}_6 = 6·2 \pm 0·5$	$\bar{\tau}_{12} = 12·9 \pm 1·1$

The results of the periodogram and fast Fourier transform power spectrum (FFT) analysis were computer plotted as a function of period length (in minutes per cycle). The values given represent signal peak positions whenever dominant peaks were present. Many of the joint-periodogram plots showed strong sub-peaks at approximately six minutes. A blank column entry signifies that no signal component was clearly in evidence; asterisks indicate that the particular analysis was not applied to the given observation. Unfortunately the statistical analyses that are available to investigate the significance of these peaks all involve unjustified assumptions, but this problem is common to all chronobiological techniques of spectral analysis. The averages and s.d. given are based on the values of the peak positions in each column.

power spectrum was used to examine only the contact duration data of single observations. The results of this and the periodogram analysis are presented in Table 1.

Table 1 shows that about 70 per cent of the data revealed a temporal periodicity with at least one of the analytical techniques. Considering the complexity of the variables under investigation and the problem of noise interference, this result is very encouraging. More important, however, is the consistency of the periodic components. Based on the individual observations, most peaks in activity correspond to a period of $6·0 \pm 1·0$ or $3·0 \pm 0·3$ min. Similarly, the "joint-periodograms" have yielded values which suggest a rhythmic component with a period of approximately $12·8 \pm 1·1$ min. Because all these results can be considered integral multiples or harmonics of one another, there seems to be a persistent rhythmic component underlying most of the observations. The findings thus suggest that there is a non-random variation in interaction expressed as a rhythmic manifestation of greater and lesser activity. The period of the rhythm seems to be about 3 min or an integral multiple of 3 min. The analyses also indicate a corresponding periodicity in the switching rate between action and inaction in the interactional activity.

Some of the observations, however, showed no periodicity. Because Aschoff[7] has suggested that a truly endogenous periodicity might depend on the functional state of the organism, it is not unreasonable to expect a variation in the manifestation of the periodic component corresponding to the physiological states of the person. In this respect it is interesting that the August 1967 data (observations 9 to 15), which yielded the poorest results in terms of the presence and consistency of periodic components, showed a significantly greater mean level of activity than either July or January ($P = 0·005$). This finding suggests that the mean level of activity may affect the appearance of the rhythmic component. Whether this influence is related to a variation in signal amplitude or the interference of an increased noise level is unknown.

The basis of the rhythm is not known. It may derive from a more general activity rhythm, an underlying cognitive or neural component[8,9], an excitability rhythm corresponding to blood CO_2 and respiration[10,11], or some unknown factor or factors. In any case, however, the similarity of the phenomenon to biological functions suggests that interactional activity may have strong foundations in biology; indeed, the distinction between physiology and behaviour at this level becomes artificial. As such the rhythm may provide the basis for the notion of an "interactional rhythm", an idea which has been used by interactionists with varying precision and definition[3,4]. In the context of rehabilitation, such a manifest rhythm would have a profound impact on a person's social relations, where it might lead to a reduced flexibility in interactional style[12]. An awareness of such a pattern would be of great importance in understanding and effectively dealing with behaviour of this kind.

I thank Dr W. H. Button, jun., Mr B. K. Lubow, Dr V. G. Bruce and Professor F. Halberg for their assistance and encouragement. Book Reviews

SEARCHING FOR PRIORITIES

Biology and the Future of Man

Edited by Philip Handler. Pp. xxiv+936. (Oxford University: New York and London, July 1970.) $12.50; 105*s*.

THE future of man is becoming a fashionable topic these days, even in quite respectable circles. What could be more respectable than the Committee on Science and Public Policy of the US National Academy of Sciences, which has now found it appropriate to give the subject somewhat more than a passing glance—indeed, at a rough estimate, about 400,000 words worth? Not even the most ardent futurologist (always excepting Mr H. Kahn) could really be expected to keep the theme going for that number of pages, and this book does not. The title, in fact, seems almost an afterthought, for the book arose from a decision by the NAS to embark on a series of surveys of the state of the art in particular scientific disciplines, the intention being to discover what the material strengths and weaknesses in basic reasearch were in particular areas. It was the life sciences' turn in 1966, and the bulk of this book is, in effect, a sort of gigantic memorandum, written by a panel of nearly two hundred distinguished biologists; it is obviously the sort of tome which should be found on the shelves of the secretary of any funding agency.

How could such a vast panel function? The usual mode of such operations is to hand each section or chapter out to an expert, to accept what he produces with a few minor editorial amendments, and bulk the whole together with a few well chosen editorial link-words. Not so here. An interesting attempt was made to be more integrated. After each section was prepared, the entire survey committee seems to have met in a [sic] "grueling one week session" with each report "mercilessly exposed to . . . searching, sometimes scathing, criticisms". Such a procedure can certainly work well, but demands a degree of rapport and common purpose among the authors. One is tempted to indiscreet speculation as to just what Drs René Dubos, Theodosius Dobzhansky and Joshua Lederberg could have found to say to Dr Stephen Aldrich, of the Central Intelligence Agency, listed as a "special consultant to the study".

But the method should be judged by its results, and for me, as a finished product, *Biology and the Future of Man* fails. It is obviously deliberately selective, not a textbook but still an attempt to provide an integrated statement of just what the biological revolution of the last decade has been about. It is aimed, presumably, at the intelligent lay grant-giver (and, of course, his public), though it seems improbable that he should ever want to read it all. It runs the gauntlet through molecular and cell biology, biochemistry, developmental biology, physiology, genetics, evolution and ecology to medical practice, environmental health and agriculture, taking in *en route* such fashionable topics as the origin of life and (a full 10 per cent of the entire book) neurobiology and behaviour. Inevitably, the level of the reviews varies, as if the authors are not all talking to the same audience. Bits of the basic biochemistry are on a downright chatty, first year undergraduate level (". . . in 1953, the British biochemist Fred Sanger first demonstrated that the hormone insulin is not a random assembly of amino-acid residues . . ."). Portions of the neurobiology are on the level of a review article in a specialist journal. Terms are introduced without definition or explanation; very complex problems and concepts are tossed around in a manner surely incomprehensible to anybody but the expert. And what expert would be interested in a review that contains neither references nor attributions for work discussed, nor even an index?

These failings would be more excusable if the authors had really addressed themselves either to the theme of the book's title or, less grandiosely but more manageably, perhaps to the question of where research in their own particular area is going. But this, which should surely be the justification of the exercise, eludes them. Some, but not all, do conclude their reviews with an attempt to summarize the chief ongoing research questions, but it is the overview which is so surprisingly lacking: the self-critical approach which should do what the book ostensibly sets out to do, and provide some guidelines for the science policy-maker. If there are conclusions or recommendations, and it would be wrong to say there are none, they are rarely incisive or fundamental enough to ask "what are we doing this research for?". Rather, they assume the Everest-complex. The research is there, and ongoing; should we make the climb by the north or south face?

The overview, and the legitimation for the title of the book, comes in its last 40 pages—an essay, predominantly the work of the editor, which has the book's title as its own. For Handler, at least, there is a clear sense of biological priorities. The most pressing problem (always excluding war) is population and its growth; from excess population spring environmental pollution, overcrowding in the cities, violence, noise and stress. The overriding need is for better contraceptive techniques and governmental population policies. In this area lies the prime research responsibility of the biologist, and in that of improving agriculture. Much further down in the list of biological prospects and problems come those headline catchers of transplants and genetic engineering, a sensible and humane extrapolation of the conventional wisdom. One may not agree with Handler's priorities, but at least he knows what he is after. It might have been better had he written the whole book himself, without all these grand biologists (and the CIA man) to help and advise.

STEVEN P. R. ROSE

CELL BIOLOGY REVIEWS

International Review of Cytology

Edited by G. H. Bourne and J. F. Danielli. Vol. 27. Pp. xviii+407. (Academic: New York and London, February 1970.) 196*s*.

International Review of Cytology

Edited by G. H. Bourne and J. F. Danielli. Vol. 28. Pp. xviii+387. (Academic: New York and London, March 1970.) 196*s*.

Advances in Cell Biology

Edited by David M. Prescott, Lester Goldstein and Edwin McConkey. Vol. 1. Pp. ix+337. (North-Holland: Amsterdam; Appleton-Century-Crofts: New York, 1970.) Hfl. 72; 168*s*; $20.20.

HERE are three books containing articles that cover a wide range of cell biology; two are the latest volumes of a well established series founded twenty years ago, the other is the first-born of a new series. Because the aims of both series are similar from the readers' point of view it is worth comparing how they tackle the problem of presenting cytology to the specialist reader.

International Review of Cytology is simply a collection of articles from all corners of the cytologists' globe and there is no attempt to place articles on related topics together. Not that this in itself is a criticism, but it is a small inconvenience to the reader wanting to use the volumes as a source of information on a particular topic. For instance, in volume 27 there is an article on wound healing in higher plants, while in volume 28 Jacobs (with the exemplary presentation we have come to expect of this author) discusses regeneration of seive tubes in plants. Because the two topics are obviously related why could not the two articles have been juxtaposed, or even combined into a single review of regeneration? Similarly, Taylor's article on the possible mode of evolution of chloroplasts could have been profitably placed alongside the article concerning evolution of mitochondria that appeared in a volume in this series last year. I feel the editors could prevent each volume from becoming just a hodge-podge of reviews by a more foresighted and integrative policy in assembling material for each volume, so turning the series into a more streamlined source of information.

The first volume of the new series *Advances in Cell Biology* has a more uniform content. Five out of its seven chapters deal with various aspects of structure and function of the nucleus. Replication of bacterial and eukaryotic chromosomes is fully discussed by Kuempel and Prescott respectively, while Goldstein and Zetterberg each contribute a chapter on protein metabolism in nuclei. A chapter by Brinkley and Stubblefield on the centromere and centriole contains interesting speculations on how these two bodies work in dividing the chromosomes in cell division. Indeed, a speculative approach in each review chapter is one of the aims of the editors, but only within the framework of a comprehensive survey and synthesis of the literature on the topic under discussion. And with these aims in mind each author has prepared a contribution that should wear well.

On the other hand, the editors of *International Review* allow their authors more latitude in the presentation of their articles. Besides the general workaday review, these volumes contain three other categories of review: the historical, the "self" review and the "hypothetical" review. The history comes from Steward who traces work over the past fifty years on the uptake of salts into plant cells, and from Raven writing about work on the cortex of *Limnea* eggs. The "self" review is by Benazzi-Lentati who describes the studies by herself and her husband into gametogenesis in planarians. This is a useful review because many of their original papers are in Italian, but sadly the editors have neglected to make the author's English more readable. The third type of review is by King who selects certain facts to construct an hypothesis on the process of meitotic crossing-over. There seem to be a number of aspects of meiosis which the hypothesis will not account for, or it contradicts, and for this reason must be judged to be more of an essay in model building. Nevertheless, *International Review* remains an asset on library bookshelves and I imagine *Advances in Cell Biology* will become an asset too. It will be interesting to see how this latter series fares in the future.

PETER BARLOW

IMMUNOLOGY WORKSHOP

Histocompatibility Testing 1970

Edited by Paul I. Terasaki. (Report of an International Workshop held at UCLA and Palm Springs, California, January 20–26, 1970; and the Fourth International Histocompatibility Conference at Los Angeles, January 17–29, 1970.) Pp. 658. (Munksgaard: Copenhagen; Williams and Wilkins: Baltimore, 1970.) 148.50 D.kr.

THIS book is quite different from most of the rash of volumes resulting from meetings and symposia. The usual form is a disconnected assembly of semi-review chapters that were hastily put on tape on the flight to (or from) the meeting; new data are carefully excluded by the unwilling contributor for fear nobody will see them, but contrary to the pleas of the organizers. By contrast this volume is a compendium of all the latest information on the subject. Inevitably it does not describe a coherent story but is arranged in well classified parts: results of the workshop, genetics, serology, histocompatibility, chemistry, maternal-foetal incompatibility, mixed cultures, and methodology.

The reason for the quality of the book is historical; it is the fourth in a series (each being about 200 pages longer than the volume that preceded it), each resulting from a practical workshop and conference where the most up to date information is given and the most advanced ideas discussed. Because almost all those directly involved actually attend or are represented, the coverage is essentially complete.

Important points that emerged from the workshop were: confirmation of recombinants between the two HL-A segregant series, giving a cross-over frequency of the order of 1 per cent; additions to the list of internationally agreed specificity nomenclature; definition of "long" and "short" specificity of antisera (only the short being classifiable as monospecific); inability to attain monospecificity by absorption because of cross-reactivity within each segregant series.

The volume continues the record of an astonishingly rapid advance of the subject, mediated by the workshop meetings. The 1970 book is relatively wide ranging, and because future workshops are likely to be restricted to much smaller aspects of the subject, it is likely to remain a reference volume for some time.

Some basic ideas are still being questioned, for example, division into two segregant series, although this view has the majority in support. A third segregant series is mooted but is not finding much favour generally; to establish such a situation becomes extremely difficult in view of the serological cross-reactivity now demonstrated.

Possible association of HL-A phenotype with disease and of different haplotype patterns in different ethnic groups is discussed, and some differences in cell/tissue distribution could be a new important feature. On the central theme of practical tissue typing the methodology section has several contributions on micro-platelet complement fixation and other methods may also challenge the standard cytotoxicity techniques now in use.

All those involved in the transplantation field in its widest sense will find something important in the book, which makes a companion volume to the proceedings of the transplantation congresses. Outsiders would find the inevitable language problem for which there is no answer in sight.

D. A. L. DAVIES

METABOLISM OF INSECTICIDES

Biochemical Toxicology of Insecticides

Edited by R. D. O'Brien and Izuro Yamamoto (Proceedings of the Fifth US–Japan Cooperative Science Program held in Tokyo, June 1969.) Pp. vii+218. (Academic: New York and London, June 1970.) 79*s*; $8.50.

INTERNATIONAL conferences provide a unique opportunity for specialists in a restricted field to meet and to exchange ideas. Frequently, however, the brief abstracts issued to delegates before the conference provide the only record of the proceedings, to the detriment of those unable to attend. The Tokyo conference of 1969, by its terms of reference, precluded the attendance of experts from many nations, and it is therefore particularly appropriate that seventeen of the contributions have now been published, together with tables, figures, experimental techniques and references.

Most of the contributions possess high scientific merit and all are of interest to the advanced student or research worker. Several articles deal with the metabolism of organophosphorous compounds, carbamate insecticides, rotenone and pyrethroids, particular emphasis being placed on the role of microsomal systems and of the supernatant fraction remaining after the removal of microsomes. Other papers are concerned with the structure, action and metabolism of synergists; one of these, by Kuwatsuka, deals with the way methylene dioxyphenyl synergists are themselves attacked by microsomes.

Several papers, including some I have referred to, discuss such cognate topics as structure-activity relations of insecticides, the causes of selective toxicity and the distribution of insecticides within the tissues of various insects and higher animals. In one otherwise very interesting article on autoradiographic studies of benzene hexachloride isomers, it is unfortunate that the Japanese authors were apparently not able to use their technique to pursue the fate of the δ-isomer (which penetrates insects more rapidly than the toxic γ-isomer), as well as following the distribution of ^{14}C-labelled β and γ-isomers. Yamamoto reviews problems associated with the activity of pyrethroids; Hollingworth provides evidence that O-demethylation is a principal route by which di-methyl organophosphates are degraded. Dahm, in a lucid contribution, suggests that the cleavage of the aryl phosphate bond of parathion (a seemingly hydrolytic process) is a microsomal oxidase reaction, dependent upon NADPH.

It is a pity that the lustrous nature of so much of the scientific work has been somewhat tarnished by non-uniformity of presentation and by rather perfunctory proof-reading. Summaries are sometimes at the beginning of papers and sometimes at the end. In some contributions the tables and figures are conveniently placed in the text and in others they follow the references. Perhaps only the grammatical purist will be troubled by the vacillation of "data" from the singular to the plural (for example, pp. 4, 7, 35, 81), and by constant misuse of the definite article in the Japanese papers. In at least a dozen places, however, grammatical or printing errors lead to a lack of clarity in the scientific exposition (for example, pp. 3, 26, 73, 120, 201), for the reader has no option but to guess the nature of the error. Nevertheless, this book contains much excellent material and is highly recommended to all who have an interest in the metabolism, structure-toxicity relations and physico-chemical characteristics of insecticides.

K. A. Hassall

BODY REGULATOR

The Autonomic Nervous System

An Introduction to Basic and Clinical Concepts. By Otto Appenzeller. Pp. xi + 238. (North-Holland: Amsterdam and London; Elsevier: New York, 1970.) 105*s*.

The autonomic nervous system, sometimes known as the vegetative nervous system, is concerned with homeostatic regulation of bodily functions such as blood pressure and temperature. Books about the system are few and the literature available to students on its dysfunction in disease states is very limited. Lord Brain, in the last personal edition of his classic text in neurology, *Diseases of the Nervous System*, devoted only six of the volume's 879 pages to its disorders. This may suggest to many medical practitioners that autonomic disorders are of little significance, for Brain is studied by almost all post-graduate students of general medicine and by many undergraduates. During the past decade, however, the importance of hypothermia and orthostatic hypotension as complications of many diseases, has been recognized. Thus the current studies of L-dopa in the treatment of Parkinsonism have made neurologists increasingly aware that autonomic dysfunction forms a part of the disease complex of this and many other disorders. Dr Otto Appenzeller has contributed much to the study of autonomic disorders and it is therefore appropriate that he should produce a book on this enormous subject, much of its clinical background being developed from his own wide experience.

This book provides an excellent basis for anatomical reading in the subject but it has concentrated less than might be expected on the physiology of the system. It is a pity, too, that some of the illustrations upon this aspect, such as tracings to indicate blood flow changes, are poor. The anatomical side is strengthened by many observations in comparative anatomy, and it is this aspect of the book which deserves attention, rather than the sections on physiology or clinical problems. To take a specific example, such is the progress in the subject, that the book is already inadequate in its consideration of Parkinson's disease.

I must admit to one further difficulty. I have always looked on the autonomic nervous system as the efferent system of nerves comprising the parasympathetic and sympathetic nervous systems. Dr Appenzeller seems to have a wider view of the meaning of the word "autonomic". This might be correct from the *Oxford English Dictionary* definition of the word, meaning "self regulating", but his usage conflicts with J. N. Langley's original definition at the end of the nineteenth century. He has therefore included chapters on sleep, circadian rhythms and respiration which most neurologists would feel to be inappropriate in this text. Nevertheless the book brings together much useful information which will make it a valuable library source.

R. H. Johnson

FIRST EXPERIENCES

Early Learning in Man and Animal

By W. Sluckin. (Advances in Psychology, Vol. 2.) Pp. 123. (Allen and Unwin: London, August 1970.) 35*s*.

Differences between people are in part related to differences in the experiences they have encountered. Experience affects development in part through a process or group of processes commonly described as learning. Both because a *tabula rasa* may be peculiarly impressionable, and because what is learnt first may affect what is learnt later, learning early in development may be of peculiar importance. But at what stage is the young organism first capable of learning? What are the natures of the learning processes which then occur? Do they occur more readily then than later? How do they affect later development? These are some of the questions which Professor Sluckin explores in this students' guide. For his material he draws on recent studies of non-human species—chicks, puppies and monkeys in particular—as well as man; and he ranges from classical conditioning through imprinting and exposure learning to the development of language and personality. He succeeds in compressing great breadth of knowledge into a slim volume, giving brief introductions to viewpoints as divergent as those of Lorenz and Schneirla, Chomsky and Skinner, Freud and N. E. Miller. His approach is catholic, and the student may sometimes wish for clearer signposts to indicate just where the work of each theoretician is, and is not, fertile.

In a field of study which could too easily become a jungle of ill-defined terms, Sluckin is hardheaded about concepts, though his discussions of imprinting in man and of imitation would have been more incisive had he maintained his own distinctions. The reader will be introduced to a wide range of studies, and the bibliography will show him how to explore further.

R. A. Hinde

TERMITE BIOLOGY

Biology of Termites

Edited by K. Krishna and Francis M. Weesner. Vol. 2. Pp. xiv+643. (Academic: London and New York, May 1970.) 299*s*.

THIS is the second of two volumes of a composite work by some twenty authors. Broadly speaking, volume one was physiological and this volume inclines a little more towards ecology. The first chapter, however, deals with the role of symbiotic organisms in digestion. There is a very full picture of the variety of relation, from the truly symbiotic relation between lower termites and their unique flagellate genera to the less well defined situation in the Termitidae. There is a valuable review of the physiology of the mutualistic relationship, though the, perhaps unavoidable, exclusion of the similar relationship in the cockroach *Cryptocercus* is sometimes frustrating. Mukerji's account of termite embryology is also an excellent and well illustrated treatment of this under-worked field.

Noirot attempts with some success a more exhaustive and reasoned treatment of the nests of termites. Although relatively little is known of the behaviour by which these varied and often very characteristic nests are produced, Noirot's experiments on nest repair suggest some most interesting contrasts within the order. Krishna's chapter on taxonomy and phylogeny introduces the regional section of this book, with chapters on each of the zoogeographic regions and special chapters on Madagascar and on Hawaii and the Oceanic Islands. It was in this section that one might have hoped to find more about the ecology of termites, a subject which was hardly treated in the first volume. Many of these chapters, however, are in the form of a catalogue, genus by genus. Bouillon in his long chapter on the Ethiopian region does not attempt to deal with all the African forms. Instead he tries to give a general picture of the biology of termites in a tropical climate, illustrating, for example, energetics and spatial distribution with selected examples. Harris, dealing with the much smaller Palaearctic fauna, also succeeds in combining a general treatment with a partly ecological account of the life of termites in what is not generally a very favourable zone. The remaining chapters make heavy reading, moving at their worst from genus to genus with the times of mating flights and nest situation of each. The author of the final chapter summarizes it when he says "the principles of termite control have undergone few significant changes in several decades". He also advises that in sounding timber for termite damage the hammer "must be used carefully or not at all in the examination of finished wood".

The two volume work will become an indispensable reference work, but it is in some ways disappointing because of the unenterprising way it has been conceived. Nobody would suggest that species-by-species accounts are not valuable, but they can be very dull. Perhaps the reader who wants to know all about a particular species would be well enough served by the good index.

J. H. SUDD

SEX IN INSECTS

The Physiology of Insect Reproduction

By Frantz Engelmann. (International Series of Monographs in Pure and Applied Biology. Division: Zoology, Vol. 44.) Pp. ix+307. (Pergamon: Oxford and New York, July 1970.) 140*s*; $18.75.

THERE is a gigantic literature concerning the reproduction of insects. In this book F. Engelmann provides an exhaustive survey of physiological aspects ranging from sex determination and differentiation, the processes of mating and insemination, factors regulating fecundity, and the role of hormones in male and female, to the control of oviposition. All parts are covered comprehensively with almost every statement documented and with no words wasted on unresolvable hypotheses. The result is not a book for light and easy reading, but is one that will prove invaluable to those who really wish to learn what is known about a given topic and are prepared to read slowly. One naturally turns to those topics which are being most actively studied at the present time—pheromones in mating, or hormones and egg maturation—to find these complex subjects admirably covered.

It has long been one of the dogmas of insect physiology that hormones are not involved in sex differentiation. This belief was refuted a few years ago by Naisse who showed that in the glow-worm *Lampyris* the apical cells of the testis produce a masculinizing hormone, so that, whereas the ovaries develop normally in the neutral environment of the female, they are converted into testes if transplanted to the male at the appropriate time in development. As Engelmann points out, it may be that this phenomenon is more common in insects than is believed, and that in mosquitoes of the subgenus *Ochlerotatus*, which suffer feminization when the larvae are exposed to unduly warm conditions, it could be that an androgenic hormone in the male is inactivated at high temperature.

Besides the standard processes of insect reproduction, the many strange anomalies are also described: parthenogenesis, which is very frequent, heterogony or the alternation of sexual and parthenogenetic generations, viviparity in its many forms, functional hermaphroditism as it occurs in the notorious cottony cushion scale *Icerya*, traumatic insemination through the body wall as in some of the cimicids, and paedogenesis, that strange form of parthenogenesis where, sometimes for many generations (as in the fungus gnat *Miastor*), the oocytes in the larval ovaries grow into young larvae which consume the contents of their mother larva and then break out through the skin. The final section deals briefly with insect societies and the caste system in which reproduction is limited to the queen and her consort, who may produce many millions of offspring during their term of office.

The book has a glossary, a reference list with nearly 2,000 titles, and a subject index with the names of the insects discussed.

V. B. WIGGLESWORTH

FISH CULTURE METHODS

Traité de Pisciculture

By Marcel Huet, with the assistance of J. A. Timmermans. Fourth edition. Pp. xxiv+718. (Editions Ch. de Wyngaert: Brussels, 1970.) $19.00.

THE fourth edition of Professor Huet's treatise on fish culture has been revised, and also expanded to twice the length of the previous edition, and now appears as a substantial clothbound volume.

The original chapters on the construction and layout, the natural history, and the natural productivity of fishponds are little changed; but the account of the management and improvements of ponds has been enlarged to include more methods of weed control, and of influencing the chemical and physical factors concerned with increasing crops of fish.

The account of salmoniculture is unchanged in length, but that on carp culture has been much expanded and now includes not only the common carp, still the mainstay of European fish farming, but also brief accounts of other European and acclimatized Asiatic carps, and of the increasing and profitable culture of small cyprinids as live-bait fish for sale to anglers.

New chapters deal with the culture of percomorphid fishes (pike, pikeperch, walleye, black bass, tilapias), and silurids (the European *Wels*, catfish in America—a fast-growing industry—and *Clarias*, or mudfish, in the Eastern tropics). Under the heading of "Special Fish Cultures", Huet describes the culture of the eel in Europe and Japan, and fish culture in ricefields and brackish water. A new chapter gives a brief survey of fish culture by regions; and there are new chapters also on the diseases and enemies of fish, on artificial foods, which are rapidly gaining in importance, and on the harvesting, transport, and care of live fish. Methods of culture of 124 species of fish are given, of which cyprinids comprise twenty-eight species and salmonids twenty-two species.

More attention is given to the culture of fish to restock waters depopulated by engineering works, by pollution, or by excessive fishing. Detailed accounts are given of the culture of pike, coregonids, shads, grayling, and sturgeons.

An attractive feature of all editions has always been the splendid illustrations, which have been increased to 503 in this edition. But I must again regret the lack of an index, more than ever desirable in this much enlarged volume.

C. F. HICKLING

ROCK FABRICS

An Introduction to the Study of Fabrics of Geological Bodies

By Bruno Sander. Translated by F. C. Phillips and G. Windsor. Pp. xvii+641. (Pergamon: Oxford, London and New York, June 1970.) 240*s*; $32.

ALL geologists with more than a superficial knowledge of structural petrology will be aware of the fundamental contributions of the late Professor Sander to the development of this subject. For most British and American readers acquaintance with his ideas has been uneven and derived mostly at second hand, because his original papers and books were written in a difficult German style. This imposing volume is a translation of two textbooks published in the period 1948 to 1950 that set down Sander's views on rock fabrics based largely on his own work. They were intended to illustrate the scope and methods of fabric studies to those intending to apply them to their own problems, and to introduce them to non-geologists who might be able to adapt them to their own problems. The approach led through a highly philosophical introduction to a very practical treatment that included full accounts of field and laboratory techniques, as well as numerous fully worked examples. This translation was made in response to many requests for publication of an earlier version made by one of the translators (F. C. P.), and was undertaken at the express wish of Professor Sander.

The book is in two parts; the first introduces the theory and deals with large scale features down to the hand specimen, while the second is concerned with laboratory investigations and the interpretation of grain fabrics. It represents a very valuable addition to the somewhat sparse literature on this subject in English; the second part, in particular, presents a much more detailed account of the techniques and analysis of grain fabrics than has hitherto been available. In the interests of clarity some parts have been translated rather freely, but no attempt has been made to bring the work up to date or to make substantial changes to the original rather ponderous philosophical style. An obvious weakness lies in the age of the original text, but the translators were clearly aware of this and have added a useful bibliography of supplementary references up to 1967. The work is handsomely bound and many of the diagrams have been specially redrawn.

The translators are to be congratulated on the completion of an exceptionally difficult task, for this is an excellent production which will be a standard reference for research workers. Although the book will undoubtedly appeal to those who are already familiar with the subject, it cannot be so recommended to beginners. The translators would earn further acclaim if they could now see their way to producing a condensed account based on this material to meet their needs.

I. D. MUIR

RADIATION MEASUREMENT

Applied Radiation Protection and Control

By J. J. Fitzgerald. Vol. 1: Pp. xii+1–540. 250*s*; $30. Vol. 2: Pp. 541–1018. 175*s*; $21. (Gordon and Breach: New York and London, June 1970.)

RADIATION protection embraces many disciplines and, in consequence, it must be difficult for one man to write what the preface to this book calls a "Handbook of Radiation Protection and Control Data". It is certainly not possible for one reviewer to give adequate critical treatment to all twelve chapters (in these volumes), but a study of those which fall within my special competence is not encouraging as far as the others are concerned.

Many of the illustrations are taken from textbooks of the 1950s, US Atomic Energy Commission laboratory reports of the 1950s, or are derived from measurements made by the author in the 1950s. Much detailed information relates to apparatus which was available in the United States eight or more years ago, and, in general, the book is rather dated. Reference is made to publications of the US National Committee on Radiation Protection up to 1966 (although little use is made of them in the text), but international organizations fare much worse. What are stated to be the structures of the International Commission on Radiological Protection (ICRP) and International Commission on Radiological Units and Measurements (ICRU) "at the present time" are, in fact, many years out of date. There is no reference to any ICRP publication later than 1959, and although ICRU reports up to 1963 are cited their recommendations are not incorporated in the text, because the author still speaks of "exposure dose", gives a long outmoded definition of the roentgen, and nowhere even mentions "quality factor" or "dose equivalent". A book with these deficiencies which also calls liquid scintillation counting "a rather recent innovation" and has no reference to the rapidly developing subject of thermoluminescent dosimetry later than 1960 cannot be recommended for use in the 1970s.

J. R. GREENING

FUNDAMENTALS OF PHYSICS

Fundamental Principles of Modern Theoretical Physics

By R. H. Furth. (International Series of Monographs in Natural Philosophy, Vol. 24.) Pp. xv+351. (Pergamon: Oxford, London and New York, April 1970.) 90*s*; $12.

THE principal object of this book is to give an introductory development of quantum theory, relativity (special and general) and statistical mechanics. It is not a specialist textbook, in the strict sense of the word, but a presentation of the fundamentals with emphasis on ideas rather than rigour. As one who thinks that nowadays practical applications tend to overshadow the basic ideas of a subject, I applaud the author's approach. Of course applications are vitally important and are not entirely neglected in this book.

Dr Furth has properly concentrated on the more standard topics but, in an introductory text of this kind,

there should be more discussion of more recent or more advanced areas in order to whet the reader's appetite. One need only give a taste. Often a single word would do. The author has tried to do this as, for example, in the section on the Dirac equation (itself a formalistic titbit) where the exotic words "spinor calculus" appear. More of this is needed.

There would be no sense in discussing omissions in what is an admittedly selective text, but I think it regrettable that nowhere do the words group theory occur. The ideas can hardly be classed as recent or difficult and a few words only would have served to link vectors, tensors, spinors and angular momentum in a significant way and could have provided a tempting foretaste of symmetries and the classification of elementary particles.

Nevertheless within the limits set by the author this is a really excellent text and can be highly recommended either for teaching or self study. The style is lucid and the various sections are nicely arranged.

Finally, one error of detail caught my eye: the "four" in the four dimensional Dirac matrices is not the same "four" that occurs in the four dimensions of space-time, as the author seems to imply on p. 213.

J. S. DOWKER

SATELLITE PROBLEMS

Principles of Celestial Mechanics

By Philip M. Fitzpatrick. Pp. xvii+405. (Academic: New York and London, June 1970.) 119*s*.

THE title of this book does not adequately indicate its contents: although Professor Fitzpatrick certainly expounds the principles of celestial mechanics, his principal concern is with the problems of artificial satellites and the treatment is directed to that end. The first six chapters are chiefly occupied with the fundamentals, two-body orbits, expansions in elliptic motion and systems of coordinates. Chapters seven to eleven cover Lagrange's planetary equations, Hamiltonian functions and Hamilton-Jacobi theory. In chapter twelve gravitational potential is discussed, and in chapter thirteen the drag and gravitational perturbations of Earth-satellite orbits. The final chapter is really quite separate, being an account of the rotational motion of an artificial satellite.

The early sections of the book provide a sound introduction to the various concepts and problems of celestial mechanics, and the bias towards space will be welcomed by the majority of students of the subject who will make their careers in the space industry rather than in pure astronomy. Occasionally the mathematical treatment is a little laboured, or even clumsy, but again many students may like an intelligible step-by-step approach better than smart but mystifying tricks. The part of chapter twelve on the Earth and its gravity field is not entirely satisfactory: there are several misleading remarks, particularly on page 287, where it is implied that satellite orbital theory has not been developed for high-order harmonics. In fact there have been many generalized treatments covering all harmonics such as those of Groves (1960) and Kaula (1961), and also explicit formulae for the variations in orbital elements, such as those of Merson (1963). Chapter thirteen also has faults: the lengthy discussion of atmospheric drag effects, although correct as far as it goes, remains entangled in academic complications instead of exposing the practical problems. But the final chapter is particularly thorough and is a valuable addition to the material.

All in all, this is a competent and useful university textbook. Although it has defects, they are outweighed by the virtues of its clear and straightforward exposition.

D. G. KING-HELE

Short Notices

The Upper Thames.

By J. R. L. Anderson. (T Regions of Britain.) Pp. 301+40 plates. (Eyre a Spottiswoode: London, July 1970.) 75*s*.

FOR a river which has been associated with hum settlements for as long as a quarter of a million ye or more, it seems a little strange that the exact origin the River Thames is still disputed. The author of t readable and informative book seems, however, to fav a spot in a clump of trees at Trewsbury Mead, n Cirencester, and so does the Thames Conservancy, for has appropriately marked the place with a statue of Father Thames which once adorned the Crystal Pal in London. From Trewsbury Mead, the river wande with a few unexpected twists, to London and the s Mr Anderson, however, has restricted his book to Thames's upper tracts, well westward of London, ir region bounded by the hill country of its source to west, Banbury in the north, Thame in the east, a Newbury and Kennet in the south. The emphasis is the history of human settlements in this remarka unified region, but the author also describes the charac of today's towns and villages. The book is supplied w a splendid set of photographs, several maps, a gazett and an itinerary for a river cruise. It is a delight read.

Collins Guide to Tree Planting and Cultivation.

H. L. Edlin. Pp. 349+59 illustrations. (Collins: Lond September 1970.) 42*s*.

IF you have a drooping oak which looks near to colla it may be time to call in the tree surgeon to bolster it using his armoury of antiseptic creosote, cables, s and hatchets. If, however, there is a well establis stump to be removed he may have to bring his explosi and stump gobbler. Although H. L. Edlin advises a teurs against attempting any but the simplest surg he explains the techniques in this thoroughgoing gu But this is not just a book for amateurs; it is pac with every sort of information for tree planters, whet operating on a tiny scale in the back garden, or o large scale in the forest. Half the book is taken up w a catalogue telling which trees should be planted wh and when, and how they should be tended thereaf If this advice is heeded, many trees might be saved fr certain death as a result of being planted in unsuit conditions.

Geological Highlights of the West Country: A Nat

Conservancy Handbook. By W. A. Macfadyen, v contributions by A. W. G. Kingsbury. Pp. (Butterworth: London, July 1970.) 60*s*.

MOTORISTS with a bent towards geology who are head for the south-western counties of Britain may like tuck this new handbook into a handy pocket in t motor-cars. By planning their route to take in som more interesting geological features to be found in Son set, Gloucester, Dorset, Devon and Cornwall, they may find they have missed the traffic jams. This guide descr ninety interesting sites, with their special inter indicated, and several caves, some noted for their asso tion with Palaeolithic man. Exact locations are gi and Dr Macfadyen has also included maps of each cou with the described sites marked on them so as make the planning of a geological itinerary all the ea There are also plenty of helpful map sections stratigraphic successions, but the six photographs poor.

Correspondence

Chinese Restaurant Syndrome

SIR,—There is a major criticism that can be raised against the conclusion presented by Morselli and Garattini[1] that there is no connexion between the ingestion of monosodium glutamate and the Chinese restaurant syndrome. This is that they did not use susceptible subjects. From the very first reports of this condition it was apparent that only a relatively small proportion of normal individuals was susceptible[2], the proportion being higher among women than among men[3] (most of the subjects in the experiments reported by Morselli and Garattini were men). Obviously a study of non-susceptible subjects only will not reveal significant reactions.

My own interest in the Chinese restaurant syndrome arises from my suffering from this condition for at least twelve years before the original description of it by Ho Man-Kwok[4] in 1968. The onset of my recognition of the symptoms occurred when I moved from England to Boston and started to eat in the many excellent Chinese restaurants in that city. Like others[3] I was able to prepare a list of "safe" and "to be avoided" Chinese restaurants.

From my personal experiments (unfortunately with only one subject) I can assure the authors that a susceptible subject is capable of recognizing whether monosodium glutamate has been ingested or not: to some extent the amount ingested can also be judged from the severity of the symptoms.

Yours faithfully,

JEAN HIMMS-HAGEN

Department of Biochemistry,
University of Ottawa,
Ottawa 2, Canada.

Milk Secretion

SIR,—Wooding, Peaker and Linzell[1] seem to portray the knowledge of milk secretion as involving little enlightenment and continuing controversy. In my opinion progress in this field has been impressive and substantial agreement regarding the process is emerging. The two basic milk secretion mechanisms discovered by Bargmann and Knoop[2], one involving expulsion of fat globules by envelopment in plasma membrane and the other emptying of Golgi vesicles containing milk proteins through the plasma membrane, are widely accepted as fact. Wooding *et al.*[1] (among others) have reported crescents of cytoplasmic material attached to some (1 to 5 per cent) secreted milk fat globules. They combine this observation with their detection of cytoplasmic fragments (concentration ?) in milk as evidence supporting and reviving the theory of apocrine secretion; that is, secretion by cell decapitation with loss of cytoplasm. The unpublished findings of at least three additional groups confirm their observations regarding crescents and all will agree that average milk contains minor amounts of cellular debris.

It seems important to ask how quantitatively significant are these apocrine manifestations. In the case of the cytoplasmic crescents, it can be assumed that average bovine or caprine milk contains about 4 per cent by volume of fat globules. Using the figure by Wooding *et al.* of 1 to 5 per cent of globules with crescents attached, and assigning an average volume of one-fourth globule volume to the crescents, this aspect of the apocrine mechanism concerns 0·01 to 0·05 per cent of the milk volume. There appears to be little loss of crucial cell machinery into milk such as nuclei, pointed out by Wooding *et al.*[1], or mitochondria[3]. In fact the very low levels of phospholipid in milk (0·02–0·05 per cent) indicate that relatively little cytoplasmic membrane material of any kind is secreted.

Yours faithfully,

STUART PATTON

Division of Food Science and Industry,
The Pennsylvania State University,
University Park, Pennsylvania 16802.

A Definition of Intelligence

SIR,—In the course of work on cybernetic machines we became increasingly concerned with the problem of intelligence in machines and intelligence in man. An adequate definition of intelligence could not be found in literature and a new one relevant to this problem seemed to be necessary. After due consideration the following definition was formulated:

> "Intelligence is that faculty, of mind, by which order is perceived in a situation previously considered disordered."

This definition resolves the potential conflict between so-called intelligent machinery and man since it ascribes, by definition, intelligence only to organisms which have a larger set than a machine can have. Thus machines may have intelligent-like performance but cannot be intelligent because the machine's instruction set is a proper subset of man's instruction set.

Yours faithfully,

H. A. FATMI
R. W. YOUNG

Chelsea College,
University of London,
London SW3.

Phenolase Inhibitors

SIR,—J. R. L. Walker reported isolation of an unknown phenolase inhibitor from cultures of *Penicillium expansum* (*Nature*, **227**, 298; 1970). We have found that penicillamine (a degradation product of penicillin) is a potent inhibitor of both mammalian and plant phenolase[1]. It is likely that small amounts of penicillamine accumulating in the culture medium cause the inhibition of *o*-diphenol oxidase.

Yours faithfully,

K. PRABHAKARAN

Obituary

Academician M. M. Shemyakin

MIKHAIL MIKHAILOVICH SHEMYAKIN, who died on June 26, was one of the leading organic chemists and biochemists in the Soviet Union.

He was born in 1908 in Moscow, and was educated at Moscow State University, where he graduated in 1930. In the years that followed, he was attached to a number of research institutes and establishments: the Institute of Organic Semi-products and Dyes (1930–35), the Moscow Institute of Precision Chemical Technology (1935–45), the All-Union Institute of Experimental Medicine (1937–59), the Moscow Textile Institute (1945–47) and also the Institute of Biological and Medical Chemistry of the Academy of Medical Sciences of the USSR. Since 1964 he had held the post of Academic Secretary of the Department of Biochemistry, Biophysics and Chemistry of Physiologically Active Compounds of the Academy of Sciences of the USSR; since 1960 he had been Director of the Institute for the Chemistry of Natural Compounds of the Academy of Sciences of the USSR.

Shemyakin's research covered the chemistry of natural compounds and molecular biology. He made outstanding contributions to the study of the structure and function of the principal biopolymers and bioregulators, and carried out fundamental research into the problems of proteins and peptides, biological membranes, antibiotics and vitamins. He was author or co-author of a number of definitive works in these fields, including *The Chemistry of Antibiotics* (1953), *Oxidizing-Hydrolytic Transformations of Organic Compounds* (1957) and *Stereochemistry and the Mechanism of the Witting Reaction* (1963).

He played a considerable part in the development of biochemistry and organic chemistry throughout the Soviet Union, taking an active part in the organization of new research centres and institutes and in stimulating the work of biologists, chemists and physicists engaged on the solution of many currently pressing problems of Soviet science and the Soviet economy. For his services to the economic progress of his country, he had been awarded a number of Soviet orders and medals, and had been made a Hero of Socialist Labour. He also devoted much attention to the fostering of international links in science and was one of the Soviet representatives on the Scientific Advisory Panel of the Ciba Foundation. Shortly before his death, he had been Honorary President and Director of the International Symposium on the Chemistry of Natural Compounds in Riga.

Academician A. V. Shubnikov

ALEKSEI VASIL'EVICH SHUBNIKOV, the leading Russian crystallographer, died on April 27, in his eighty-fourth year.

Shubnikov was born in Moscow and began his research in 1910, while still a student at Moscow University. During the following sixty years, he carried out wide-ranging investigations of the theory and practice of crystallography. His research into symmetry led to the formulati of the concept of generalized symmetry (antisymmetr; He made a considerable contribution to the developme of the theory of piezoelectricity, and was responsible the discovery and application of a number of pie electric materials. His outstanding work on the growi and processing of crystals made him a pioneer of t synthetic crystals industry of the Soviet Union.

In addition to his research work, Shubnikov was sponsible for the initial organization of the Institu of Crystallography of the Academy of Sciences of t USSR, of which he was director for more than twen years. He founded the Department of Crystal Phys of Moscow University, and was founder and first editor-chief of the journal *Kristallografiya*. He was the auth of a number of standard works on crystallograp including original monographs and textbooks.

For his discoveries in crystallography and his servi to Soviet science and industry, Shubnikov was award a number of prizes and honours, including two St Prizes, the Order of Lenin (twice), the Order of the R Banner (twice) and the title of Hero of Socialist Labo

Dr M. M. Gerasimov

MIKHAIL M. GERASIMOV, one of the most outstandi figures in modern Soviet archaeology, died on July after a prolonged, unspecified illness.

Gerasimov, who was born in Leningrad in 1907, co bined his studies as an anthropologist and archaeolog with a considerable talent as an artist and sculpt In 1927, following his discovery of the upper Palaeolitl settlement of Mal'ta (80 km from Irkutsk), he beca interested in the possibility of the reconstruction of t soft tissues of the face, using the principles of anthropolo and the techniques of sculpture.

In 1927, he began work on a series of "portraits" various anthropological types and historical figures, t latter including Timur (Tamerlane), Andrei Bogolyubsl Yaroslav the Wise, Admiral Ushakov, Ivan the Terril and Friedrich Schiller. His Palaeolithic and Neolitl reconstructions covered the main archaeological sites the world; special emphasis was placed, however, on t Mal'ta settlement and also Trepole (Ukraine).

His work established plastic reconstruction as a rec nized part of Soviet archaeological practice, and a spec laboratory for this was founded under his directorsh a post which he held to the end of his life.

His work has also found an application in foren science.

His principal publications include *The Principles Facial Reconstruction on the Basis of Skull Formati* (1949) (for which he was awarded a Stalin Prize in 195 *Facial Reconstruction on the Basis of Skull Formati Modern and Fossil Man* (1955) and *The Mal'ta Pala lithic Settlement and its Place among the Palaeolithic Rel of Siberia* (1961).

Announcements

University News

George B. Field has been appointed chairman of the Astronomy Department at the **University of California** (Berkeley), in succession to **Ivan R. King. Dr Harold M. Agnew** has assumed direction of the **Los Alamos Scientific Laboratory**, New Mexico, operated by the University of California for the US Atomic Energy Commission. He succeeded **Norris E. Bradbury**, w has retired.

Michael B. McElroy, formerly at Kitt Peak Natio Observatory, has become Abbott Lawrence Ro professor of atmospheric science at **Harvard Universi Dr Neal Balanoff** has been appointed professor instructional development and director of a ne

established Office for Instructional Development at the **Harvard School of Public Health.**

Dr E. A. Faulkner has been appointed to the professorship of solid state electronics recently established in the Department of Physics, **University of Reading.**

Professor Walter E. Meyerhof has been appointed chairman of the Physics Department at **Stanford University,** in succession to Professor **Arthur Schawlow.**

Dr R. W. Coles, formerly at the Claremont Colleges, California, has been appointed director of the **Washington University Tyson Research Center,** near Eureka, Missouri.

Appointments

Dr DeWitt Stetten, jun., dean of the Rutgers University Medical School, has been appointed director of the **National Institute of General Medical Sciences,** US Public Health Service.

Sir Roger S. Falk has been reappointed chairman and **Mr J. G. Jenkins** deputy chairman of the **Central Council for Agricultural and Horticultural Co-operation. Alderman F. T. Hussey, Mr A. Norton, Mr H. R. Kemp** and the **Hon. J. Addington** have been appointed independent members of the council. The following members have been appointed from nominations by the farmers' unions and central cooperative bodies: *England,* **Mr R. Butler, Mr G. D. Robinson;** *Scotland,* **Mr W. Peat, Mr Goodfellow;** *Wales,* **Mr D. L. Carey Evans, Alderman T. Jones;** *Northern Ireland,* **Mr F. M. B. Loane, Mr W. J. Crawford.**

Professor Norton Ginsburg, professor of geography at the University of Chicago, has been elected president of the **Association of American Geographers.**

Miscellaneous

Dr W. M. Hutchison, University of Strathclyde, has been awarded the **Robert Koch prize and medal for 1970** for his work on toxoplasmosis infection.

Dr Marvin Legator, chief of the Cell Biology Branch, US Food and Drug Administration, has received the Key lecture award of the **American Genetics Association** for his contributions to the implementation of genetics for human welfare.

Professor J. J. Weiss has been awarded the Marie Curie medal of **l'Institut du Radium,** Paris, in recognition of his contributions to radiation chemistry and radiobiology, and to mark his retirement from the chair of radiation chemistry, in the University of Newcastle upon Tyne.

Dr Irvine H. Page, director of the Research Division of Cleveland Clinic Foundation, and **Sir George Pickering,** master of Pembroke College, Oxford, share the **1971 Stouffer prize** for their investigations and leadership in the field of heart research.

Sir Alexander Haddow, former director of the Chester Beatty Research Institute, has been awarded the **1970 Sidney Farber Medical Research award** by the Children's Cancer Research Foundation, Boston, for his contributions to the development and support of medical care and research.

The **International Union of Food Science and Technology** was formally inaugurated on August 14 in Washington DC. The Union is intended to foster international cooperation and to support progress in research and technology in food science. Membership is open to all nations on the basis of one representative body from each nation. Further information can be obtained from the Secretary General, Professor Erik von Sydow, Swedish Institute for Food Preservation Research, Kallebäck, Göteborg S, Sweden.

Applications are invited by the Banting and Best Department of Medical Research, University of Toronto, for the **C. H. Best Foundation postdoctoral fellowship** which is part of a new research programme placing special emphasis on hormones and other agents that regulate body chemistry. The fellowship is for two years and carries a basic stipend of $8,000 a year. Further information can be obtained from the Department of Information, University of Toronto, Toronto 5, Ontario, Canada.

Lalor Foundation postdoctoral research awards are available to investigators concerned with mammalian reproductive physiology—in particular with uterine phenomena as they may relate to early gestation, the dysgenic aspects of such phenomena, and better and safer means of prophylactic termination of pregnancy. The awards are open to workers of any nationality under the age of 41, and can be used for work at the candidate's own institution or elsewhere for any period up to one year. Further information can be obtained from the Lalor Foundation, 4400 Lancaster Pike, Wilmington, Delaware 19805, USA. The final date for receipt of applications for 1971 awards is January 15, 1971.

ERRATUM. In the article "Single Hit Aetiology of Human Minor Congenital Malformations unassociated with Major Malformations" by E. B. Hook and J. J. Perry (*Nature,* **227,** 847; 1970), the second and third sentences of the footnote to Table 3 should read: If unilateral manifestation is independent, then the expected bilateral incidence is the product of the probability of occurrence on either side. This cannot be calculated from the data in their present form, but can be shown, for these data, to be less than the square of the total observed unilateral incidence which is given in this column.

ERRATUM. In the article "The Classical Charged Photon", by P. Dolan (*Nature,* **227,** 825; 1970), the following changes should be made: the fourth sentence of paragraph 1 should read "In Bonnor's solution L^i, the propagation vector of the electromagnetic field, is always parallel to J^i . . ."; the second sentence of paragraph 2 should read "(I write $\tilde{\pi} = -N_{i;k}\bar{M}^i L^k$ to avoid confusion with the transcendental number π.)"; in equations 6 all π except those with factor 2 in front of them should read $\tilde{\pi}$; φ_t should be φ_1 and a should read α.

International Meetings

October 6–7, **Agricultural and Allied Industrial Tractors,** London (Institution of Mechanical Engineers, 1 Birdcage Walk, London SW1).

October 6–9, **Corrosion and its Prevention by Non-metallic Composite Materials,** Cardiff and Avonmouth (Peter Oldham, Plastics Design and Engineering, Culcheth, near Manchester).

October 13–14, **Environmental Improvement—Agriculture's Challenge in the Seventies,** Arlington, Virginia (Carol L. Rogers, Office of Information, US National Academy of Science, 2101 Constitution Avenue NW, Washington DC 20418, USA).

October 13–16, **Industrial Reciprocating and Rotary Compressors: Design and Operational Problems,** London (Institution of Mechanical Engineers, 1 Birdcage Walk, London SW1).

October 14–16, **Earth Station Technology,** London (Mrs Ann Cook, Manager, Conference Department, Institution of Electrical Engineers, Savoy Place, London WC2R OBL).

October 20, **Acoustics as a Diagnostic Tool.** London (Institution of Mechanical Engineers, 1 Birdcage Walk, London SW1).

British Diary

Monday, October 5

Scientific Film Evening (6.30 p.m.) Society of Chemical Industry, at Shell Centre Theatre, Shell Centre, London SE1.

Tuesday, October 6

Agricultural and Allied Industrial Tractors (two-day symposium) Institution of Mechanical Engineers, Automobile Division, at 1 Birdcage Walk, London SW1.

How We Learn About the Ultimate Nature of Matter (5.30 p.m.) Professor C. C. Butler, FRS, Royal Institution at 21 Albemarle Street, London, W1. (Lecture for Sixth Form pupils from Schools in London and the Home Counties. To be repeated on October 7, 13 and 14.)

Just What are Plastics ? (7 p.m.) Mr A. G. Jones, Society for Analytical Chemistry, at the Eden Arms Hotel, Rushyford, Ferryhill, Co. Durham.

Manufacture of Wallpaper (7.30 p.m.) Mr A. O. Sutherland, Oil and Colour Chemists' Association, jointly with the Society of Dyers and Colourists, at the Griffin Hotel, Boar Lane, Leeds.

Preventing Wind-Induced Oscillations of Structures of Circular Section (5.30 p.m.) Mr D. E. Walshe and Mr L. R. Wootton, Institution of Civil Engineers, at Great George Street, London SW1.

Wednesday, October 7

Colour Education and Training (2 p.m. seminar) Colour Group (Great Britain), in the Mechanical Engineering Department, Imperial College, Exhibition Road, London SW7.

The Development of Flame Spectrophotometric Detectors for Gas-chromatography (7 p.m.) Professor R. Hermann, Society for Analytical Chemistry, in the Scientific Societies Lecture Theatre, 23 Savile Row, London W1.

Urban Motorway Planning and Elevated Structures (6.15 p.m.) Mr R. L. Wilson and Mr P. A. Brown, Institution of Civil Engineers, at Great George Street, London SW1.

Thursday, October 8

Optical Methods in Electrochemistry (6.30 p.m.) Mr R. Parsons, Mr J. Albery and Mr M. Stedman, Society for Analytical Chemistry, at the School of Chemistry, The University, Bristol.

Practical Applications of an HF Plasma Torch to Emission Spectrography (6.30 p.m.) Mr S. Greenfield and Mr P. B. Smith, Society for Analytical Chemistry, Midland Section, in the Large Lecture Theatre, Henry Wiggin and Co., Ltd, Holmer Road, Hereford.

The South East Regional Plan (4 p.m. informal discussion) Institution of Civil Engineers, Transportation Engineering Group; and the Regional Studies Association, at Great George Street, London SW1.

Friday, October 9

Industrial Espionage (6.30 p.m.) Major R. B. Matthews, Oil and Colour Chemists' Association, at the Manchester Literary and Philosophical Society, 36 George Street, Manchester 1.

Mammalian Responses to Cold (2 p.m. symposium) Society for Low Temperature Biology, at the British Institute of Radiology, Welbeck Street, London W1.

The Development of Flame Spectrophotometric Detectors for Gas-Chromatography (6.30 p.m.) Professor R. Hermannn, Society for Analytical Chemistry, in the Chemistry Tower, The University, Salford.

Monday, October 12

Jacking of Railway Bridge Abutments (5.30 p.m. informal discussion) Institution of Civil Engineers, at Great George Street, London SW1.

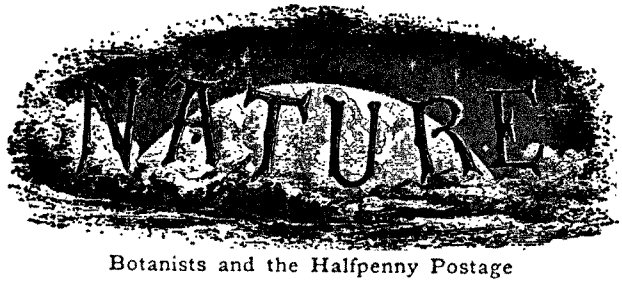
Turn Up for the Book

NOTHING could more vividly demonstrate the futility of sciency policy in the United States than the way in which, at the end of the Congressional season, it should turn out that the Mansfield amendment to the Military Appropriations bill should have been thrown away. It now seems that the full rigours of the Mansfield amendment, with its insistence that research supported out of military funds should have a "direct and apparent relationship" to military operations, will not in future be applied, but enough of the financial year has gone for damage to have been done. After all, the watering down of the Mansfield language has not been accompanied by the appropriation of sums of money to allow abandoned projects to be restarted and, even if Congress had thought of setting aside the money, the chances are that the Administration would have declined to spend it. To be sure, next year there may be more freedom for the Pentagon to support basic research. Certainly, other agencies will feel less threatened than in the past year by the presence of the Mansfield amendment on the books. In retrospect, then, there is a possibility that the whole episode will be regarded as a temporary setback—a storm that came and went. That would be a great misfortune.

The lasting value of the fuss about the Mansfield amendment is that it has demonstrated as clearly as anybody could wish the anomalies in the present system for supporting research with public funds in the United States. Senator Mansfield was, of course, right to protest at the way in which defence money has in the past several years been spent on the support of basic research. Who at this stage will carry a torch for Project Themis, the Pentagon's ill-judged attempt to set up in competition with the National Science Foundation as a sponsor of excellence in American universities? And who is happy at the way in which a great deal of the encouragement of basic research in the fifties and sixties was dependent on the willingness of the military services to listen less critically to appeals for help from academics than the regular grant-giving agencies, particularly the National Science Foundation? The truth is that too many academic institutions in the United States have become too dependent on military support for basic research. A great many of the chickens which have come home to roost in the past few months, among which the trouble at the Instrumentation Laboratory at MIT stands out, show that it would be hard even if it were desirable to recreate the old pattern of military expenditure on research.

What is the alternative? The first thing to be said is that military support for academic research has been necessary in the past only because the agencies set up for just this purpose have been badly provided with money. It follows that last week's events in Congress do not make less urgent the need to strengthen the National Science Foundation. The hope that the foundation's budget will be much larger in the coming financial year (for which plans are already being made in Washington) is known to recur annually and the experience of the recent past suggests that it is only improbably fulfilled. Between 1970 and 1971 the National Science Foundation's budget will have been increased by some 7 per cent, enough to make up for inflation but not to make good the neglect of recent years. If there is not a budget of more than $700 million for the financial year which begins in July 1971, the whole scientific community in the United States will be right in thinking that it has once more been asked to accomplish the impossible with impossibly meagre resources. The danger now is that the softening of the effects of the Mansfield amendment will be represented by the Administration as a sign that the National Science Foundation can go short of funds for yet another year. That would be intolerable.



Two Ways to the Moon

THE success of last week's Russian rocket to the Moon—Lunar 16 as it was called—has presented the United States National Aeronautics and Space Administration with something of a problem, particularly now that the end of the present series of Moon landings is in sight (see page 110). Since the beginning of the Apollo programme, there have been fierce arguments that the project for landing men on the Moon has been too expensive and in any case unnecessary. Although at first, in the early sixties, the Russians were clearly at pains never to suggest that the first astronauts would not be Russian, more recently they have been extolling the virtues of automatic go and return vehicles to the Moon. They are probably right in claiming that a single visit to the Moon by Lunar 16 costs 5 per cent or less than the cost of a single Apollo journey, but the relative usefulness of the two methods for the exploration of the Moon is not, of course, as easily determined as a comparison of costs suggests. The utility of the Russian method will depend on the extent to which samples of the surface can be collected with discrimination and, ultimately, on the ease with which it will be possible to move instruments from one place to another on the surface of the Moon. Evidently the Russians have a long way to go before their technique is properly developed. The prospect that it could be used for collecting regular samples from the Moon and bringing them back to Earth must, however, be a source of serious disquiet in Washington. The folly

of the Apollo programme, with its excessive dependence on cumbersome techniques of launching people into space, is now plain for everybody to see. The practical question is how quickly NASA will be able to duplicate the work the Russians have been carrying out, for there seems no doubt that competitiveness will decree that there must be such an attempt. Most probably, it will be two or three years before the first automatic Moon landing from the United States is carried out. By then, the memory of Apollo 11 will have begun to fade, if it has not done so already.

The implications of this dilemma for the future of the development of space flight in the United States are several. First of all, there can now be very little doubt that the ambitious plans for launching space shuttles and permanently habitable space stations are at once too ambitious and too cumbersome. As with the rest of physical research, so with space research, the best instruments are the most delicate. What this implies in practice is that there should be a greater concern in the United States with the potential scientific benefits of the exploration in space. There may be something in the view that it would have been better if the comparatively modest amounts which the Russians have spent on Lunar 16 had been spent on more mundane research.

100 Years Ago

Botanists and the Halfpenny Postage

FOR several years I have been in the habit of sending herbarium specimens by "book post," by merely placing the plants between sheets of white cardboard, which were invariably fastened by string, without wrappers, and the address written on the cardboard itself; so that, in fact, the parcel was open at both ends and sides. On Tuesday last I did up a small packet of green or living plants, and sent them to the village post-office. As the parcel weighed under four ounces, I affixed two halfpenny stamps. On calling at the post-office the next day, imagine my disgust at seeing my parcel of plants stuck up in the window to be sun-dried! Upon inquiry, I found that the postman had very *wisely* declined taking it to the borough office, as "several similar parcels were lying about there now, and would not be forwarded until the senders had prepaid the postage at letter-rate."

I say the postman acted wisely in refusing to take my parcel, because, on taking it to the Newbury post-office myself on Thursday, I found that unless I paid eightpence, or rather put on seven more penny stamps, *double* that amount would have actually been charged to the recipient, at which I should have felt much grieved, as the specimens were really not worth half the amount.

Another gentleman of my acquaintance sent a parcel to the same office with a fourpenny stamp on; this the clerk kindly *defaced*, and returned the parcel as "not sufficiently paid"!

I have read the new rules, and can see no clause bearing on this subject—either for or against herbarium specimens, or other objects of natural history, being sent between cardboard with open ends at the old rate of four ounces and under for one penny, and should therefore be glad of any correct information from you or the readers of NATURE.

East Woodhay, Oct. 7 HENRY REEKS

From Nature, **2**, 474, *October* 13, 1870.

OLD WORLD

SEWAGE

Epidemic Fears Exaggerated

IN the face of gloomy predictions of disease and disaster to follow the strike last week by sewage workers and other local authority employees in Britain, independent assessments of the risk to health by microbiologists were surprisingly and reassuringly in agreement with the official view of the situation. It seems, in the short term at any rate, that little danger to health should ensue from the inadvertent or inevitable discharge into rivers of untreated or partially treated sewage, even if the effluent is voided into rivers from which drinking water is drawn.

Mr G. E. Eden, assistant director of the Water Pollution Research Laboratory, said last week that the chief danger was not so much the immediate risk of epidemic arising from polluted drinking water but the long term prospect of mechanical failure in either the sewage pumping stations or purifying plants, resulting from an inevitable decline in the standard of maintenance while the machinery was being manned by unskilled volunteers. But failure or closure of the sewage pumping stations in the London area would precipitate a very grave situation indeed in which the risk of the flooding of low lying land would be added to the danger of epidemic.

Professor F. Fulton of the London School of Hygiene and Tropical Medicine pointed out that drinking water in Britain is tested and monitored so rigorously for faecal and bacterial contaminants that the immediate risk of water-borne infection is small. It is, of course, true that viral contaminants are very much harder to detect than those of a bacterial nature, and that certain water-borne viruses such as those causing infectious hepatitis are comparatively resistant to simple hygienic precautions such as boiling. Nevertheless, Professor Fulton thought viral infection to be a relatively slight risk.

London, among the first of the areas affected by the strike, is particularly well protected against water-borne infection, for drinking water supplied to the capital is stored, after treatment, for five to six weeks in special reservoirs before being fed into the domestic water system. These conditions are particularly unsuitable for the survival of microorganisms, and so this procedure is remarkably effective in maintaining the purity of the water supply.

Earlier this week the situation seemed to be well under control in the affected areas. In Bristol, where untreated sewage was being discharged directly into the River Avon, a local authority spokesman claimed that reports that people living near the river were "terrified" were based on misinformation. A spokesman for the Greater London Council said that all sixteen pumping stations in the London area were functioning, and that preparations had been made to keep them operating for at least a further week. It is to be hoped that by the time this article is printed, these preparations will have proved unnecessary, for all shades of opinion are in agreement that if the present situation continues for more than a few weeks, the consequences will be grave.

TOXICOLOGY

Government Chemist allays Fears

THE accumulation of pesticide residues in British food seems to be under control. This can be concluded from the *Report of the Government Chemist for 1969*, published last week (HMSO, price 18*s*). A survey during the past few years has shown that the concentrations of organochlorides such as dieldrin and DDT in milk, butter, beef kidney fat and mutton kidney fat have remained very low, and that in many cases they are diminishing. For this reason the examination of milk, butter and home produced beef fat has been discontinued. The details of a recent survey of organophosphate residues in the diet may also give rise to optimism, but the report points out that wildlife is still in danger from pesticides.

In his survey of the organophosphate pesticides in the total British diet (samples of the total diet were devised on the basis of data supplied by the Ministry of Agriculture), the Government Chemist found that the most common was malthion. This is probably because malthion is used in the treatment of Australian and Argentinian grain before shipment. But malthion has a low mammalian toxicity compared with other organophosphate pesticides, and after degradation during transportation and processing, the amounts present in bread, cakes, flour and biscuits are much less than the maximum safe amount recommended by the Food and Agriculture Organization of the United Nations and the World Health Organization. These findings are similar to those of a survey carried out in the United States.

The report also dismisses fears that mercury, a metal highly toxic to living organisms, may be accumulating in foodstuffs because mercurial compounds are being used on crops as fungicides as well as being carelessly discarded by industry. In cereals, fats, fruits and milk, mercury was present below the detectable level of 0·01 part per million. Between 0·01 and 0·015 p.p.m. was found in samples of meat, root vegetables and green vegetables. The report says that these results should "allay some of the concern about mercury contamination in the national diet".

Pesticides are also accumulating in tobacco. This is not surprising because they are used extensively on the tobacco crop. Virginia tobacco, for example, contains up to 11 p.p.m. of DDT, but although these concentrations are considerably greater than those usually found in foodstuffs, only 8–12 per cent of the residue is inhaled, and of this, much remains in the smoke exhaled. Nevertheless, the report says, this could be an important source of DDT to the heavy smoker.

The Laboratory of the Government Chemist has also been examining wildlife tissue on behalf of the Nature Conservancy. The principal pesticide residues found in the eggs, organs and tissues of birds were DDT (in a metabolized form) and dieldrin. The greatest concentration of polychlorobiphenyls (PCB) found so far has also been recorded. As much as 900 p.p.m. were found in herons. These chemicals were first regarded merely as contaminants in the analysis of the pesticide residues. They were identified in 1967 and have since been recognized as another serious threat to wildlife because their effect on reproductive metabolism is similar to that of the pesticides themselves. Together with the organochloride pesticides, they may be responsible for the aberration in calcium metabolism which has been observed in many species of birds since the Second World War. Calcium metabolism in birds is intimately related to reproductive metabolism and is to a large extent regulated by the steroid sex hormones. The organochlorides are thought to induce hepatic enzymes that degrade the sex hormones.

ACADEMIC FREEDOM

Flying Start for New Council

THE view that career prospects are worsened for unorthodox or nonconformist academics wasput forward by Professor John Griffith of the London School of Economics at a conference at Imperial College, London, on October 3 to launch the Council for Academic Freedom and Democracy (see *Nature*, **227**, 1180; 1970). "It is very depressing that many colleagues have shown a great unwillingness to support those under attack," he said, saying that a member of the staff at LSE last year confided that although he deplored the way the authorities dismissed Mr Robin Blackburn from his lectureship last year, he could not say so publicly with a wife and two children to support.

The chief purpose of the new council will be to provide machinery to investigate cases such as those of Mr Blackburn and Mr Richard Atkinson, the man who was refused a lectureship at Birmingham University on what seem to be clearly non-academic grounds. In the minds of the 150 university teachers who attended the conference, the "Atkinson case" crystallized the dissatisfaction felt about the structure of universities and institutes of higher education in Britain. The plain fact seems to be that the Academic Appointments Board at Birmingham had refused Mr Atkinson a lectureship in sociology on the grounds that he had associated with students who were demanding the implementation of plans to democratize the structure of the university. The departmental selection committee had voted by five votes to four to offer him the post, and his former colleagues at the University of Manchester had warmly endorsed his ability as a teacher. His former students also found him an excellent teacher and found no political bias in his methods.

The debate about the posture which the new council should adopt turned out to be a lively encounter between those who saw it as a pressure group closely tethered to the Association of University Teachers, and those who wanted it to be a more independent body which would attract "middle of the road" lecturers. In the event, the conference settled on a compromise by which the CAFD, linked to the National Council for Civil Liberties, would draw on the NCCL for administrative and legal advice but would work closely with the AUT.

The chief danger of linking arms with the AUT and the Association of Teachers in Technical Institutions, Professor Griffith warned, is that members of these unions may themselves be involved on opposite sides of a dispute. Mr A. Booth of Harlow Technical College recalled that in many technical colleges the Principal, who wields more power than in most universities, was often also an official of the ATTI.

Mr W. Stephenson of Bedford College, London, pointed out that the AUT already has a commitment to democratization of university structures and that

it had shown its teeth by financing the defence of the three lecturers dismissed from the LSE, two of whom were later reinstated. This had cost the AUT £2,000. Another speaker warned that the public might see the CAFD as a weapon for fighting student militancy rather than government and university oppression. Encroachment of freedom from governing bodies and indeed industry was much more subtle and harder to combat.

Mr Richard Atkinson counselled against making the CAFD too specialized a body. "We must see ourselves as having interests intimately bound up with people in technical colleges and with students, people who have far more institutionalized unfreedom than we have," he said. He saw a danger of the same chasm developing between left wing students and liberal staff as had appeared in the United States.

RESEARCH PROGRAMMES

Space and Atomic Energy in India

An inadequate road and rail system seems to be one of the chief obstacles to the construction of nuclear power stations in India, according to a document now published by the Indian Atomic Energy Commission (*Energy and Space Research: A Profile for the Decade 1970–80*). Without a programme for the improvement of roads, the strengthening of bridges and so on, heavy items of equipment cannot be transported from the factories to potential sites for power stations. In the circumstances, it is anomalous that India is planning a space programme which is expected to cost £91·5 million during the next ten years. India's ambitions roughly match those that European organizations such as the European Launcher Development Organization and the European Space Research Organization have been mulling over during Professor Bondi's tenure as director-general. By the end of the 1970s India hopes to be able to launch 1,200 kg satellites into geostationary orbits.

Since 1961, space research in India has been under the wing of the Department of Atomic Energy. The programme is based on about 75 sounding rockets per year, chiefly for straightforward studies of the upper atmosphere and for X-ray astronomy. The reasons for turning this modest and reasonable programme into an attempt to join the countries with an indigenous launcher ability—at present the Soviet Union, United States, France, Japan and China—is vague. There are the usual unsupported platitudes about applications of satellites and, to be fair, India has a lot to gain from applications such as direct television, but there is also the argument that a space programme will drag Indian metallurgy, electronics and computing into the second half of the twentieth century.

Against this background, the plans for the development of atomic energy in India, the tidiest way of generating the electrical power that a developing country needs, have more sense in them. Even so, it is clear that the programme is not going well. If the present targets are attained, then by 1980 only six per cent of the electrical power in India will be generated by nuclear stations, compared with 22 per cent in Japan and nearly 30 per cent in Britain and the United States.

The Atomic Energy Commission is working on the principle that it is economic to use nuclear power in areas more than 600 miles from a coalfield. During the next ten years the plan calls for the building of reactors using natural uranium and moderated by heavy water, which will provide the plutonium for the fast breeder reactors to be developed for the 1980s. Between 1980 and 1985 the fast breeder reactors will be supplying ^{233}U for use in thorium cycle reactors. These reactors will be developed in the early 1980s for use after 1985. The reserves of thorium in India are thought to be roughly ten times the uranium reserves.

During the current five-year plan which runs from 1969 to 1974, about £141 million is earmarked for atomic energy, and Table 1 shows how the Atomic Energy Commission would like the spending to increase by 1980. By then the intention is to have 2,700 MW of installed capacity, which means that before 1974 building will have to start on five new stations totalling 1,700 MW.

ESTIMATED COST OF THE ATOMIC ENERGY PROGRAMME
(in millions of rupees, £1 sterling = 18·04 Rs)

	1970–75	1975–80
1,000 MW constructed or under construction	1,010	290
3 × 235 MW	440	1,860
2 × 500 MW	50	2,700
Design of 500 MW advanced thermal reactors	50	—
Fast breeder test reactor and research centre	320	230
Augmentation of heavy water production	750	200
500 MW fast breeder reactor	—	1,250
Gas centrifuge technology	100	1,000
Narwapahar uranium mines	40	140
Nuclear fuel complex	130	—
Reprocessing plants for plutonium	90	140
Bhabha Atomic Research Centre	650	1,000
Isotope applications	20	40
Total	3,650	8,850

The space research programme is more esoteric. At a cost of about £1·7 million for the development of the launcher, and slightly less for the development of a scientific satellite, India hopes to launch a 30 kg satellite into a 400 km orbit during 1974. The launcher for geostationary satellites is expected to cost about £8·6 million during the decade, and about £15 million is to be spent on a communications satellite. During the same period about £1·4 million will be spent on guidance systems and onboard computers. Much of the work will be done at the Space Science and Technology Centre which was established in 1965 close to the Thumba rocket range, on the geomagnetic equator in South India. Thumba is a sounding rocket range, however, near a densely populated area, and a range for satellite launches is being built on Sriharikota island, about thirty miles north of Madras on the coast of the Bay of Bengal. By December this year the range is expected to be in use for sounding rockets, and a year later for larger multi-stage rockets. Sriharikota will also contain the plant for the manufacture of the satellite launchers and testing laboratories. By 1980 the report estimates that 7,000 people in India could be involved in space research in India.

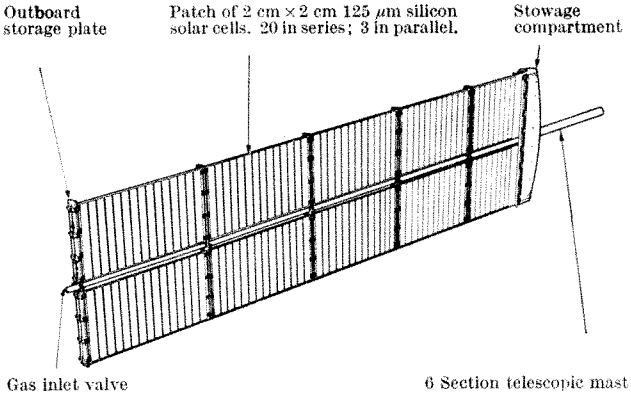
RESEARCH FUNDS

Selectivity to Stay

THE Science Research Council will continue to concentrate funds on a few centres of high activity in universities, applying the test of usefulness to industry. The council's chairman, Sir Brian Flowers, made this clear on October 2 when he opened the new computer laboratory at the Control Systems Centre of the University of Manchester Institute of Science and Technology. The laboratory has been equipped by means of a grant of £360,000 from the SRC, which has concentrated its support for control engineering on Manchester, Cambridge and Imperial College, London. Such selectivity, Sir Brian said, would continue, being all the more necessary in the present conditions of financial stringency.

He explained that the SRC recognized three phases of research. First there was the stage of testing new ideas—the most important and least predictable stage, and also the least expensive to support. Next came the recognition and promotion of useful ideas—the development stage. This was the stage when selectivity came in. The SRC's two major criteria in judging the worth of a project at this stage were the likelihood of it being a major breakthrough and its industrial significance. The third stage, Sir Brian said, was the application of a new development, when its scientific basis was well understood. By this time concentration of resources in a few centres was absolutely vital. Unless selectivity and the test of industrial usefulness were applied, the SRC would need three and a half times its present budget, according to Sir Brian.

SRC grants to the Control Systems Centre at UMIST have now totalled about £450,000. The centre was set up in 1966, to run an MSc course and provide services to the institute for control work. Since then the centre, under its director, Professor H. H. Rosenbrock, has acquired its present complement of four computers and attendant equipment. The new laboratory, which has been named after Sir Harold Hartley, a pioneer of control systems, should be the scene of increasing application of the centre's work to industry.



Work in progress includes the development of a mathematical model for the control of a new steel making plant for the British Steel Corporation. Other projects are concerned with problems in the control of processes connected with the production of glass, cement and plastic sheets. There is also a growing interest in the application of control to medicine, and work is well advanced on the control of a kidney machine, in collaboration with the Manchester Royal Infirmary. A small laboratory at the centre is to be devoted to medical engineering work.

SATELLITES

Lightweight Solar Sails

THE Royal Aircraft Establishment at Farnborough has now gone far enough with the development of a lightweight solar cell array to exhibit a prototype flight model. Such an array is meant to provide power for the X4 experimental meteorological satellite due to be launched by the 1972 Black Arrow firing. But it is possible that an additional technological satellite so powered for the Black Arrow programme will be inserted in the schedule between next year's X3 and the X4.

Compared with the original Farnborough concept of the lightweight array, generally called the "toilet roll", the new version is better described as a "sail". The cells, fairly conventional thin silicon wafers in themselves, are mounted on heat resistant plastic sheet only two-thousandths of an inch thick. This material, 'Kapton' (made by Dupont), besides being tough and light, has the advantage of being able to withstand temperatures from −200° C to 400° C. The array is folded like a concertina into a cushioned compartment for launching, and is then deployed pneumatically by a light telescopic mast in orbit (see diagram). The prototype array, similar to that to be flown on X4, will have an area of about one square metre.

The advanced solar cell array developed at the Royal Aircraft Establishment.

The advantage of the development (thought to be without rival) is that it has a power to weight ratio three times greater than normal solar cell arrays—53 kW per kg. Multikilowatt arrays could provide power for the next generation of communications satellites and for long-life unmanned probes to the planets. In conjunction with the ion engine, which yields low thrust over periods of months but with high demands on power, it has been suggested the new device could also help to wind a low orbit communications satellite out to geostationary distance if time were no object. It might take some months, taking into account periods of "coast only" when the satellite was eclipsed from sunlight by the Earth.

LABOUR PARTY

All Quiet on Science

THE Labour Party conference in Blackpool last week produced little to excite technologically minded members of the community, with the exception of a lively debate on pollution. It was disappointing to see matters apparently ignored which were considered of prime importance during the term of office of the last Government; there was singular lack of reaction, for example, to the now very compelling rumours about the fate of the Ministry of Technology and the possible amalgamation of some of its functions with those of the Board of Trade. And chemical and biological warfare, although on the conference agenda, was not

eventually discussed. Is the role of science and technology now so well accepted within the Labour Party that it can be overlooked with impunity?

Mr Anthony Wedgwood Benn, formerly Minister of Technology, gave stern warnings at the end of the nationalized industries debate against moves to sell into private hands profitable public sectors such as telecommunications with its well developed research and development facilities. He said that a future Labour Government would not compensate purchasers of denationalized industries.

A seven point plan for the prevention of pollution was put forward by Nottingham Central Labour Party and, during the debate, the present Conservative Government was criticized both for making only a junior minister responsible for a matter of such basic importance and for failing to see the problem as one to be handled by long term planning. Industry, as one of the chief villains, would be considerably restricted under the Nottingham plan; factories would have to treat their effluent on site and a severe limit would be imposed on the industrial emission of sulphur dioxide. At a more personal level, the further control of vehicle exhaust and measures to tighten up tests on chemicals and drugs before marketing figured prominently.

MEDICAL RESEARCH

MRC—University Symbiosis

THE comparative affluence of the Medical Research Council is leading to a shift in its role as a funding and organizing agency. Traditionally it has been a somewhat passive sponsor of research, taking the initiative whenever there was felt to be some gap in the national effort, but otherwise occupied with the care of its own units within the hospitals and universities and the provision of grants to those who came knocking on its door. The MRC is now to establish at its headquarters office a Universities, Grants and Training Awards Division with the specific objective of promoting liaison with the universities and strengthening the more informal means of communication which already exist.

So far the MRC has not suffered as much as most agencies—including the University Grants Committee—in the limitation of funds and this makes it one of the more attractive organizations with which to liaise. None the less, there is clearly an image of remoteness to be removed, and Dr Brandon Lush, who is to head the new division, will seek to bridge this gulf. The aim is not necessarily to make it easier to gain access to the coffers of the MRC, but to tell the universities more about the council's policies and to hear more directly about the needs of the universities.

The changes necessitate reorganization at head office. Last year saw innovation in the form of grants committees to help assess the merit of applications for support and there has always been a grants section at MRC headquarters. Even so, there have been signs of strain and the new division is at once a symptom of the increasing call on MRC funds and an acknowledgment of remaining inadequacy in the machinery for making awards. So long as rumours of the government's disenchantment with the research councils remain unfounded, the MRC can hope to improve both its efficiency and its public image and extend its influence as a power in the land.

COUNTRYSIDE

Save Britain's Coast

by our Planning Correspondent

THIRTY-FOUR stretches of coast, representing the finest coastal scenery in England and Wales, have been selected by the Countryside Commission from the 2,054 miles of largely underdeveloped coastline for designation nationally as "heritage coasts". The commission wants such areas, which total some 27 per cent (730 miles) of the English and Welsh coastline, and which are all more than a mile long, to be specially managed by local authorities so that they are protected from incongruous development and from pressures imposed by too many visitors. The commission's policies for the management of these coastal areas are set out in the two final reports (*The Planning of the Coastline*, 17*s* 6*d*; *The Coastal Heritage*, £4, HMSO) in its study of coastal preservation and development. These are the last of a series of reports which have been appearing since 1967.

The commission does not want to keep visitors away from the heritage coasts, which include the Seven Sisters and Beachy Head and the Isles of Scilly—indeed it recognizes that the demands for recreation in some of its proposed special areas will be particularly heavy because of their attractions. But to reconcile these demands with the safeguarding of the area's natural scenery, there must be positive policies for management. *The Coastal Heritage* suggests some fundamental principles to ensure effective management. One suggestion is that the scale of recreational activities and of the provision of facilities for visitors should be related directly to an optimum level of use. To achieve this, each stretch of coastline should be divided into three zones with an agreed level of use. There should also be regulations of access for people and vehicles at places where an excessive concentration is likely to cause damage. Rigorous control over development, emphasis on the opportunities for different forms of recreation, and information services are also urged. Each local authority should also appoint a conservation officer who could advise a special committee on the management of the heritage coasts.

In preparing *The Planning of the Coastline* the commission has looked more generally at the English and Welsh coastline in terms of the changing patterns of holidaymaking in Britain, and the effects of these changes on the coast. In addition to recommending compact new holiday centres, it wants the government to give it powers to designate regional parks in coastal areas which offer good opportunities for recreation, such as Chichester Harbour. The powers and organization of the authorities set up to administer these parks could, the commission suggests, be modelled on the present national parks. The commission is also critical of the eyesores which remain on the coast, in particular the colliery wastes on the foreshores of Northumberland and Durham, and defence structure in many places, and it says that target dates should be set for the removal of the messes by local authorities. The commission repeats its request, made in 1968, to look into the exploitation of reserves of gas and oil off the coast, saying that such a commission is an essential preliminary to the formulation of a national policy on the planning aspects of these industries.

NEW WORLD

Mansfield Amendment Cut Down

by our Washington Correspondent

THE law requiring that all the research sponsored by the Department of Defense should be of direct military relevance has become a dead letter, although it will probably continue to exert its influence from beyond the grave. The law, known as the Mansfield amendment to last year's military procurement authorization act, was re-included in the bill for the present financial year by the Senate but not by the House of Representatives. In negotiations between the two chambers reported last week, the delegates from the Senate were forced to yield on the Mansfield amendment in return for House concessions on other points in the bill, notably the Senate's stand on limiting the Safeguard anti-ballistic missile system to defending only missile sites. The importance of the amendment is that it knocked away the most conspicuous pillar of American science policy, the practice whereby the bulk of Federal support of science is channelled through the large mission oriented agencies such as the Department of Defense, instead of through the relatively puny National Science Foundation.

The price paid by the Senate for its position on the ABM was to allow the House to sabotage the Mansfield amendment beyond repair and to adulterate a corollary provision that the budget of the National Science Foundation should be increased. The crucial wording in the Mansfield amendment, that no research project should be supported by the Department of Defense "unless such project or study has a direct and apparent relationship to a specific military function or operation", has been replaced by the jejune stipulation "unless such project or study has, in the opinion of the Secretary of Defense, a potential relationship to a military function or operation".

This language was arrived at after rejection of a compromise Senate proposal that would have distinguished between applied and basic research, using a test of strict relevancy for the former but asking only for "clear potential relevancy" on the latter. But the House conferees were adamant that no restriction should be placed on the Pentagon's freedom to conduct whatever basic research it wanted, and insisted that the concept of military relevancy "should not be used as the determining factor in the support of basic research efforts of contractors, universities, or non-profit institutions".

The House conferees also took exception to the Senate's indication that the budget of the National Science Foundation for the financial year starting in July 1971 should be increased by a fifth. The reason given was that "this matter had not been a subject of House Committee hearings and therefore was not a matter on which the House members were prepared to act". The House Subcommittee on Science, Research and Development has held extensive hearings on the general issues involved, though not on the Senate proposal specifically, but these do not seem to count for much with the House Armed Services Committee, whose conferees were in charge of the negotiations. As a result the Senate's call for a stronger role to be played by the National Science Foundation has come out much watered down.

The Senate also had to give way on its proposal for an Interagency Council on Domestic Applications of Defense Research, which would have sought to convert the resources of defence industries, now underutilized because of budget cutbacks, to the solution of domestic problems. The House conferees argued that this type of coordination was the job of the Federal Council for Science and Technology but in any case they were unwilling to accept the Senate view of the matter since the House Armed Services Committee had not held hearings on it.

In the debate on the conferees' report Senator Mike Mansfield made no secret of his disappointment at the concessions that had been made. The alteration to his amendment, he said, is worse than eliminating it altogether since it "affirmatively states that the Department of Defense will solely determine what research is beneficial to it. This language, in my opinion, is a legislative act of abdication to the Secretary of Defense . . ." The Senator still hoped for "an alignment not only in what is necessary for military and scientific development . . . but also in that which can be allocated to the National Science Foundation and other civilian agencies engaged in basic research. . . ." Mr Mansfield gave notice that his fight to achieve this reallocation was far from ended, it had just begun again.

The virtual repeal of the Mansfield amendment will give the Pentagon less freedom to continue its support of the full spectrum of basic research—its "backdoor National Science Foundation", as Senator Mansfield has termed it—than in the days when Congress happily disbursed whatever the generals said was needed. But although in the short term the demise of the amendment may allow more funds for basic research, the long term prospects, even if the amendment is not resurrected next year, are less certain. Mr Mendel Rivers, the chairman of the House Armed Services Committee, has gelded the Mansfield amendment not because he thinks it may harm science but because it does no obvious good to the Pentagon. In Senator Mansfield's mind too, the thought of cutting the Pentagon down to size may loom larger than that of building up the National Science Foundation, but at least the Senator has laid out a logical and constructive design of how he envisages science should be supported. The whole question of science funding has now been thrown back into the political arena where it stands to be decided not on its own merits but as part of the tussle between the friends and foes of the Pentagon. To this extent the Senate's sacrifice of the amendment is a doubtful benefice.

NAS, AAAS to Report on Vietnam Defoliation

by our Washington Correspondent

NINE years after the start of the defoliation programme in South Vietnam, the Department of Defense is to commission a study of the programme's physiological and ecological effects. A clause in the military procurement authorization bill requires the Secretary of Defense to ask the National Academy of Sciences to conduct an appropriate survey. The clause came to light last week in the report of the agreement between House and Senate conferees on the rival versions of the bill passed by each chamber.

The language of the clause (Subsection 506c of the bill) calls for a study of the "danger inherent in the use of herbicides" and mentions the defoliation programme specifically. Apart from the general reference to herbicides it is not clear how far the proposed study will include the crop destruction programme, which may be being pursued no less actively than the defoliation of forests and mangrove swamps.

Preliminary discussions have taken place between the Office of Senator McIntyre, chairman of the Armed Service's Committee's Subcommittee on Research and Development, and the National Academy, but a formal proposal has yet to be made. Agreement will have to be found on such questions as whether the members of the study will include Vietnamese scientists and, in particular, on how far the findings should be made public. Although the academy rarely refuses to undertake research projects requested by the government, there has been vigorous discussion among members on the propriety of undertaking classified research.

Any survey the academy may agree to undertake is likely to run into problems of military secrecy since the Pentagon, at least on present showing, is intent on withholding certain information essential to a scientific study of the use of herbicides in Vietnam. A pilot study sponsored by the American Association for the Advancement of Science is being seriously impeded by the refusal of the Department of Defense to allow access to the record of the crop and forest spraying missions conducted in South Vietnam since 1965.

A study group appointed by the AAAS visited South Vietnam in August after receiving a formal invitation from the Vietnamese government. The members of the group were Matthew Meselson, professor of biology at Harvard University, Arthur Westing, a forester knowledgeable in the use of the herbicide 2,4,5-T; Robert E. Cook, a graduate student of ecology at Yale University, and John D. Constable, professor of surgery at the Harvard Medical School. In company with Vietnamese scientists, including a professor of botany, the group spent four and a half weeks surveying sprayed areas, interviewing farmers and taking samples of soil, fish, mother's milk, hair and various links in the food chain.

The group's instructions from the AAAS were to "study the long and short term effects of the military use of herbicides on the land and people of Vietnam". Findings will be reported at the annual meeting of the AAAS in December, but unless the Department of Defense releases its records of spraying missions the scientific value of the samples and observations collected by the group will be seriously limited.

The crucial records consist of a hand-kept log book, maintained in Saigon, in which are entered the date and map coordinates of all spraying missions flown since July 1965, together with the nature of the mission (whether crop spraying or defoliation), the number of hectares covered and the number of bullet holes counted in the aircraft on return to base.

Meselson said last week he is puzzled at the willingness with which the AAAS group was told the time and place of spraying missions carried out immediately before and during its time in Vietnam—information which could possibly be of military value to an enemy—compared with the refusal of defence officials to release the same data for all earlier missions, which it is hard to see could be of any military value. The refusal is the more surprising since Ambassador Ellsworth Bunker supported the group's request for access to this information.

Whatever the detailed conclusions of the AAAS group turn out to be, there is no doubt that any untoward ecological effects of the herbicide programme will be or are being felt extensively throughout South Vietnam. Since 1965, when the defoliation programme began, a third of the country's forests—amounting to 15 per cent of the total land area—and about half the mangrove swamps have been sprayed. The AAAS group has confirmed a survey conducted in 1968 by Fred Tschirley, a scientist with the US Department of Agriculture, that extensive areas of dead forest have been invaded by bamboo. Destruction of the forests is serious not only ecologically but also because in Vietnam's future economy forest products could play a leading role. In the mangrove swamps, by contrast, there is little or no evidence of regeneration in sprayed areas. Under the crop destruction programme half a million acres of crop land had been sprayed by 1968. Probably some 30,000 herbicide-spraying sorties have been flown in South Vietnam by fixed wing aircraft (there is no central record of helicopter missions) since 1964.

The principal herbicides used in the two programmes are picloram, cacodylic acid, 2,4-D and, until recently, 2,4,5-T. Besides any harm it may do on its own

account, 2,4,5-T (2,4,5-trichlorophenoxyacetic acid) contains small quantities of an impurity created in the manufacture, 2,3,7,8-tetrachlorodibenzo-*p*-dioxin. The dioxin compound appears to be the most poisonous chemical known, excluding certain protein toxins but not the nerve gases. In the guinea-pig dioxin is lethal in concentrations of less than 1 mg/kg, or one part per million, which is comparable with the toxicity of VX nerve gas. A perturbing feature of dioxin is that, unlike other toxins, it is most surprisingly quite inert chemically. Its planar structure suggests that it could be forming complexes with important molecules such as nucleic acids. Whatever its mode of action, dioxin may be stable enough to work its way up food chains and to accumulate in body tissues. Commercial preparations of 2,4,5-T contain amounts of dioxin that vary from one manufacturer to another (that from Dow Chemicals contained the least since the corporation had been aware of some of the untoward effects of the impurity since 1964), but it can be estimated that something of the order of 100 lb of dioxin has been sprayed over South Vietnam since the herbicide programmes began. It is not yet known what has happened to this material.

The biological samples brought back by the AAAS group may hold some of the answers, although Meselson emphasizes the necessary limitations of a study undertaken "in the middle of a hot war, by a group of people who are not experts in tropical ecology". There has been an unusually direct connexion between the scientific discovery of the chief herbicides and their use for military purposes. The herbicides 2,4-D and 2,4,5-T were developed during the Second World War by E. J. Kraus, chairman of the Department of Botany at Chicago University, with the deliberate intent that they should be used for crop destruction. This was opposed at the time on humanitarian grounds, chiefly by Admiral Leahy, and the same arguments prevailed during the Korean war. The question of using the herbicides for military purposes arose again in the early stages of American involvement in the war in Vietnam, and after an initial refusal President Kennedy gave permission for a programme of spraying herbicides alongside roads. Large scale spraying of crops was not begun until 1964, and the defoliation programme the following year. At the height of the defoliation programme some 4,000 square kilometres were being sprayed a year, but, following the replacement of General Westmoreland as American military commander by General Creighton Abrams, the strategic need for clearing large forest areas diminished and the defoliation programme was reduced by about a fifth. In particular a review of the programme initiated by Ambassador Bunker in 1968 resulted in a switch from the block spraying of forests to spraying in strips, a practice which it was thought would allow the sprayed areas to be reseeded from the unsprayed. But the crop destruction programme is still proceeding actively.

Whatever the ecological consequences of the herbicide programmes turn out to be, they are unlikely to be as irreversible as the effects on society. On one occasion the AAAS group witnessed the spraying of rice fields which, on the basis of aerial reconnaissance, had been judged to be cultivated by or for the Vietcong. Visiting the area by land a few days later, they learnt the fields belonged to Montagnard tribes people who were abandoning their land because of the evident pestilence under which it had fallen. Overdue though they may be, the studies by the AAAS and the National Academy of Sciences are at least a start towards understanding some of the possible long term effects of the pestilence.

WATER POLLUTION

One Detergent for Another

by our New York Correspondent

DETERGENTS have recently become a dirty word, politically at least, as more and more individuals and organizations have jumped onto the ecological bandwagon. Nelson Rockefeller, governor of New York, who is running for re-election in November, joined the band last week when he announced that he would propose in the 1971 legislature a ban on the sale of detergents containing phosphates in New York State by 1972.

Many environmentalists claim that phosphates are the main contributors to excessive eutrophication in lakes. Phosphates are considered to be the nutrient that controls the growth of algae. Excessive algae consume the available oxygen, and other life forms in the lakes eventually die. There is now some research to show that phosphates are not always the limiting nutrient and that often carbon performs the same function in some lakes, but in either case sewage wastes are still to blame. Disregarding the carbon theory, Governor Rockefeller and others seem to believe that if only phosphates can be removed from detergents, one of the major sources of phosphate wastes found in industrial and municipal sewage, the problem would be solved. Unfortunately things are never that easy.

The detergent manufacturers in turn claim that they are well aware of the problems and public concern over phosphates, and that they have been spending most of their research money searching for substitutes with little to show for it. They also claim that the proverbial American housewife, not to mention users such as hospitals and restaurants, would be unwilling to return to the "tell-tale grey" and germs of pre-detergent days.

Present detergents, the manufacturers point out, have been studied and tested for many years, and their ecological effects are well understood if not totally under control. Until possible alternatives have been subjected to equally rigorous testing, the companies argue that it would be foolhardy to invest large sums in new projects and equally impossible for legislatures to ban the present detergents before there are adequate substitutes.

In the meantime the manufacturers are being urged to promote detergents with lower amounts of phosphate and to experiment with nitrolotriacetic acid (NTA) as a partial substitute. NTA certainly seems to work well in conjunction with lower phosphate levels, but it, too, is running into problems. In the first place experiments on rats at Procter and Gamble over the past two years have shown that massive doses of NTA can cause nephrosis, a kidney disease. Procter and Gamble argue that this does not imply that the chemical is toxic for humans. Dr Samuel Epstein, a pathologist at the Harvard Medical School, has suggested that the nitrates produced by bacterial breakdown in sewage may combine with secondary amines to form nitro-

amines, some of which cause cancer. Detergent manufacturers seem confident that these fears will prove unfounded, but they agree that much more research needs to be done on the effects of NTA before it becomes widely used.

In any case, NTA is not being produced in sufficient quantities to substitute fully for the two billion pounds of phosphates at present used yearly in detergents. The two major producers of NTA in the country, Monsanto Company and Grace's Hampshire Chemical Unit, only manufacture about one hundred and fifty million pounds a year. By 1971 Monsanto expects to be producing only 350 million pounds a year. P and G, the company most heavily committed to NTA, expects to replace NTA for phosphates in nearly a third of its detergent production by 1972 while Lever Brothers, another major producer, said recently that "the question here is that we are still awaiting federal research on the safety of NTA if it is used in large quantities by industry as a replacement".

Whatever the final answer is on NTA it will be very difficult for any legislation banning phosphate detergents to be effective by 1972, no matter how politically expedient such a ban would be in an election year. In any case detergents are not the only villains in this piece. While it certainly simplifies things for the government when it can blame one industry for the problems caused by many, simply eliminating detergent phosphates still leaves many sources of phosphates to ruin the lakes. A far more effective though more expensive solution is adequate sewage treatment; by treating all wastes before they are discharged back into the water supply, all such problems would be solved at their source. Unfortunately, this would be another toll on the taxpayer, something that Governor Rockefeller is well aware will not win him votes on election day, even in a supposedly ecological era.

LUNAR SCIENCE

NASA Aims for Putrid Marsh

by our Astronomy Correspondent

LAST week the National Aeronautics and Space Administration announced that the destination of the Apollo 15 mission next July will be the Hadley rille (26° 52′ N, 3° 00′ E), which meanders through a flat region with the unfortunate name Palus Putredinis (Marsh of Putridity). This leaves only the two final sites to be decided before the American exploration of the Moon ends for the foreseeable future in June 1972. Of these two sites the first (Apollo 16) is expected to be Descartes (10° 10′ S, 16° 35′ E), a highland area marked by signs of volcanic activity, although this is dependent on good photographs of the area being taken during the Apollo 14 flight to Fra Mauro which is due to be launched on January 31. In spite of the tight schedule of modifications to Apollo 14 that are being made as a result of the Apollo 13 accident, Dr Rocco A. Petrone, the Apollo programme director, sees no problem in meeting the January 31 deadline.

Following the cancellation last month of a further two Apollo flights, which among other things is expected to free between $600 million and $900 million for the controversial space shuttle programme, the selection of landing sites has become even more important. The Hadley site should provide samples of the Mare Imbrium material and of the Apennine mountains, but it is disappointing that material which would give clues to the origin of the rille will not necessarily be forthcoming. The rille is 600 feet deep, and as far as the planning goes at present the astronauts are not expected to do more than scramble a few feet down the side. Even that depends on the slope—the steepest that can be tackled is probably 20°—and on the state of the ground.

NASA sees no problem in landing considerably further from the lunar equator than the previous sites or in the approach to the landing site which will be over the 8,000 feet high Apennine mountains. Apollo 15 is the first of the J missions which have an enhanced scientific potentiality chiefly because of the addition of a simple vehicle to the payload. Two of the three traverses planned for the mission will use the vehicle, taking the astronauts up to 8 km away from the lunar module along the edge of the rille and to the foothills of the Apennines. Apollo 15 will also carry an improved laser reflector with 300 instead of 100 corner reflectors so that it can be used by smaller observatories, and a seismometer which may throw more light on the positive gravity anomaly in Mare Imbrium. And this will be the first flight of a package of instruments which fit into bay 1 of the service module. The package includes a mass spectrometer, X-ray, gamma ray and alpha particle spectrometers, a laser altimeter, cameras for accurate mapping of the Moon, and a small satellite to be released into lunar oribit, chiefly to map the gravity field but also for particle and magnetic field measurements. The presence of the cameras in part of the spacecraft that is discarded before the return to Earth implies that there will have to be a spacewalk by one of the astronauts during the flight home to retrieve the film.

Awards for Heart Research

Sir George Pickering, Master of Pembroke College at the University of Oxford, and Dr Irvine H. Page, of the Cleveland Clinic Foundation, were named on September 23 as the joint winners of this year's $50,000 Stouffer Prize for Research in Heart Disease. It is to be awarded in recognition of their contribution to the understanding of arteriosclerosis (hardening of the arteries) and hypertension (high blood pressure). This is the fifth year that the award has been given.

Sir George was professor of medicine at the University of London and director of the Medical Clinic at St Mary's Hospital from 1939 to 1956. Until 1969, he held the chair of medicine at the University of Oxford, once held by Sir William Osler. Dr Page has studied the heart and circulation since 1937 when he became director of the Lilly Laboratory for Clinical Research at the Indianapolis City Hospital. He joined the Cleveland Clinical Foundation in 1945 and became president of the American Heart Association in 1946.

Their work has led to many of the therapies that have been so effective in recent years in the treatment of hypertension, the most prevalent of all cardiovascular diseases.

NEWS AND VIEWS

Hot and Cold from Nimbus

THE cause of improved temperature mapping of the atmosphere and, as a consequence, improved weather forecasting, was taken one step further by the launching in April of this year of Nimbus 4, one of six satellites in the NASA Nimbus programme. The cooperation between research groups at the Universities of Reading and Oxford has enabled a radiometer of British design, and embodying several novel principles, to be used as a self contained piece of equipment in an American satellite. Development work on this radiometer was started in 1961 and it is now possible to observe a large number of infrared lines in the CO_2 spectrum simultaneously. Data on atmospheric temperatures are extracted from the ratios of measured vertical intensities of radiation energy emitted at the infrared wavelengths together with the known variation of the absorption properties of the atmosphere with wavelengths. The results of its first few months of operation have come right up to expectations and some rather unexpected facts have been brought to light, which are described on page 139 of this issue of *Nature*.

The importance of atmospheric data (particularly temperatures) for weather forecasting is a consequence of the inherent difficulty of the study of medium scale air motions affecting areas about five or six hundred kilometres across. By contrast, air motions over areas of continental size are fairly well understood and predictions can be made by computer methods although there is a continual need for larger and faster computers.

The Reading/Oxford infrared radiometer has been used to plot the temperature distribution in several layers of the atmosphere (each typically 5–10 km deep) with an accuracy better than 2° C. The results so far indicate that at the 45 km level the temperature distribution is not as expected around the poles and that at the south pole, in particular, there are two distinct cold spots where intuitively only one would be expected. The shape of the temperature distribution in this layer seems to change dramatically with time, but these changes are not reflected to any great extent in lower atmospheric layers. Explanations of the cold spots are not yet forthcoming, but such an unexpected phenomenon would certainly have considerable bearing on the problems of weather forecasting. Recent data from Nimbus 4 have also revealed other examples of strange behaviour around the south pole. Quite large volumes of air in the upper stratosphere have been observed to warm up rapidly in only a few hours and have subsequently moved round the pole and mixed with regions of cold air. The temperature rises in these "sudden stratospheric warmings" have been as high as 20° C and their effect can be seen down to about 35 km. It is tempting and logical to speculate that the causes of all these disturbances can be traced back to the surface of the Earth. Mountain ranges such as the Andes are potential candidates, and future work will have to determine whether or not the fluctuations can be predicted easily and how much fine structure there is associated with them.

Plans for Nimbus 5 include large scale measurements of water and ice throughout the atmosphere as well as extensions and improvements of the present work. Future satellite equipment will eventually include microwave radiometers to replace the infrared types in use at present, but in the meantime detection of radiation in the far infrared will help to eliminate some of the problems of radiation absorption by clouds. The overall planning of the Nimbus programme continues to be a joint effort with members of the Goddard Space Flight Center, Maryland.

SELENOLOGY

What Happened to the Moon's H_2O?

by our Astronomy Correspondent

NOTHING much has been heard lately from the proponents of a one-time lunar hydrosphere. The debate had its heyday as a party game just before the first Moon landing, when the advocates of the water-on-the-Moon hypothesis were led with verve by J. J. Gilvarry. The hypothesis made some sense in accounting for the sinuous rilles, became esoteric when pressed into use to explain the mascons, and verged on the bizarre when the dark colour of the maria was attributed to decayed organic sediments.

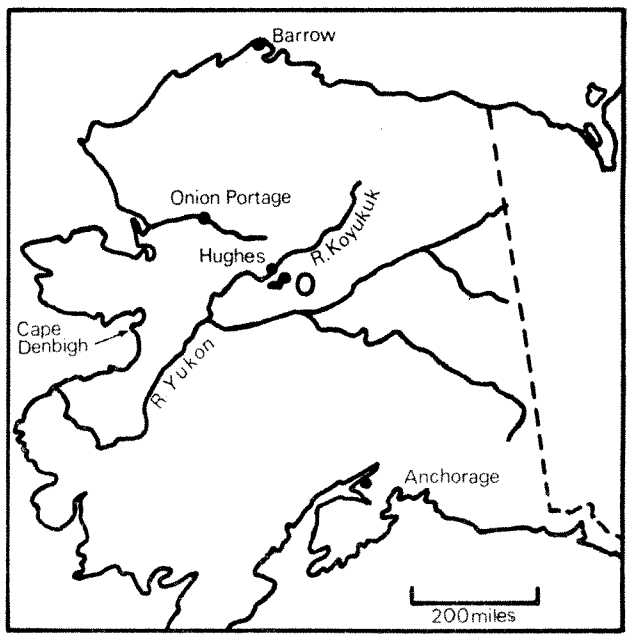
With water now notable by its absence on the Moon, even as water of hydration, the game has turned full circle. In spite of the faint hope, kept alive chiefly in NASA offices, that ancient icebanks may be present in permanently shady corners of the Moon, and that there may even be a permafrost layer, the aim now is to account for the apparent lack of water.

E. Anders of the University of Chicago has said recently that the scarcity of lead, bismuth and thallium in the lunar samples indicates that not much water can be expected, anyway (*Science*, **169**, 1309; 1970). If conditions were such as to make these easily volatilized elements scarce, then water also is unlikely to have formed in any quantity. Anders's article is founded on the view that the terrestrial planets accreted in a cooling solar nebula, with the more volatile material condensing later, so that a planet's carbon, water, lead and bismuth, for example, would be acquired as a thin crust of material with a

composition like that of carbonaceous chondrites. On the basis of the abundances of lead, bismuth and thallium, Anders estimates that the amount of this chondritic material on the Moon is equivalent to a 9 metre thick layer which would contain 370 g cm^{-2} of water corresponding to a 3·7 metre deep covering if all of it were liquid. This relatively small amount of water is an overestimate, however, Anders says, because it fails to take into account the energy released by the impacting material in the final stages of accretion. This would be enough to vaporize virtually all of the water that it contained and would also account for the absence of the volatile element sulphur in the soil collected by Apollo 11.

Anders says therefore that the case for substantial amounts of water on the Moon seems to be weak, thus begging the question of how the Earth comes to be so wet. There are several possibilities—the Moon may have accreted closer to the Sun, for example—but Anders gives weight to the view that the dynamics of accretion processes were different.

With the Apollo 15 expedition therefore unlikely to pick up evidence for a lunar hydrosphere from Hadley rille next summer, the aqueous explanation of the sinuous rilles is becoming unfashionable. In the September issue of the *Geological Society of America Bulletin*, S. A. Schumm of Colorado State University extends the fluidization hypothesis of lunar features to the rilles, explaining how the outgassing from the lunar interior that has been put forward to account for flat-floored craters may also have created other shapes (**81**, 2539; 1970). Schumm has set up a fluidized bed in which a layer of sand a few centimetres thick represents the lunar regolith and compressed air is blown through a pattern of holes beneath the bed to produce fluidization. Using linear and sinuous arrays of holes, Schumm can create structures resembling crater chains and rilles in the artificial regolith.



ARCHAEOLOGY

Sources of Obsidian

from our Geomagnetism Correspondent

THE philosophical and methodological parallels between geology and archaeology are well known; and recently both disciplines have benefited from the wider utilization of techniques once reserved for the physical sciences. The direct application of geological exploration to archaeological problems is still comparatively rare, however, probably because contact between students of the two disciplines is a matter of chance rather than a systematic attempt to discover and cooperate on common ground. How Patton and Miller (*Science*, **169**, 760; 1970) came to see their geological investigations as a solution to a problem in Alaskan archaeology will perhaps never be known, but archaeologists should be pleased that the connexion was made.

The archaeological problem is simply stated. In recent years artefacts and chippings of obsidian have been found in conjunction with chert and slate artefacts at several archaeological sites in Alaska, notably the excavations at Cape Denbigh and Onion Portage (see map). But whereas chert and slate are widely distributed in north-western Alaska, no one has ever discovered the source of the obsidian. As a result, archaeologists have had to rely on unproven hypotheses which envisage the transport of obsidian from as far away as the Aleutian Islands. Giddings (*Arctic Anthrop.*, **1**, 6; 1962), for example, even related the variations in obsidian abundance at various archaeological levels at Onion Portage to "the ebb and flow of coastal-oriented and inland-oriented cultures along the Kobuk valley". Clearly, the source of the obsidian is an important factor in the elucidation of cultural ties and trading routes in ancient Alaska.

Patton and Miller have put an end to speculation by their discovery of obsidian deposits near Hughes, Alaska, only a hundred miles or so from the Onion Portage site. The mere proximity of the source to the ancient settlements does not, of course, prove a physical connexion; but closer comparison of the excavated and indigenous obsidians goes a long way to doing so. On the descriptive level, most examples of the two obsidians compare well in colour, opacity and the absence of hydration and devitrification. And, quantitatively, use has been made of recent techniques for matching archaeological samples with bedrock deposits by chemical composition. Of particular interest in this connexion is the ratio of sodium to manganese, both elements which vary widely between obsidian flows. The ratios of sodium to manganese of the Onion Portage and Hughes obsidians are similar. The scientific and circumstantial evidence for the connexion is thus strong.

Unfortunately, Patton and Miller were unable to carry out a systematic search for evidence of ancient "mining" of the bedrock deposits. Even so, several artificially chipped obsidian flakes were found among the natural residual fragments. Furthermore, chipped fragments found on nearby hillsides and ridge tops could only have been carried there by human agency. The only question now is whether or not the Hughes site was the only source of obsidian for the ancient Alaskan communities. No further sources have been discovered, but geological associations are favourable along much of the Koyukuk and lower Yukon Rivers.

MATERIALS

Between Crystals

from a Correspondent

Two aspects of grain boundary structure came under scrutiny in Amsterdam recently. Although most useful materials occur in the form of polycrystalline aggregates, relatively little is known of the atomic structure in the vicinity of the boundaries between the various crystals. The available information was reviewed on September 22 during the meeting of the Institute of Metals.

There seem to be two distinct aspects to grain boundary structure. There is a general structure which is a direct consequence of the super-position of the periodicities of the adjacent crystals, and superimposed on this there may be imperfections, or irregularities, which can critically affect certain materials parameters. Indeed, considering the importance of dislocations within the crystal, it is tempting to draw an analogy to postulate the existence of dislocations in, or intersecting, the grain boundary.

Two approaches were adopted in the theoretical description of the general structure. Dr W. Bollman (Battelle, Geneva), from purely geometrical arguments, and Dr G. Hasson (École des Mines, St Étienne), by computing the minimum energy configuration for an assumed interatomic pairwise potential, concluded that a grain boundary of arbitrary orientation would be expected, on the atomic scale, to consist of straight sections, where the matching between the crystal lattices is good, connected by sections of poor matching.

Dr H. Mykura (Warwick University) pointed out that adjacent crystals normally bear no special crystallographic relationship to each other. Nevertheless, the observations of macroscopic facets (of good intercrystalline fit) by optical, electron and field-ion microscopy indicate that boundaries tend to be arranged in a direction such that they contain a high proportion of atoms common to both lattices (coincidence boundaries), which is clearly energetically reasonable. Precipitation of second phase particles occurs preferentially at grain boundaries containing ledges where the atomic fit is bad and at dislocations in the grain boundary.

Several contributors, using transmission electron microscopy, had observed linear defects at the grain boundary. Dr D. Dingley (University of Bristol) compared some electron micrographs with a computer simulation of the image expected from the combined strain fields of a dislocation and grain boundary, and confirmed the defects to have simple lattice burgers vectors. On the other hand Drs D. Smith (University of Oxford) and B. Loberg (Chalmers University) by studying specimens by both electron and field-ion microscopy have observed, at a grain boundary, dislocations with burgers vectors which are not simple lattice vectors of either crystal, which suggests that segments of the dislocation lie in the plane of the boundary.

Certain phenomena seem to depend sensitively on the structure of the grain boundary. For example, Dr M. Biscondi (École des Mines, St Étienne) showed that, for a given shear stress, the rate of grain boundary sliding is slower for boundaries of high coincidence than for the more disordered boundaries. Dr C. A. P. Horton (Central Electricity Research Laboratories, Leatherhead) suggested that the occurrence of grain boundary sliding and crystal deformation were closely related. Presumably, dislocations generated within the crystal can migrate to the grain boundary, and grain boundary sliding is achieved by displacement of segments of the dislocation in the plane of the grain boundary.

Grain boundaries are known to act as efficient sources and sinks of vacancies during the high temperature creep of polycrystalline materials. This behaviour cannot be explained in terms of the general equilibrium structure, and implies the existence of a self-perpetuating defect. Dr E. D. Hondros (National Physical Laboratory) showed that such vacancy sources can be rendered inactive by the adsorption of certain impurities to the grain boundary, while in other circumstances even low angle subgrain boundaries seem to act as efficient source/sinks.

There was therefore substantial evidence, supported by many other contributors, that both aspects of grain boundary structure are necessary, although the precise nature of the defects is still a subject for debate.

SOLID STATE

More and Better Devices

from a Correspondent

THE latest progress in solid state devices was the theme of a conference held at Exeter by the Institute of Physics and the Physical Society from September 15 to 18. Most contributions were concerned with semiconductors, and covered topics from materials to computer aided design.

Three contributions from the group under Dr C. Hilsum (Royal Radar Establishment, Malvern) described pioneering work on indium phosphide. Miss A. Royle described the growth of large single crystals with electron densities from 10^{14} to 10^{18} electrons/cm^3 and mobilities up to 3,000 cm^2 V^{-1} s^{-1}. Semi-insulating InP had now been made. The preparation of vapour phase grown InP layers was described by Dr B. D. Joyce, who said that they had achieved low electron densities and a mobility of 4,740 cm^2 V^{-1} s^{-1} (60,000 cm^2 V^{-1} s^{-1} at 77 K), which is the highest reported for this compound. Dr J. R. Morgan described a three level transferred electron microwave oscillator using the ultrapure InP layers. Oscillations up to 28 GHz had been observed while at 8·5 GHz a 7 per cent efficiency had been obtained. No continuous wave output had yet been realized. A broad tuning range and reasonable efficiency indicate that this three level oscillator has good prospects.

Dr G. H. Schwuttke (IBM) showed, with the aid of X-ray topograms, the propagation of dislocations in a defect free silicon wafer, as it progressed through the various stages of oxidation, epitaxy and diffusion involved in the making of an integrated circuit. He was able to correlate the electrically defective devices with the highly dislocated regions in the wafer. When the wafer is laid horizontally in the furnace instead of vertically, as is the normal practice, and very rapid changes of temperature are avoided, the number of dislocations can be reduced considerably and a device yield as high as 90 per cent is achieved. He said that 1970 was the year of large scale integration (LSI) for

such applications as solid state memories. As the emphasis in the industry was now on cost and thus on yield, and not the speed of operation, interdisciplinary activity was essential to remove the "art" from the processing and establish a sound process control. He expected to see a revolution from manufacturing research.

Dr G. E. Moore (Intel Corp.), surveying semiconductor memory, said that considerable progress had been made, and integrated memory devices were now cost competitive with conventional stores (for example, the magnetic core store) and also offered increased performance. As the yield increases with decreasing area, considerable effort is being made to increase the packing density by research into the metal semiconductor transistor technology. He also mentioned dielectric storage devices, ovonic switches and magnetic bubbles as other promising approaches for memory systems. Memory development as a whole is in a state of flux, and manufacturers are in a dilemma as to which line of research to pursue. Several contributions on dielectric storage devices indicated that these are still far from being a practical memory.

Magnetic bubbles, small stable regions of reverse magnetization in a highly anisotropic ferrimagnetic sheet, were described by Dr F. C. Rossol (Bell Telephone Laboratories). A telephone dialler has been made using the bubbles and in the future a bubble store could replace the present disk files in a computer. A store containing 10^7 bits per cubic inch at a cost of "milli cents" per bit was projected.

Mr D. Baker (the Post Office), reviewing microwave transistor technology, emphasized the need for narrow emitter stripes and base widths and reduced base resistances. He anticipated that electron beam techniques for resist exposure will be essential for fine geometrical structures. More than ten contributions were concerned with transistor design and performance indicating a continuing and lively interest in bipolar structures.

Dr P. R. Selway (Standard Telephone Laboratories) gave the details of an aluminium gallium arsenide double-heterostructure injection laser. This is efficient enough for continuous operation at room temperature, and this opens up the feasibility of an optical transmission system.

Dr C. Sandbank (Standard Telephone Laboratories) explained the addressing on a moving high field domain in CdS. It is possible to initiate electroluminescence from a domain, and, by scanning, Sandbank ultimately hopes to obtain a display with the resolution of a television picture.

METALLURGY

Recovery and Recrystallization

from a Correspondent

STEEL was a dominant theme at the discussion of recovery and recrystallization held in London on October 2 under the auspices of the Institution of Metallurgists. The plastic behaviour of rimming steels, vacuum-melted iron of high purity, as well as of aluminium has been examined by Dr G. M. Sellars (University of Sheffield) by means of "hot" torsion tests. He showed that in the usual industrial hot-working conditions the critical strains at which recrystallization set in were generally exceeded, particularly in rolling of steels. It occurred discontinuously, in "spurts" separated by periods of intense hardening of the structure, during deformation. Recovery and recrystallization obliterated the structural changes so effectively that it was common to find equiaxed rather than elongated grains in steels strained in hot-rolling passes by 300 per cent. The size of subgrains seemed to be a measure of the strength of the material at all times; the kinetics of their migration, generation and annihilation were, however, still obscure in detail.

The less "drastic", secondary type of recrystallization, essentially grain growth controlled by the grain interface energy, had been studied by Dr T. Healey (Nuclear Laboratories, Berkeley) in niobium-stabilized 25/25 Ni/Cr steels containing 0·017–0·043 per cent (by weight) of carbon. A theoretical interpretation of the observations based on the Wagner–Lifshits concepts of particle coarsening, and embodying Zener's model of grain-growth inhibition by precipitate particles, developed by him, accounted reasonably well for the observations, particularly for the occurrence of an incubation time $t = A \exp(E/kT)$, in which A increased with carbon content in the range of temperatures used, that is, 920°–990° C. E was independent of the carbon concentration; its value, 5·5 eV, was unexpectedly high, lying well above the activation energy of vanadium diffusion (3·2 eV) in the material. Its precise significance was still a matter for speculation.

Dr I. D. McIvor (British Steel Corporation) illustrated with two examples what he considered to be a general principle, namely, that fine precipitates with dimensions less than about 200 Å, coherent with the matrix, tended to inhibit recrystallization and subboundary displacements. Coarser ones, such as vanadium carbides or nitrides which had "grown", were, however, found to be effective recrystallization nuclei. Again, he considered the resistance of the material to plastic deformation to be largely a function of subgrain size; a Hall–Petch relation seemed to hold.

A different aspect of hot deformation was discussed by Dr W. B. Hutchinson (University of Birmingham). He pointed to the shortcomings of the pole-figure representation of rolling textures. The former were two-dimensional, while crystals had three rotational degrees of freedom. A more informative description of textures consisted of a series of "intensity" maps, drawn on standard stereographic triangles, each referring to a section through the sheet, each inclined by a different angle in the range 0°–90° to the rolling plane. Such maps could be made and used with ease, once the computer program for drawing them was set up.

Dr E. D. Hondros (National Physical Laboratory) showed that in metal sheet which was thin compared with the diameter of the grains—that is, it contains "pancake" grains—the difference between the surface energies of adjacent grains was the chief driving force for boundary migration, provided that "Zener drag" due to impurity absorption into the boundary was absent. Chemisorption provided means for modifying surface energy anisotropy. He demonstrated this with measurements on (3 per cent) silicon iron sheet, in which grain growth had taken place in the absence of chemisorbed oxygen (partial pressure $2{\cdot}5 \times 10^{-27}$ atm.), and in the presence of chemisorbed oxygen (partial pressure 10^{-16} atm.) respectively. In the latter case the desirable (100) texture prevailed over the customary (110) orientation. Sulphur, nitrogen and

other gases were also effective in modifying surface energy anisotropy.

Professor P. Feltham (Brunel University) showed that stress relaxation provided a method for studying recovery at low temperatures, for example, at 20 K in nickel. In principle a single relaxation curve sometimes sufficed for determination of the magnitude of the energy barrier to dislocation movement. He illustrated this for the case of the Peierls barrier in α-iron. The method was potentially most useful in the design of alloys, but these potentialities had not as yet been generally recognized, he said.

BIRDS

Magnetism of Navigation

from our Animal Behaviour Correspondent

THE way in which migrating birds find their way continues to be a puzzle to zoologists. Until quite recently, however, it was thought possible to discount at least one theory—that birds made use of the Earth's magnetic field for navigational purposes. Experiments in which magnets were attached to the wings of homing pigeons and found not to interfere with their homing ability at all seemed to show that they could not possibly be using magnetism. Then, in a series of articles, W. Wiltschko (*Z. Tierpsychol.*, **25**, 537; 1968) claimed that European robins could be made to reorient their migratory activity with respect to a static artificial magnetic field, putting the magnetism theory once more firmly in the running.

S. T. Emlen (*Anim. Behav.*, **18**, 215; 1970), at Cornell University, on the other hand, has recently reported his failure to confirm these results with indigo buntings (*Passerina cyanea*). In the absence of visual cues, these birds seemed totally disoriented, and they also failed to learn that they could avoid a brief electric shock by responding to a change in the direction of the magnetic field in a classical conditioning experiment.

These negative results do not, of course, rule out the possibility that indigo buntings may be able to use magnetic cues, and should be viewed in the light of Wiltschko's claim that his birds only responded to changes in a magnetic field when the strength of the artificial field closely corresponded to that of the Earth's field. The robins did not orient to stronger fields. This intriguing problem is still open.

CELLULOLYTIC ACTIVITY

Municipal Refuse Composting

from our Microbiology Correspondent

ONE of the major limitations to the effectiveness of composting solid waste is the incomplete degradation of cellulosic materials, or the long period required for its removal. The results of a research programme carried out at the US Department of Health, Education and Welfare and East Tennessee State University on cellulolytic activity in municipal refuse composts are therefore interesting and timely. Stutzenberger and his colleagues (*Canad. J. Microbiol.*, **16**, 553; 1970) have studied the factors effecting cellulose decomposition in refuse dumps and defined precisely the kinetics of the process.

Municipal solid waste, after being ground, was mixed with concentrated sewage sludge and piled into low ridges or windrows. The windrows, about 9 feet wide, 3 feet high and 150 to 250 feet long, were sampled during a seven week composting period for cellulolytic activity. Measurements of temperature indicated the course of the composting process. Thus the windrow heated up at a linear rate and usually exceeded 60° C by the end of the first week. A temperature gradient of 10° to 15° was quickly established in the windrow and maximum heat was developed in the middle of the fermenting refuse. The peak temperatures held for about two weeks and thereafter the windrows cooled gradually but even after the end of the experimental period the temperature was about 50° C.

Cellulase activity was measured using soluble carboxymethyl cellulose as the substrate and, although the resulting data clearly indicated the progress of cellulolysis, it seems a pity that a cellulosic substrate closer in physico-chemical properties to that encountered in solid waste was not used. Nevertheless, a consistent temperature optimum of 65° to 70° C for the cellulase activity of compost extracts was observed and this optimum was independent of the age of the windrow. Temperatures considerably greater than 60° C often develop in composts, and Stutzenberger accordingly tested the activity of compost extracts at 75° C. Although activity declined 70 per cent within three hours, the residual cellulase remained very stable for up to twenty-four hours at the hotter temperature. Experiments designed to follow the selection of thermostable cellulase producers were not carried out, but it is likely that such development would occur within a natural microflora. Specific cellulase activity, however, increased exponentially during the seven week composting period, while the total cellulase content decreased by half. The final product was described as having the appearance, texture and odour of soil.

Of the microorganisms responsible for cellulose decomposition in the windrow composts, *Aspergillus fumigatus* and a *Bacillus* species grew at 45°–50° C, and a third, not surprisingly an actinomycete, was more thermophilous and grew at 55°–60° C. The crucial question now is: what limits the extent of cellulose decomposition? Heat denaturation of the enzymes and product inhibition do not seem to be implicated to any large extent. The cause of compost termination is much more likely to be substrate heterogeneity, a condition which is also responsible for the decline of glucose production by enzymatic treatment of wood cellulose (*Nature*, **218**, 320; 1968), and the complexing of cellulose with other materials, such as lignin, which blocks its hydrolysis. The 40 per cent of undegraded cellulose remaining after composting could be reduced by more extensive physical and/or chemical pretreatment of the raw waste or by seeding the partially degraded material with lignicolous microbes. Alternatively, it might be used directly as a substrate in commercial mushroom farming as Block suggested (*Appl. Microbiol.*, **13**, 5; 1965).

SENSORY PATHWAYS

Active and Passive

from our Experimental Psychology Correspondent

FOR several generations the large tracts of fibres which ascend to the brain in the dorsal columns of the spinal

cord have been thought to convey information necessary for proprioception, and for fine tactile discriminations of stimulus location, separation, size and texture. But "One must now question the validity of the generally accepted view of dorsal column function". This is the opening of an article by P. D. Wall (*Brain*, **93**, 505; 1970) which critically attacks the view that has been held with great conviction since the first fumblings towards neurological localization of function in the nineteenth century.

For some time Wall has been ransacking the scattered literature on this problem. Curiously, all the available evidence seems to contradict the universal view, but the idea has been so thoroughly accepted that mere evidence has not been sufficient to displace it.

Relevant data are mostly of two kinds; from clinical observations, and from experiments on dorsal column section, mostly in monkeys, which have been followed by behavioural testing. In ten types of experiment reviewed by Wall, section of the columns was followed by no deterioration of any of the faculties that should have been affected according to the accepted view. Operated animals were still able to perform discriminations of weight, vibration, roughness and stimulus location just as well as normal animals. Rather than challenge the classical notion, however, investigators confronted by such embarrassing findings preferred to suppose that although the discriminations in question were normally accomplished on the basis of information ascending through the dorsal columns, in the operated animals the information acquired by other routes was sufficient for the tasks. This leads to the puzzling conclusion that the dorsal columns, which in man comprise about 27 per cent, and in the rhesus monkey about 23 per cent, of the entire cross-sectional area of the cord (compared with 1·5 per cent in teleosts), have no function other than to transmit information that can perfectly well be handled by other pathways.

Wall has supplemented his review with two experiments of his own. In one, rats had all the fibre tracts in the cord except the dorsal columns severed in the lower thoracic region. These animals never responded with the front half of their body to any stimulus applied to the hind legs, although single limb reflexes were intact, and the dorsal column fibres were found by electrophysiological measurements to be conducting. In the second experiment rats without dorsal columns, but with the rest of the cord intact, responded quite normally by arousal, startle and several other measures to stimuli applied to the back legs. But the frequency with which the operated rats oriented towards the location of the stimulus in order to explore the area was decreased in comparison with normals.

The retention of discriminative capacities in clinical cases and experimental animals, coupled with a rather more subtle deficit (noted in some reports) of a lack of ability to perform skilled exploratory movements, has stimulated Wall to propose a new idea of dorsal column function. He speculates that these tracts, enormously developed in higher mammals, act to initiate movements to explore the external environment, and transmit sensory information resulting from such exploration. This function is quite different from discrimination of stimuli that simply impinge on the surface of the body. Such passive sensory experience is in any case rather rare except in neurological examinations and psychological experiments.

TRANSFER RNA

Are Differences Significant?

from our Cell Biology Correspondent

In 1964 Sueoka and Kano-Sueko reported that during the infection of *E. coli* by phage T2 a leucyl-tRNA of the host cell is modified. Since then the idea that the amount and activity of tRNAs or their aminoacyl synthetases may be a limiting factor in the translation of messenger RNAs and affect the regulation of protein synthesis has been widely discussed. Direct evidence for such regulation is hard to come by, but it has been variously claimed that changes in the patterns of aminoacyl-tRNAs accompany at least some cases of cellular differentiation, bacterial sporulation, phage infection and virus infection. Furthermore, differences in the amounts or activities of tRNAs and their charging enzymes have also been reported between identical cells growing in different media or environmental conditions. This last observation means, of course, that comparisons of the aminoacyl-tRNAs in cells which have been cultivated for long periods need to be interpreted with great caution.

Gallo and Pestka (*J. Mol. Biol.*, **52**, 195; 1970), who have just reported an analysis of the aminoacyl-tRNAs in normal and leukaemic human lymphoblasts, are clearly well aware of the pitfalls of such analyses. To minimize spurious differences they studied newly established lines of lymphoblasts derived from a normal person and a person with acute lymphoblastic leukaemia. Furthermore, they grew the cells for the same generation times in identical media and collected them at the peak of the log phase of growth. In both the normal and the leukaemic lymphoblasts there are at least fifty-six tRNA species, and not surprisingly Gallo and Pestka detected very few differences between most of these molecules in the two types of cell. Reverse-phase partition column chromatography revealed only small but apparently reproducible differences in the leucyl, seryl, threonyl and prolyl-tRNAs, and more pronounced differences between the tyrosyl and glutaminyl-tRNAs.

The leukaemic cells apparently lack one of the three species of tyrosyl-tRNAs present in the normal cells, and the relative amounts of the two species common to both types of cell differ. The differences in the glutaminyl-tRNAs seem to reflect differences in the charging enzymes rather than differences in the tRNAs themselves. After charging the glutaminyl-tRNAs of both normal and leukaemic cells with the aminoacyl synthetases from normal cells, three species can be detected. On the other hand, after charging with the enzymes from leukaemic cells, only two species of glutaminyl-tRNAs can be resolved. Human leukaemic lymphoblasts may therefore lack a glutaminyl-tRNA synthetase which is present in normal cells. Until other lines of normal and leukaemic cells have been compared, however, the significance of these results is obscure; they may only reflect a normal variation among lymphoblasts rather than differences resulting from leukaemia.

In the same issue of the *Journal of Molecular Biology* (*ibid.*, 247), Morris, Wagner and Roizman report their failure to confirm earlier claims that herpes simplex virus specifies arginyl and seryl-tRNA during productive infections of HEp-2 cells. Morris *et al.* find no

differences between the tRNAs for these two amino-acids in infected and uninfected cells and purified arginyl and seryl-tRNAs from infected cells fail to hybridize with herpes simplex DNA. There is a remote possibility that the virus specifies tRNAs specific for derivatives of serine and arginine, but it seems more likely that the virus uses only cellular tRNAs during its replication.

ENZYMES

Synthetases Analysed

from our Molecular Biology Correspondent

"NUCLEIC acid-protein interactions" is an incantation which is just now widely held to possess talismanic powers. A particularly desirable case is that of the transfer enzymes, not least because so much is now known about the structure and reactions of their substrates. There is hope that the crystallographic structures of one or two tRNA species will in time be solved, and the possibility of co-crystallizing the transfer enzymes with their tRNA cannot be far from the crystallographers' minds.

A number of transfer enzymes from *E. coli* have been prepared in a highly pure state, and it comes as something of a surprise that within this group of molecules, which differ so subtly in specificity, there should be considerable structural differences. The latest study, for example, on valyl and leucyl-tRNA synthetases (Berthelot and Yaniv, *Europ. J. Biochem.*, **16**, 123; 1970) bears out early reports that these enzymes consist of single polypeptide chains with the unusually high molecular weight of 110,000. Binding plots show that each chain possesses only one amino-acid binding site, and measurement of the stoichiometry of the complex with the amino-acid and AMP gives the same answer. Other synthetases reported to contain only one chain are those for lysyl-tRNA, with 85,000 molecular weight, and leucyl-tRNA, with 100,000. Several others, however, are dimers or tetramers, and these all appear to have subunit molecular weights close to 50,000 (or at least 40,000, it not being at this juncture clear whether —no offence intended—such a difference is significant).

One of this group is methionyl-tRNA synthetase, which seems to exist in the cell as a tetramer, but Cassio and Waller reported some time ago that it is dissociated irreversibly in the presence of a cytoplasmic factor into a fully active dimer. Methionyl-tRNA synthetase has now been taken in hand by Bruton and Hartley (*J. Mol. Biol.*, **52**, 165; 1970), who have applied to its study every artifice of the protein chemist's craft. Working with the dimeric form, they have used equilibrium dialysis to construct binding plots for the amino-acid and for ATP, and find two binding sites per molecule, or one per chain. Binding of methionyl-tRNA, and also of the species that will accept formylmethionine, were measured by the accompanying changes in protein fluorescence which again led to two sites with identical intrinsic binding constants, that is to say with no mutual interaction.

By radioactive labelling of the α-amino group and proteolysis, an N-terminal peptide could be isolated and sequenced. The presence of a unique tetrapeptide sequence from both the dimeric and tetrameric enzyme, taken together with identical binding constants of the two sites in respect of the amino-acid and two tRNA species, makes it overwhelmingly likely that the enzyme in fact consists of identical chains.

Bruton and Hartley have also begun an exploration of the enzymatically essential residues. In the first place the free dimer has ten accessible cysteines, eight of which react rapidly with a thiol reagent (and with iodoacetamide). The reaction of the other two is accompanied by dissociation into monomers and inactivation, both effects being reversed when the blocking group is stripped off. (Similar essential thiols have also been reported for other synthetases.) Finally, Bruton and Hartley have brought off an active site labelling reaction, in which a reactive function, containing a nitrophenyl group, is attached to the α-amino end of methionyl-tRNA. This finds a nearby lysine, with which to react, and after enzymatic digestion, fragments containing the methionyl-tRNA were isolated. The sequence of an octapeptide containing the central lysine is given.

This is an admirable beginning to a complete characterization of the system. The relation between the dimer and the tetramer and the significance of the latter remains obscure. It is interesting to note that Rouget and Chapeville (*Europ. J. Biochem.*, **14**, 498; 1970) also found a cytoplasmic factor which modified a synthetase, in this case, however, the leucyl-tRNA enzyme, which is a 100,000 single chain. The factor was found to promote the interconversion between an active form, and one which, though it binds leucine tRNA is unable to transfer the amino-acid to it; its other characteristic activity, of exchanging pyrophosphate against bound ATP, remains intact, but with impaired specificity. There is perhaps more to the regulation of transfer enzyme function than is yet apparent.

CYCLIC AMP

Involved with Hormones

from a Correspondent

WIDESPREAD interest in cyclic adenosine 3′,5′-monophosphate, and in the enzyme systems which produce and destroy this compound, was clearly indicated by the size of the audience which assembled, during a meeting of the Biochemical Society in the University of Dundee, for a colloquium on adenyl cyclase and cyclic AMP on September 24 and 25. The first contribution was from Professor J. Kilpatrick and Dr P. W. Major (University of Sheffield), who outlined the development of interest in cyclic AMP as the mediator of many hormonally controlled processes. The list is now so extensive that one should ask which processes are not controlled or influenced by cyclic AMP rather than which are so controlled. Their report was illustrated with references to their own work on the interaction of luteinizing hormone with rabbit ovary adenyl cyclase. Dr D. G. Grahame-Smith (St Mary's Hospital, London) discussed the evidence which implicates cyclic AMP as the mediator of the effect of adrenocorticotropic hormone on the adrenal cortex, in respect of its steroidogenic and tissue maintenance properties. He emphasized the lack of understanding of the way in which cyclic AMP acts in the adrenal cortex, but mentioned studies with protein synthesis inhibitors which suggest that *de novo* synthesis of protein may be involved.

Dr J. I. Davies (University of Wales, Bangor) was concerned with the factors which control the intracellular concentration of cyclic AMP. Assuming these to be the enzymes adenyl cyclase (with or without hormonal stimulation) and cyclic AMP phosphodiesterase, he presented a theoretical kinetic relationship in the form of an equation which could be used to predict tissue levels of cyclic AMP. He showed most clearly that experimental results from many laboratories were compatible with his calculations.

Dr D. A. Stansfield and Mr D. J. Franks (University of Dundee) have approached the study of the properties of adenyl cyclase by attempting to separate luteal adenyl cyclase from the complex ATP hydrolysing system which is also present in plasma membrane fractions, and which competes very successfully with adenyl cyclase for the available substrate (ATP) in *in vitro* incubations. They emphasized the lack of understanding of the way in which fluoride ions activate adenyl cyclase and inhibit the "ATPase" and suggested that fluoride polyanions are responsible for some of the effects which vary with fluoride concentration. Studies with an ATP analogue, β,γ-methylene ATP, were also described.

The lack of convenient and accurate assay methods for cyclic AMP was underlined during the discussion, and by the presentation of two methods for determination of cyclic AMP in later sessions of the meeting. A method which seems to have very great potential was described by B. L. Brown, R. P. Ekins and W. Tampion (London); in this saturation analysis study a specific cyclic AMP binding protein from bovine adrenal cortex was used in combination with charcoal adsorption of unbound nucleotides. Several other communications dealt with kinetic studies of cyclic AMP phosphodiesterase. A. R. Sommerville, M-L. Rabouhans, A. A. Smith, I. F. Skidmore and S. T. Hindley (Macclesfield) have explored the kinetics of this enzyme at substrate levels usually used in *in vitro* assays (about 0·5 mM) and at very low substrate levels. The Lineweaver-Burk plots they obtained suggested the presence of two enzymes, with very different K_M values.

Discussion also brought out the unreliability of implicating cyclic AMP in a system solely on the grounds that methyl xanthines had an effect on the system. Caffeine and theophylline can, apparently, have effects other than the inhibition of cyclic AMP phosphodiesterase.

SPOROPOLLENIN

Interest in Exine

from a Correspondent

THE unifying influence of sporopollenin was clear at Imperial College, London, on September 23 to 25. Geologists, organic chemists and many others gathered for a symposium on the most chemically inert substance produced by plants. Sporopollenin forms the outer coat of pollen grains and spores of higher plants, and there is interest in its composition, its formation in living plants and its survival in ancient sediments.

Professor J. Heslop-Harrison (London) reported that centrifugation and treatment with colchicine at different stages of pollen formation interrupt the normal pattern of sporopollenin deposition, giving new insight into the controlling mechanism. In his experiments with *Lilium* fragments of microspore cytoplasm, lying within the pollen sac, but lacking a nucleus as a result of post-meiotic centrifugation, nevertheless had a normal sculptured exine deposited on their surface; while similar fragments derived from (diploid) tapetal cells received a layer of sporopollenin, but without the characteristic sculpturing pattern. He suggested that although most sporopollenin precursors must be supplied from the tapetum, these results are consistent with the view that the pattern is dictated by the cytoplasm of the haploid cell; and further, that this cytoplasm is already "programmed" (probably from the time of the first prophase of the meiotic division) for a pattern which is independent of the presence of a nucleus. The sporopollenin precursors, regarded by Dr G. Shaw (University of Bradford) and his students as carotenoids, seem to be polymerized *in situ* on the developing exine; the role of enzymes in this polymerization remains uncertain and Heslop-Harrison suggested that at least the final stages in the assembly of sporopollenin may be non-enzymatic.

The biological degradation of sporopollenin offers as many problems as its synthesis. Spores and pollen exposed to microbial activity in controlled natural soil environments by Dr A. J. Havinga (Wageningen, Holland), and fossil spore exines occurring in sedimentary rocks examined by Dr W. C. Elsik (Houston), all show evidence of degradation in which both fungi and bacteria seem to be involved. The role of soil fauna may be considerable, but this is less well documented. Sporopollenin is much more sensitive to raised temperatures and pressure for prolonged periods (diagenesis and, eventually, metamorphism) than mineral constituents of sedimentary rocks. Computer analysis of an extensive study of fossil sporopollenin in a wide range of lithologies subjected to different patterns of diagenesis, conducted by Drs M. J. Correia and G. Peniguel (Pay, France), offers a basis for evaluating the role of the many factors involved in the diagenetic process.

Drs J. Brooks (Sunbury) and Shaw emphasized the significance of the similarity of physico-chemical characteristics (infrared absorption spectrum, pyrolysis gas chromatography) of sporopollenin from living plants to those of the insoluble organic residues of ancient ($3{\cdot}7 \times 10^9$ year old) sediments and even of carbonaceous meteorites. Shaw advocated extending the term sporopollenin without qualification to all these substances, regarding their presence as evidence of life-activity, of both terrestrial and extraterrestrial source. Several botanists urged a narrower concept of sporopollenin, and would restrict its use to material demonstrably derived from the spores of higher plants.

In spite of the emphasis placed by chemists on the unity of sporopollenins from various sources, minor differences in composition may be clues of value in interpreting the history of fossil material. The use of ultraviolet fluorescence microscopy, described by Dr Van Gijzel (Nijmegen), of the new technique of cathodoluminescence on the scanning electron microscope, described by Drs M. Muir and P. Grant (London), and of centrifugation of fossil assemblages on a density gradient, described by Drs W. Chaloner and G. Orbell (University College, London), were all advocated as means of detecting small compositional differences, reflecting the origin and post-depositional history of fossil sporopollenin.

Glutamate and γ-Aminobutyric Acid in Brain

by
K. KRNJEVIĆ
Department of Research in Anaesthesia,
McGill University

Evidence is accumulating that, in the brain, the amino-acids L-glutamate and γ-aminobutyric acid (GABA) are essential agents of communication and not just elements of an alternate metabolic pathway, as was generally believed for some years.

It has long been known that slices of brain can metabolize L-glutamate[1] transforming it, in a process which involves transamination and oxidation, to α-oxoglutarate (Fig. 1)[1,2]. The addition of glutamate thus increases the oxygen consumption of the brain. Slices of cerebral cortex can absorb large amounts of glutamate from incubating fluid, and a great deal of K^+ is taken up at the same time[3–6]. Although glutamate stimulates cerebral metabolism, glucose is the principal source of energy utilized by the brain: glutamate therefore seemed to serve some unknown function in the transport of K^+ (ref. 4).

Like other nerve cells, cerebral neurones are normally rich in K^+ and poor in Na^+. But the inward flux of Na^+ and outward flux of K^+ associated with depolarization and spike activity tend to reduce the difference between the internal and external concentrations of these ions. The normal steep gradients of concentration across the membrane are restored by an Na-K pump, which, through the expenditure of energy, can extrude Na^+ from the cell in exchange for external K^+ (refs. 7, 8). The high content of K^+ in the brain is thus a function of the state of polarization of the cells and can only be maintained by metabolism. It is therefore significant that glutamate has a powerful depolarizing action on cerebral neurones.

Excitation by Glutamate

The excitatory action of glutamate was first apparent in Hayashi's experiments[9] on the cerebral cortex. The effect is so strong and so rapid that it may not be recognized as excitation. Gross applications of glutamate to the brain surface give rise to "spreading depression"—a slowly moving wave of intense neuronal depolarization and inactivation—and so abolish all spontaneous and evoked activity[10].

Excitation is clearest when glutamate is released within the brain in minute amounts (10^{-13} equiv/s), by iontophoresis from a micropipette (Fig. 2*A* and *B*)[11,12]. The evoked discharge, which is typically rapid in onset and stops sharply when the release ends, is associated with depolarization of the neuronal membrane[11,13,14]. Most central neurones have this excitatory effect, but other cells (neuroglia) are not depolarized by glutamate[14]. The fact that neurones in spinal ganglia are also not depolarized by glutamate[15] suggests that the sensitivity to glutamate depends on the presence of synaptic contacts.

To excite neurones, glutamate must somehow trigger the entry of Na^+. Like acetylcholine at the muscle endplate, it may do this by increasing the general permeability to cations. Alternatively, glutamate may activate a specific Na^+-carrier, similar to that which generates the nerve action potential[16]. There is some evidence against this, however. Tetrodotoxin, a specific inactivator of the Na^+-carrier[17], does not block very effectively the influx of Na^+ caused by glutamate[18].

Both glutamate and Na^+ are perhaps transported by the same carrier (Fig. 3), as in the mechanism suggested for amino-acid uptake in the gut[19]. In such a scheme, glutamate could be removed from its site of action without the need for a special glutamate pump, the energy being supplied by the electrochemical inward gradient of Na^+, maintained by the Na-K pump. It is assumed that the common carrier has separate sites for combination with

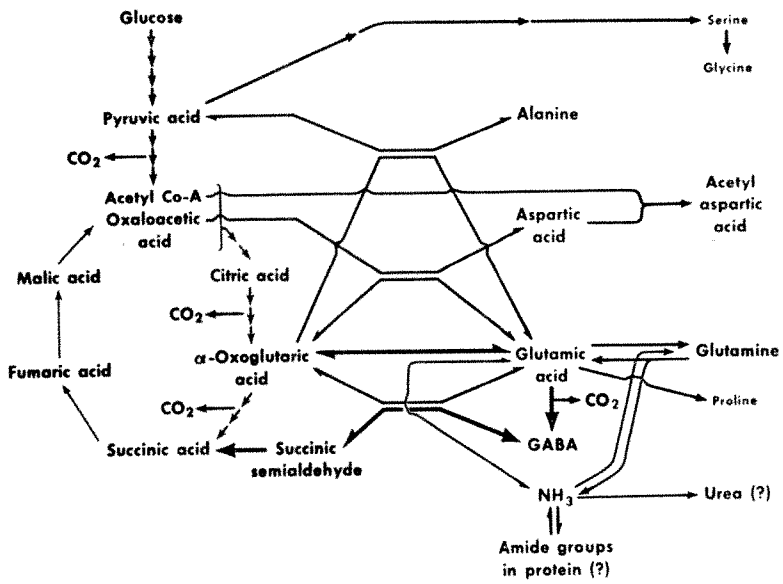


Fig. 1. Glutamate, GABA, and glucose metabolism in the brain (from ref. 90).

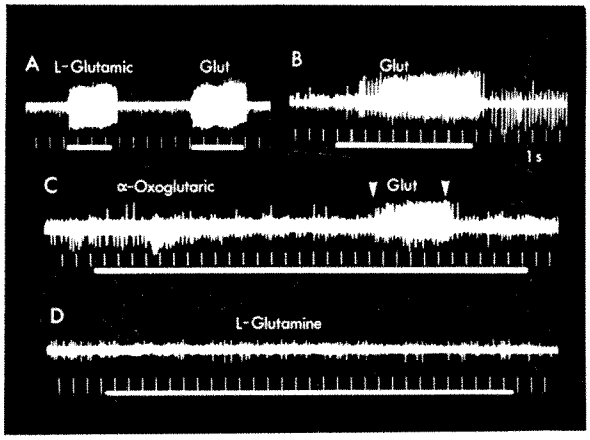

Fig. 2. Excitatory action of L-glutamate applied to cortical neurones by microiontophoresis (60–70 nA), at times indicated by white lines below oscilloscope traces. (*C*) α-Oxoglutarate (170 nA) had no effect and did not prevent action of glutamate applied between arrows. (*D*) Application of L-glutamine (100 nA) for a long time was also ineffective.

Na^+ and glutamate; that through a conformational change in the carrier, the affinity for Na^+ is much increased by the attachment of glutamate; and that the affinity for glutamate is itself a function of the Na^+ concentration. Thus external glutamate would promote the entry of Na^+, while being itself transported into the Na^+-poor cytoplasm, and the membrane would depolarize if this influx of Na cations exceeds that of glutamate anions. This hypothesis is given some support by the marked dependence of glutamate uptake on the presence of external Na^+ (ref. 5).

Glutamate excites so much more powerfully than much stronger chelators that its action cannot be ascribed principally to the binding of Ca^{2+} (refs. 12, 20).

Glutamate and Accumulation of Potassium Ions

Whatever its precise mechanism, the depolarizing effect of glutamate is probably caused by an influx of Na^+, and it should be followed by an efflux of K^+. What, then, is the reason for the observed increase in the K^+ content of brain slices?

An important additional observation is that glutamate causes a comparable increase in water content[4,21]. Because the cells swell, the internal concentration of K^+ remains approximately constant[21]. The complete sequence of events has been described by Harvey and McIlwain[8]. Within a minute of adding glutamate to brain slices, there is an increase in the Na^+ and a decrease in the K^+ contents of the "non-inulin" compartment (a useful index of the volume of intracellular water because bulky inulin remains outside the cells). At this stage there is no detectable movement of water. Thus the initial fluxes of Na^+ (in) and K^+ (out) can be explained as a direct consequence of the depolarizing action of glutamate.

In the next phase, the influx of Na^+ continues, but is accompanied by an influx of K^+, and there is an increase in intracellular water. These phenomena presumably follow the activation of the Na-K pump by the rise in internal Na^+. This active uptake of K^+ leads to a depletion of the high-energy phosphate compounds that provide the immediate energy requirements of the Na-K pump[22]. In spite of the continued rapid influx of Na^+ and K^+, a significant increase in internal osmolarity is prevented by the inflow of water. Glutamate causes similar changes in the Na^+, K^+ and water content of the isolated retina[4,23].

Glutamate as a Transmitter

The brain contains plenty of glutamate (about 10 μmole/g), more than its content of any other amino-acid[24,25]. This fact has perhaps militated against the idea that glutamate might be a transmitter—that is, a substance released by nerve endings at synaptic contacts to excite or inhibit other neurones. Neurotransmitters are often believed to be very scarce substances, difficult to extract or identify, and probably highly labile. Glutamate is the reverse of all these. Not only is it very abundant, but it is highly active in brain metabolism: if radioactive pyruvate, acetate or glucose is injected into an animal, labelled carbon is very rapidly incorporated into cerebral glutamate (Fig. 4)[26–31].

The general abundance of glutamate is not sufficient evidence of a transmitter function. The presence of adequate amounts of glutamate in excitatory nerve endings would be more significant. In an attempt to throw some light on this point, Whittaker and I[32] examined the excitatory properties of the contents of cortical nerve endings. Gray and Whittaker[33] had shown that nerve endings separate from nerve fibres when the cortex is homogenized and then centrifuged in a suitable density gradient. Suspensions of such isolated nerve endings were inserted into micropipettes and their contents released close to nerve cells in the cortex. Definite excitatory effects were observed, which could be ascribed to the glutamate content of the endings measured in separate experiments by Mangan and Whittaker[34]. Enough glutamate must therefore be present, at least in some nerve endings, for a significant synaptic action. Cerebral glutamate in general seems to be widely distributed, presumably in neuronal cytoplasm[35–37], but intracellular glutamate probably does not directly influence neuronal activity: unlike extracellular applications, intracellular injections of glutamate do not cause excitation[38].

The glutamate sequestered in isolated nerve endings forms *in situ* an active and readily accessible "pool". For example, it is rapidly labelled by systemic injections of

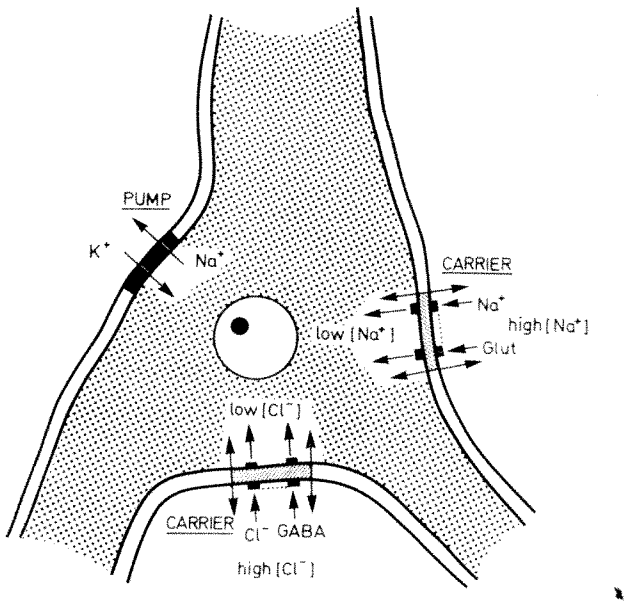

Fig. 3. Hypothetical model of glutamate and GABA carriers. Combination of glutamate with carrier on surface of cell promotes entry of Na^+, while combination of GABA with its carrier accelerates movement of Cl^- (see text).

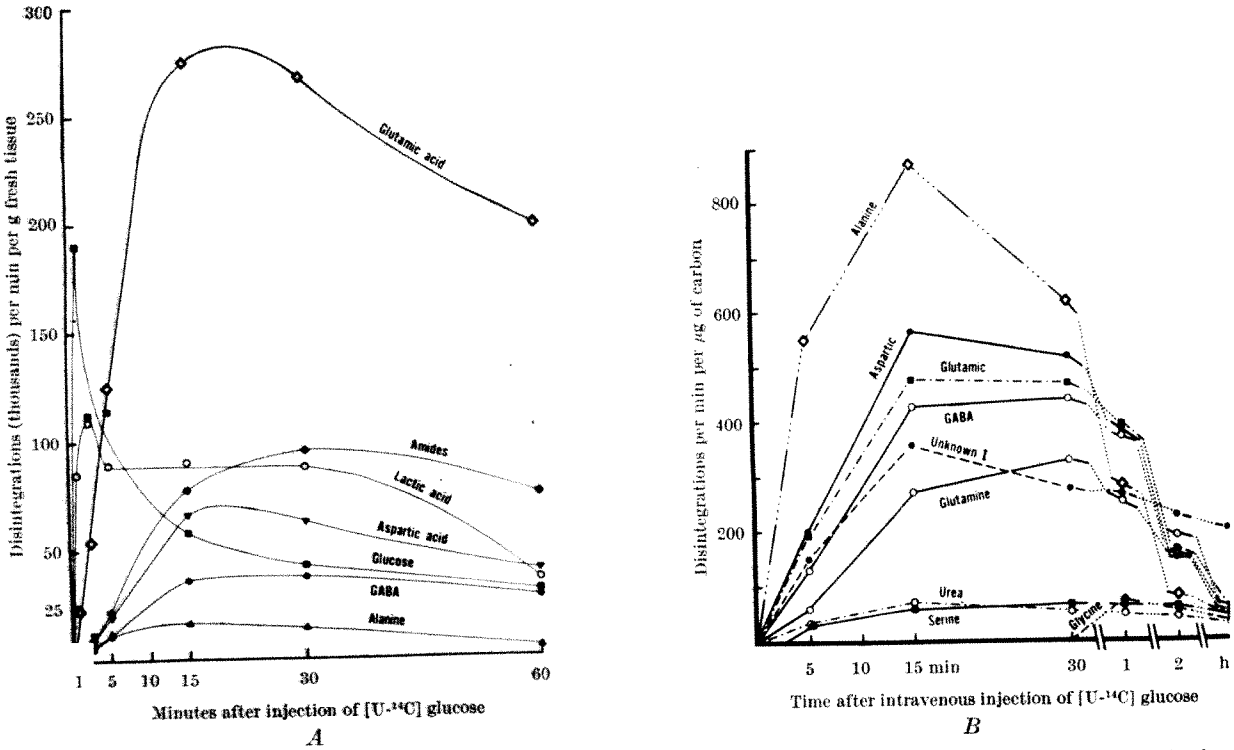

Fig. 4. Radioactive labelling of glutamate, GABA and other amino-acids in rat brain after intravenous injection of U-^{14}C-glucose. (*A*) Total radioactivity, (*B*) specific activity of ninhydrin-positive material (from ref. 31).

radioactive glucose[39]. And much of the uptake of glutamate into cortical slices finds its way into nerve endings[37]. By efficient synthesis and recapture, nerve endings evidently could supply the variable quantities of glutamate needed for synaptic release, without maintaining a large store.

Further evidence is required to confirm a possible transmitter function of glutamate: for example, that glutamate is released by excitatory nerve fibres. All that is known so far is that glutamate is continually being released at the surface of the brain[40]. The rate of release varies with cortical electrical activity, and it can be increased by stimulating the brain stem reticular formation. According to recent experiments[41], suspensions of isolated nerve endings selectively release glutamate and aspartate when they are stimulated electrically or with solutions rich in K^+. A serious problem is that re-uptake must prevent the escape of all but a small fraction of any glutamate released. If the process of uptake is driven by the Na^+ gradient, it will be difficult to block without abolishing all neuronal activity—except possibly by competitive inhibition.

Better evidence is needed to prove the identity between the action of glutamate and that of the natural excitatory transmitter. Some formidable technical problems are also likely to impede rapid progress in this direction. The reversal level of excitatory synaptic potentials is far removed from the resting potential, and therefore not easily attained with the small currents that can be carried by fine microelectrodes. Furthermore, many excitatory synapses may be situated remotely on the dendrites of pyramidal cells[42]; the corresponding synaptic events would give only small conductance changes and poorly defined reversal levels at the probable site of recording in the cell body. Finally, there are still no specific pharmacological antagonists of either excitation or of glutamate action.

Derivatives of Glutamate

L-Aspartic acid, the other dicarboxylic amino-acid found in the brain, has a strong excitatory action, comparable with that of L-glutamate[12,43]. But the longer-chain compounds, amino-pimelic and amino-adipic acids, are quite ineffective. The excitatory action depends rather critically on the presence of one amino and two acid groups: thus α-oxoglutaric acid (Fig. 2*C*), glutamine (Fig. 2*B*) and acetyl-aspartic acid are also practically ineffective; and the α-decarboxylation products of glutamate or aspartate (γ-aminobutyric acid or β-alanine) are powerful inhibitors of neuronal discharge discussed later. But a carboxyl group can be substituted with a sulphonic group; the resulting compounds are even more potent excitants than glutamate[12,43].

γ-Aminobutyric Acid and Inhibition

In contrast to glutamate, GABA was identified as an important brain constituent only relatively recently[44,45], probably because it is not found in any significant amount in other tissues, and its presence was therefore unexpected. Its functional role as a possible inhibitory transmitter became apparent when Elliott and his collaborators[46,47] identified GABA as the active agent in brain extracts which had a unique inhibitory action on crayfish stretch-receptors[48,49].

The powerful inhibitory effect of GABA on crustacean stretch-receptors and muscle was later shown to be indistinguishable from synaptic inhibition[50,51]. With the further demonstration that GABA is selectively released by stimulating inhibitory nerve fibres[52], it became probable that GABA is an inhibitory transmitter in crustaceans.

Hayashi[9] first noted that GABA and some other omega monocarboxylic amino-acids could inhibit mammalian cortical neurones. A depressant action was also observed by Purpura *et al.*[53] and Curtis and his collaborators[43,54], but neither group believed that GABA could be responsible

for the natural inhibition of central neurones. But further tests on the cerebral and cerebellar cortex[12] revealed such a powerful inhibitory effect (Fig. 5*A*) that GABA could not be ignored as a possible inhibitory transmitter. Later, intracellular recording and tests of membrane resistance[55,56] demonstrated a remarkable similarity between the effects produced by synaptic inhibition and by GABA. In both cases, there was a hyperpolarization—with a similar reversal level—and a great decrease in membrane resistance, chiefly attributable to an increase in Cl^- permeability (Fig. 6*A* and *B*)[38]. Comparable observations on neurones in Deiters's nucleus make it probable that GABA is the inhibitory transmitter released in the medulla by the endings of the cerebellar Purkinje cells[57].

Derivatives of GABA

Other short-chain omega-amino-acids and some related compounds such as guanidine derivatives are also potent inhibitors of central neurones (Fig. 5*B* and *D*)[9,12,43]. Physiologically, the most significant is glycine, which is probably an important inhibitory transmitter in the spinal cord[58]: many spinal neurones are more strongly inhibited by glycine than by GABA; and, like the best-known variety of spinal inhibition, the action of glycine is blocked by strychnine[59]. Glycine may be an inhibitory transmitter also in some parts of the brain stem[60,61]. But it is unlikely to have an important inhibitory function in the cerebral[62] or cerebellar[63] cortex, where it has only a very weak action (Figs. 5*C* and 6*C*).

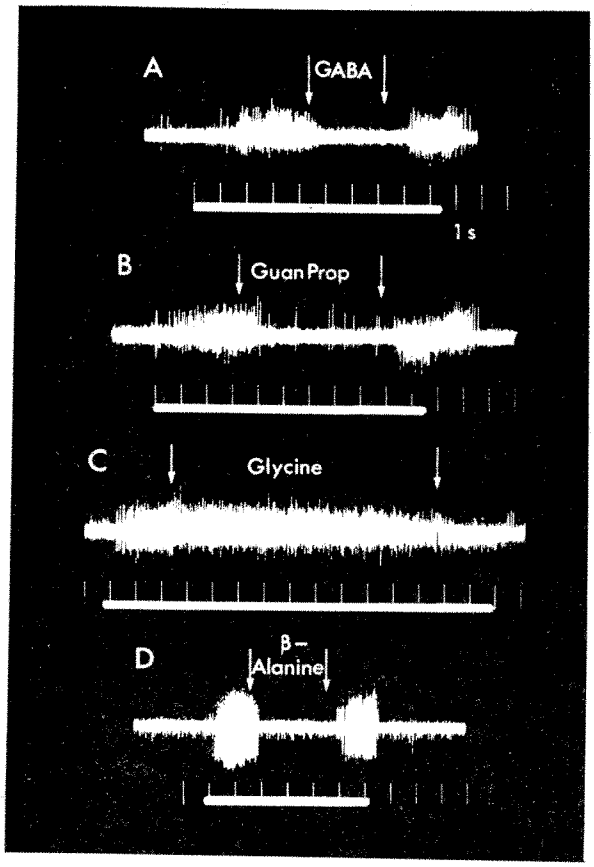

Fig. 5. Inhibitory action of GABA and some related amino-acids on cortical cells. In each case, neuronal discharge was initiated by release of glutamate (white line). (*A*) GABA (20 nA); (*B*) guanidino-propionic acid (20 nA); (*C*) glycine (100 nA), all tested on same group of cells; (*D*) effect of β-alanine (20 nA) in another experiment.

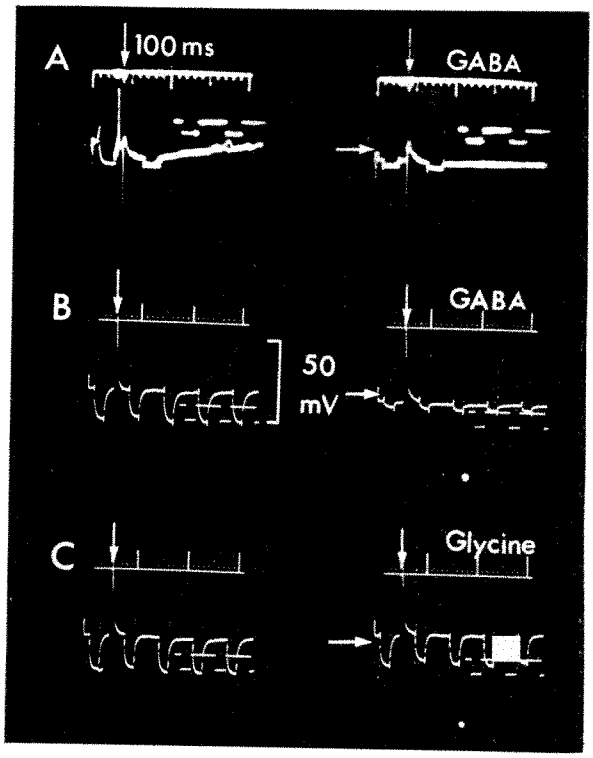

Fig. 6. Intracellular recording from cortical neurones showing inhibitory synaptic potentials (IPSPs) elicited by surface stimuli (at vertical arrows). Control traces are on the left. (*A*) IPSP shown after shock artefact as a downward (negative) deflexion, associated with a marked decrease in membrane resistance (note smaller voltage pulse developed by constant current pulses; the latter are monitored on another trace); when GABA was applied (140 nA), membrane potential became more negative (trace moved down) and resting resistance fell. (*B*) and (*C*) Traces obtained from another neurone: five resistance-testing pulses are visible in each. Note much smaller IPSP. GABA (28 nA) had a correspondingly smaller hyperpolarizing effect, but the membrane resistance was again much reduced. In contrast, a larger dose of glycine (56 nA) produced only a small change in resistance and some depolarization. Horizontal arrows indicate initial level of resting potential.

Metabolism and Localization in Brain

GABA is widely distributed in the brain[25,44,45]. Its production from glutamic acid (Fig. 1) is mediated by a highly specific enzyme, glutamic decarboxylase (GAD), which requires pyridoxal phosphate as coenzyme, and is inhibited by semicarbazide and hydroxylamine[64]. Other properties of this enzyme have been studied extensively[65]. A feature of some interest is that GAD is inhibited by Cl^-, so that an increase in the content of Cl^- in inhibitory cells, resulting from intense activity, could reduce substantially the rate of production of GABA[66]. GAD and GABA have an approximately similar distribution in the central nervous tissue[67,68]. The enzyme is not found in peripheral nerves or spinal roots and its concentration is greatest in areas of the brain stem that are exceptionally rich in GABA (such as the substantia nigra).

GABA-amino-transferase (GABA-T) is another relevant enzyme. By reversible transamination with α-oxoglutarate, it converts GABA to succinic semialdehyde, which, in the presence of an appropriate dehydrogenase[69], is oxidized to succinic acid (Fig. 1). Because succinic acid is a component of the tricarboxylic acid cycle, GABA is conveniently removed by this route. GABA-T is also present in the brain[70] but its distribution differs somewhat from that of GABA[67,71]. It seems that the content of GABA in a given region is determined by local GAD rather than GABA-T activity[67]. In the cerebellum and the hippo-

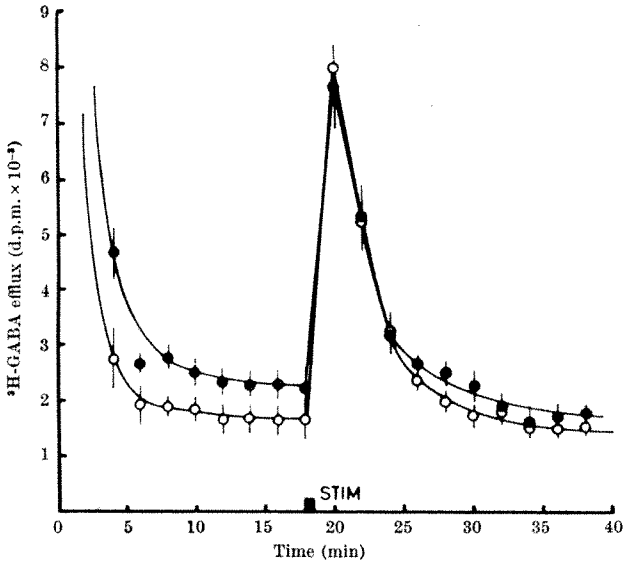

Fig. 7. Release of (^{3}H)-GABA from rat cortical slices by electrical stimulation (20 mA, 5 ms pulses at 100 Hz, for 30 s). ●—●, Normal; ○—○, Ca^{2+}-free. Mean values from seven experiments, with standard errors. (From Srinivasan *et al.*[84])

campus, the known situation of inhibitory neurones agrees with the distribution of GABA and the relevant enzymes[72,73].

GABA is too powerful an inhibitor to be freely distributed in the extracellular space of the brain. But GABA injected inside neurones does not alter their excitability[55]. GABA could therefore be stored inside cells. In fact, most of the GABA in the brain is probably actively kept in an intracellular compartment. Fluid left in contact with the surface of the brain contains at most only traces of GABA[40,74]. Slices of cerebral cortex absorb GABA, even against a very high concentration gradient[6,75]. This active process requires the expenditure of energy, and is therefore blocked by metabolic inhibitors.

Glutamate is apparently contained in more than one "pool" in the brain. One of these pools is in equilibrium with cerebral GABA but not glutamine; it is labelled very effectively through systemic glucose[30,31,39]. A second, smaller, pool seems to be accessible to systemic acetate, through which one obtains a high degree of labelling of glutamine but relatively little of GABA[27]; labelled glutamate injected directly into the brain[76] or systemically[77] also gives a high yield of labelled glutamine, probably by entering the same pool. These two pools may include, on the one hand, inhibitory nerve terminals which release or take up GABA and, on the other, excitatory terminals which release or take up glutamate. In the first pool, glutamate and GABA rapidly reach equilibrium through GAD and GABA-T activities. In the second, any excess glutamate may readily be stored in the inactive form of glutamine through glutamine synthetase.

Mechanism of Action and Uptake

A large increase in permeability to Cl^- fully accounts for the inhibitory action of GABA, because the gradient of Cl^- across the membrane is close to that for electrochemical equilibrium when the cell is in its resting condition; inward (repolarizing) movements of Cl^- therefore act as a powerful brake against any depolarizing (exciting) tendencies.

The precise mechanism by which GABA facilitates movements of Cl^- is not known. By analogy with glutamate, GABA might combine with a membrane carrier for Cl^-, increasing its affinity for the anion, and therefore accelerating Cl^- fluxes across the membrane (Fig. 3). If the binding of GABA to the carrier is a function of the ambient concentration of Cl^-, the usual low internal content of Cl^- would promote a net uptake of GABA. There is no direct evidence for this scheme, but some support is given by the observation that cortical slices absorb much less GABA in the absence of Cl^- or other halide anions (personal communication from Z. Gottesfeld and K. A. C. Elliott).

Although the active uptake of GABA by brain slices has been studied for some years, the precise localization of the absorbed GABA has been demonstrated only recently. According to Neal and Iversen[78], like endogenous GABA, nearly half of the labelled GABA taken up by cortical slices is found in nerve endings, which also contain most of the GAD activity in the tissue. These results thus confirm the presence of both GABA[32,34,39,79] and GAD activity[36,79,80] in cerebral nerve endings. Presumably at least part of the GABA absorbed by the slices is taken up directly by nerve endings, for even isolated nerve-ending particles can bind and take up external GABA[81,82]. In any case, when extracts of cortical nerve endings are tested directly on cortical cells[32], endings can be shown to contain enough GABA for a significant inhibitory action.

Release of GABA during Inhibition

If GABA is indeed an inhibitory transmitter, one should be able to demonstrate its release from inhibitory nerve endings, although only very small amounts are likely to escape from the tissue, even during the strongest inhibition, until a means is found of preventing the rapid uptake of extracellular GABA.

Some release of GABA from brain tissue has been demonstrated in experiments on brain slices, on isolated nerve endings or on the brain *in situ*. For example, if brain slices are incubated in a medium containing radioactive GABA, the subsequent efflux of labelled GABA into non-radioactive medium is very much accelerated by stimulating the slices electrically or with 40 mM K^+ [83,84]. Stimulating in a similar way a suspension of nerve endings—isolated by the technique of Gray and Whittaker[33]—causes a markedly greater proportional loss of GABA than of other amino-acids (except glutamate and aspartate)[41]. Jasper and his collaborators[40,74] have shown that appreciable amounts of GABA can sometimes be collected from the surface of the cortex; this efflux apparently depends on the functional state of the animal, being relatively large during sleep and practically undetectable after arousal. A more direct correlation with inhibitory function is evident when the efflux of cortical GABA is specifically accelerated by the activation of known inhibitory pathways; for example by stimulating the cortical surface, the thalamus[85], the caudate nucleus or the pyramids (personal communication from H. Jasper and I. Koyama).

Finally, Obata and Takeda[86] have shown that cerebellar stimulation increases the leakage of GABA into the fourth ventricle. This is particularly significant because the cerebellar cortex has a solely inhibitory action on nuclei adjacent to the ventricle[87]. Both in cerebellar and cerebral experiments, the yields of GABA are substantially greater when animals are pre-treated with inhibitors of GABA-transaminase.

In crustaceans the inhibitory action of GABA is blocked very effectively, and specifically, by the convulsant agent

picrotoxin[47,91,92]. Unfortunately, such a clear antagonism of GABA has not so far been observed regularly in the vertebrates, with picrotoxin or any other compound. As already mentioned, the inhibitory action of glycine is prevented by strychnine; but strychnine has little effect on inhibition by GABA[59,93,94]. Picrotoxin may antagonize the action of GABA on certain neurones in the brain stem and spinal cord[93,95], but really convincing antagonism has not yet been demonstrated in the cerebral or cerebellar cortex. Curtis *et al.*[96] have stated that the alkaloid bicuculline blocks selectively the inhibitory action of GABA in the brain and spinal cord, and that this drug should be useful for detecting GABA-mediated inhibition. But repeated tests by prolonged direct applications on cerebral cortical neurones have failed to confirm these observations[97]: it seems unlikely that bicuculline can be of great value as a specific antagonist of GABA.

In summary, there is now much evidence to suggest that the most important functions of L-glutamate and GABA are to act respectively as excitatory and inhibitory neurotransmitters. That the glutamate-GABA metabolic pathway (Fig. 1) can use up a substantial fraction of the total oxygen consumed by the brain[88] may be an indication not of its importance for general metabolism, but rather of the large amount of energy needed to maintain an adequate supply of these essential transmitters. Thus although cerebral glutamate first became well known because of its effects on the oxygen consumption and the sodium and potassium contents of the brain, these are probably secondary manifestations of transmitter functions. Of course, glutamate is also involved in the synthesis and breakdown of cerebral proteins[29,89]. But even these slower processes may be considered aspects of neurotransmission, for they probably determine the long-term synaptic facilitations or inactivations required for learning and memory.

Experiments involving rifampicin show that 5S RNA is generated from a transcription unit carrying between thirteen and thirty times the amount of genetic information necessary for the production of one molecule.

ACCUMULATION of higher molecular weight precursors of mature 16S and 23S ribosomal RNA (m16 and m23) has been demonstrated in bacterial cultures in which the maturation of these precursors is prevented by inhibition of protein synthesis[1]. More recently, polyacrylamide gel electrophoretic techniques have facilitated the demonstration of the transient existence of such macromolecular precursors (termed p16 and p23) in normally growing cultures of *Bacillus subtilis*[2] and *Escherichia coli*[3,4]. Woese and his collaborators[5,6] have shown that, in *B. subtilis*, the other two "stable" RNA species, 5S ribosomal RNA and 4S (transfer) RNA, are also secondarily derived from substantially larger macromolecules. In the case of *E. coli* 5S RNA, however, results from this laboratory[4] and a recent report by Adesnik and Levinthal[3] are in contradiction. The kinetic experiments of Pace *et al.*[4] suggest that *E. coli* 5S RNA is the product of post-transcriptional modification, while those of Adesnik and Levinthal indicate that it is not. We describe here an alternative approach to this problem using the antibiotic rifampicin, which inhibits the initiation of transcription by *E. coli* RNA polymerase, but allows completion of transcriptional events already initiated[7,8].

This approach is perhaps best understood in terms of two possible models for the molecular origin of 5S RNA (Fig. 1). Here we define a "transcriptional unit" as a segment of DNA bounded by (and including) a single transcription initiation site and a single transcription termination site, which is transcribed without interruption by any RNA polymerase molecule which effectively begins RNA synthesis at the initiation site. A transcriptional unit may comprise one or many genes. (If an operator region is included, then the transcriptional unit is properly called an "operon".) In model A (Fig. 1), 5S RNA is the product of a small transcriptional unit (5S DNA) which carries little or no additional genetic information. In model B, 5S DNA is included within, and near the termination site of, a considerably larger transcriptional unit. The primary transcription product of this unit is a large RNA molecule which is secondarily cleaved into 5S RNA and one or more other RNA species ("X-RNA"). It should be noted, however, that such cleavage might occur before transcription of the 5S DNA segment is completed. If new initiations are prevented by the addition of rifampicin, and isotopic label is added immediately, incubation being continued until all RNA synthesis has stopped, the amount of label incorporated into 5S RNA will depend on the size of the transcriptional unit from which it is derived or, more precisely, on the number of molecules of RNA polymerase bound to that transcriptional unit at the time of antibiotic addition. There are indications that the 5S DNA segment can probably accommodate no more than two simultaneously transcribing RNA polymerase molecules[9], and in our conditions (0·55 generations/h) it presumably carries only one such molecule at any instant. This single polymerase molecule will, on average, have traversed about one half (fifty-five nucleotide pairs) of the 5S DNA segment. Thus, if rifampicin and then label are added, this polymerase will incorporate approximately fifty-five nucleotides from the labelled pool into 5S RNA (see Fig. 3 for experimental details). Let this amount of label correspond to one half "unit" of radioactivity, where one unit is that amount of radioactivity expected in one fully labelled 5S RNA molecule.

If model A is correct, only this one half unit of radioactivity incorporated by the single polymerase bound to 5S DNA will be found in 5S RNA, because no further transcription of 5S DNA can be initiated in the presence of rifampicin. With model B, however, each of the n polymerase molecules bound to X-DNA at the time of

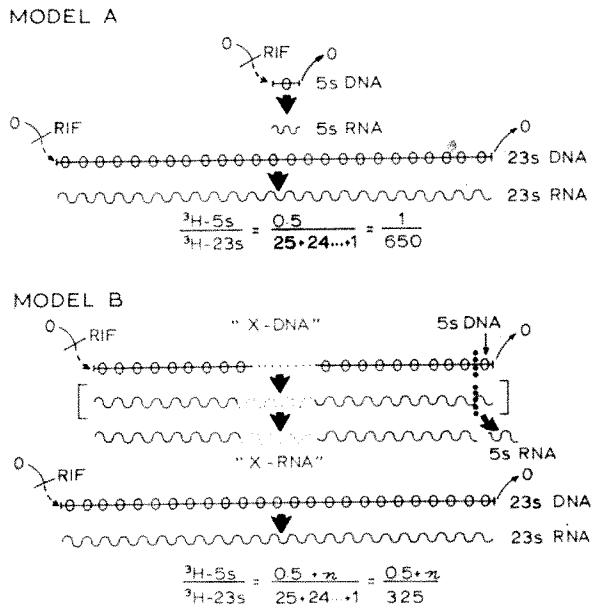

Fig. 1. Two models for the transcriptional unit containing 5S RNA. In model A, 5S RNA is the product of a small gene carrying no additional information. On average, one RNA polymerase molecule (oval) is bound to this gene at any given time, while 25 polymerase molecules are bound to the 23S transcriptional unit. In model B, 5S RNA is near the termination site of a larger transcriptional unit. Transcription is begun only at the initiation site of this DNA unit, producing a large RNA species which is cleaved to "X-RNA" and 5S RNA, possibly even before transcription termination and its release from the DNA. The expected ratios of labelled 5S RNA to labelled 23S RNA synthesized after inhibition of transcription initiation by rifampicin (RIF) are shown for both models. (See text for further explanation.)

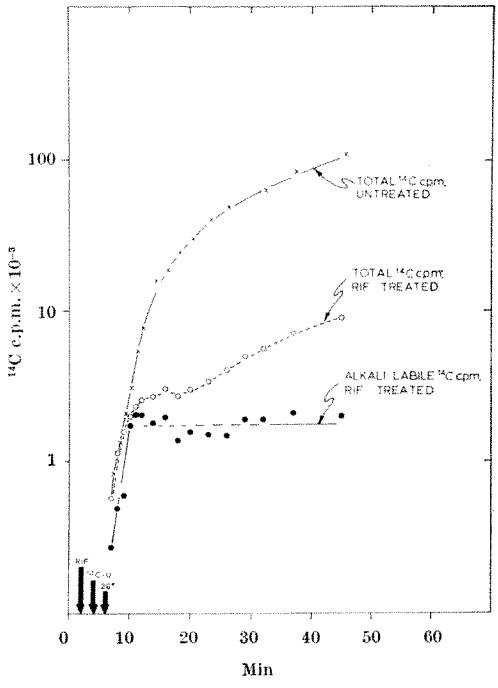

Fig. 2. Incorporation of ^{14}C-uracil into total TCA precipitable and alkali-labile TCA precipitable material. A culture of AB 257 at 26° C in methionine supplemented minimal medium[10] containing 20 μg/ml. uracil was chilled to 0° C and divided into two 20 ml. subcultures at zero min. After two min, rifampicin (Pittman-Moore lot D-1238) was added to one culture to a concentration of 300 μg/ml. and an equivalent volume of acetone (in which stock solutions of rifampicin were made) to the control culture. ^{14}C-Uracil (50 μCi, International Chemical and Nuclear Corp.) was added to each culture at 4 min and at 6 min; the cultures were rapidly warmed to 26° C. Samples (0·5 ml.) were taken during shaking at 26° C and either (*a*) directly precipitated with cold 5 per cent trichloroacetic acid (TCA) and collected on glass fibre filters for the determination of total number of c.p.m. incorporated, or (*b*) mixed with an equal volume of 0·5 M NaOH and incubated at 37° C for 24 h before neutralization and TCA precipitation as above. The lower curve was obtained by subtracting alkali-stable from total TCA precipitable counts.

antibiotic addition will transcribe the 5S DNA segment, producing n additional units of radioactivity in 5S RNA, and if polymerase molecules are distributed evenly across X-DNA and 5S DNA, as expected with only one initiation site, then n equals the ratio of the lengths of X-DNA to that of 5S DNA.

Although the absolute amount of 5S RNA labelled after rifampicin addition could be calculated if the specific activities of this species and of the precursor pool were known, it is simpler and perhaps more precise to consider the ratio of label incorporated into 5S RNA to label incorporated into a second, preferably larger, species of RNA. The second species we have chosen is 23S RNA, which, although not a primary transcription product, is of nearly the same size as the macromolecular precursor(s) from which it is derived[3,4] and which may be the "X-RNA" postulated in model B.

Because 23S RNA is approximately twenty-five times larger than 5S RNA and is normally produced in the same molar quantities in the cell, we expect twenty-five molecules of RNA polymerase to be transcribing 23S DNA at the time of antibiotic addition. This will result in the incorporation of $25+24+23+\ \ldots\ .+1=325$ "units" of label (as defined above) into 23S RNA. For model A, therefore, the ratio of label incorporated into 5S RNA to label incorporated into 23S RNA after rifampicin addition will be 1 : 650, and for model B will be $(n+0{\cdot}5) : 325$. The ratio of labelled 5S to labelled 23S RNA found in steady state or long pulse labelled RNA preparations is 1 : 25. Thus if model A is correct, one would expect a drastic reduction in this ratio in antibiotic treated cultures with essentially no incorporation of label into 5S RNA. In model B, however, the ratio depends on n, and can even exceed the steady state ratio if n is greater than 13. These predictions depend qualitatively neither on the exact spacing of polymerase molecules nor on gene dosage. That is, with model A, 5S : 23S ratios will always be considerably reduced by rifampicin treatment, and with model B they will be increased if n is sufficiently large.

Shut-off of Initiation by Rifampicin

It is first necessary to show that rifampicin, at an appropriate concentration, inhibits initiation of transcription in *E. coli in vivo*, as it is known to do *in vitro*. The strain chosen was AB 257 (*HfrC*, *metB*$^-$, *rel*$^-$), a K12 strain derived from 58–161, and similar if not identical to the strain EA2 used by Adesnik and Levinthal[3].

The kinetics of incorporation of ^{14}C-uracil into acid insoluble material after addition of rifampicin were determined in an experiment illustrated in Fig. 2. Several conclusions can be drawn from this figure: (*a*) rifampicin inhibits ^{14}C-uracil incorporation only after a lag of several minutes, as expected from the *in vitro* demonstration that chain elongation is not affected by this drug, (*b*) the incorporation of ^{14}C-uracil into TCA precipitable material is not completely inhibited by 300 μg/ml. rifampicin, but (*c*) this residual incorporation does not reflect RNA synthesis, for the labelled material is not rendered TCA soluble by alkaline hydrolysis. The lower curve in Fig. 2 represents the difference between alkali stable and total TCA precipitable counts incorporated by the rifampicin treated culture, and indicates that RNA synthesis is completely inhibited. Similar results were obtained using ^{3}H-uridine in place of ^{14}C-uracil.

Residual 23S and 5S RNA Synthesis

The relative accumulation of 5S and 23S RNA during transcription in the presence of rifampicin was determined in the following manner. A culture was prelabelled with ^{32}P-orthophosphate, chased by further growth in non-radioactive medium, chilled to 0° C and divided into two subcultures. Rifampicin was added to one culture, and then ^{3}H-uridine was added to both cultures, which were maintained at 0° C throughout this period to minimize RNA chain elongation during equilibration with the antibiotic and the isotopic label[11]. Incorporation of ^{3}H-uridine into RNA begins immediately on warming to 26° C (see Fig. 2) and incubation was continued at 26° C for 14 min, that is, for some 10 min after residual incorporation of radioactivity into RNA ceases. RNA was purified from both cultures by phenol extraction and individual RNA species were resolved by polyacrylamide gel electrophoresis. The resulting gel profiles are illustrated in Fig. 3, in which the radioactivity in each gel slice is plotted as a percentage of the total radioactivity retained in the gel. It is immediately apparent that the relative amount of label (^{3}H) in 5S RNA, as well as the ratio of labelled 5S RNA to 23S RNA, is greater after rifampicin treatment than with either the chased ^{32}P-prelabel or the 14 min continuous ^{3}H-uridine labelling in the control culture. This eliminates model A of Fig. 1, where ^{3}H radioactivity in 5S RNA should be considerably reduced by antibiotic treatment.

The percentages of total radioactive label in 23S RNA and 5S RNA for both experimental and control cultures are shown in Table 1. (Correction has been made for the loss of that material from 2·8 per cent gels which is retained on 8 per cent gels.) These results are consistent with model B, where the gene for 5S RNA is transcribed as part of a larger unit, and preceded in that unit by a segment of DNA of considerably greater size.

5S RNA is not Synthesized Preferentially

This conclusion rests, of course, on the assumption that the initiation of the synthesis of both RNA species is equally sensitive to rifampicin inhibition, and that 5S

RNA does not continue to accumulate during the labelling period. This assumption is verified by the experiment illustrated in Fig. 4. A culture was chilled and treated with rifampicin as described for the previous experiment, and then divided into subcultures to which 1 mCi of ^{3}H-uridine was added at various times after initiating transcription by warming to 26° C. The absolute amounts of both labelled 23S and labelled 5S RNA decreased very rapidly after the culture was warmed. It is clear that essentially no RNA of either type is synthesized in the period between 11 and 24 min after warming, and that if preferential residual synthesis of 5S RNA occurs, it is not sufficient to account for the increase in 5S : 23S ratios shown in Table 1.

Implications

The data presented can be interpreted in two ways, both of which require that 5S DNA be part of a larger tran-

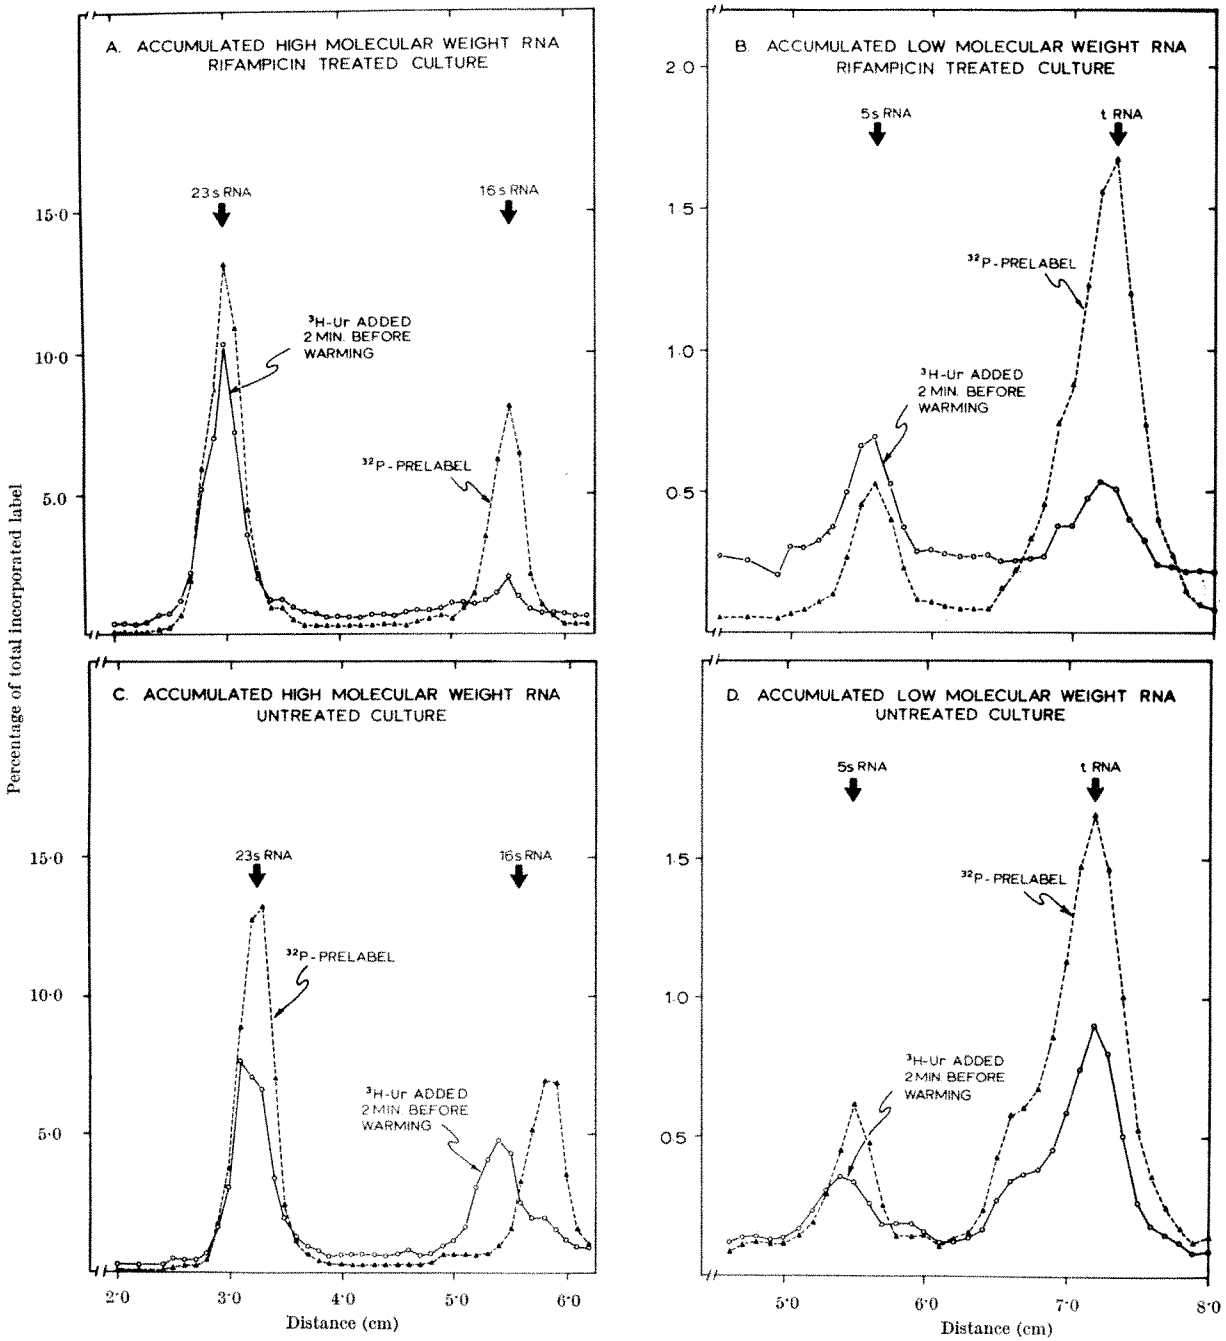

Fig. 3. Residual 23S and 5S RNA synthesis after rifampicin addition. A culture of AB 257 growing at 26° C in methionine supplemented minimal medium containing 0·025 mCi/ml. ^{32}P-orthophosphate (International Chemical and Nuclear Corp.) was washed and resuspended in non-radioactive medium containing 20 μg/ml. uridine. After a 30 min "chase" of the ^{32}P-prelabel the culture was chilled to 0° C and divided into two 4 ml. subcultures. 2 min after chilling, rifampicin was added to one subculture to a final concentration of 300 μg/ml., and an equivalent volume of acetone was added to the control subculture. 4 min after chilling, 1 mCi of ^{3}H-uridine (Schwarz Bioresearch, Inc.) was added to the rifampicin containing subculture, and 0·05 mCi of ^{3}H-uridine was added to the control. At 6 min, both cultures were rapidly warmed to 26° C and shaken vigorously at 26° C for 14 min. Both cultures were then rapidly chilled to 0° C in the presences of 10^{-3} M KCN, washed once in cold 10^{-3} M Tris (*p*H 7·4) and 10^{-3} M $MgCl_2$, and quickly frozen. RNA was purified by phenol extraction and resolved on 2·8 per cent and 8·0 per cent polyacrylamide gels as described previously[4,12]. (Note that during the relatively short, unchased pulse with ^{3}H-uridine, most of the labelled 16S RNA remains in precursor form in the control culture.)

scriptional unit. The first is that 5S RNA is generated from a transcriptional unit carrying considerably more genetic information than is necessary to specify 5S RNA alone and that the 5S DNA region is at some distance from the transcription initiation site of this unit. This does not necessarily imply that a large RNA molecule corresponding to the entire transcriptional unit exists independently in the cell for any appreciable length of time; indeed, 5S RNA could be cleaved from the remainder of this macromolecule ("X-RNA") before transcription of the 5S DNA segment is even completed. Data of the type presented in Fig. 3 and Table 1 make it possible to determine n, the ratio of the length of the postulated DNA segment preceding 5S DNA in the transcriptional unit to the length of 5S DNA. From Table 1, this value would appear to be about thirty. The high backgrounds of label observed across our 8·0 per cent gels, however, make precise measurement of the amount of 5S RNA difficult, and in two other experiments similar to that illustrated in Fig. 3, n is approximately twenty. In no case, however, is the ratio of labelled 5S RNA to labelled 23S RNA in rifampicin treated cultures as low as that observed in steady state conditions. According to this interpretation, 5S DNA is preceded by a segment of DNA at least thirteen times, and possibly thirty times, its own length in the transcriptional unit of which it is part. The other RNA product(s) of this unit cannot be identified by this approach.

The alternative interpretation of our results is that 5S RNA is derived from a transcriptional unit consisting of fifteen to twenty repeating genes for 5S RNA, there being only one such transcriptional unit per genome. Cleavage into individual 5S RNA molecules could occur either during or immediately after completion of transcription of this large unit.

This approach using rifampicin provides a method for measuring the size of transcriptional units in a manner complementary to the approach using actinomycin D developed by Bleyman *et al.*[6]. We are currently using rifampicin to examine the relationship, if any, between the genes for 16S and 23S RNA. It is apparent in Fig. 3*A*, and has been found in other experiments, that the incorporation of label into 16S RNA is much more inhibited by rifampicin than is incorporation of label into 23S RNA, but the high background radioactivity observed across these gels does not yet permit precise measurement. Further, it is possible to determine the size of the transcriptional units from which the transfer RNA species are derived. If each tRNA gene were itself a single transcriptional unit, then more label than expected is incorporated into tRNA after antibiotic treatment (Fig. 3*B*).

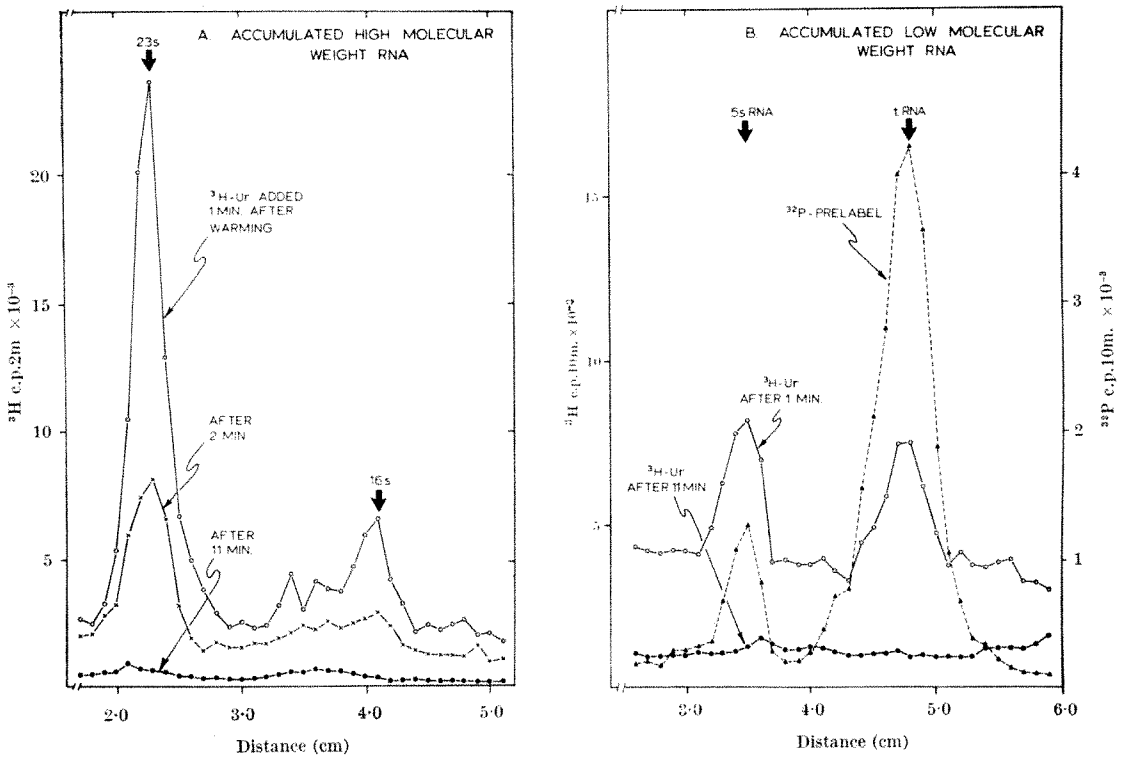

Fig. 4. RNA synthesized at various times after addition of rifampicin. A culture of AB 257 (at 26° C) was prelabelled with ^{32}P-orthophosphate, chased, and chilled as described for Fig. 3. 2 min after chilling, rifampicin was added to a final concentration of 200 μg/ml. and the culture was divided into eight subcultures. At 6 min, the subcultures were warmed to 26° C and vigorous shaking was begun. 1 mCi of ^{3}H-uridine was added to each subculture at times before and after warming. 24 min after warming, RNA was extracted from all cultures and fractionated on 2·8 per cent and 8·0 per cent gels. *A*, Representative 2·8 per cent gel profiles for RNA extracted from subcultures to which ^{3}H uridine was added at 1, 2 and 11 min after warming. *B*, Representative 8·0 gel profiles for RNA from subcultures labelled at 1 and 11 min. The profile of ^{32}P-prelabelled material is shown to indicate the positions of 4S and 5S RNA within the gels.

Table 1. RELATIVE ACCUMULATION OF 5S AND 23S RNA IN RIFAMPICIN TREATED AND CONTROL CULTURES

	^{3}H-labelled RNA (percentage of total)			^{32}P-prelabelled RNA (percentage of total)		
	5S	23S	5S/23S	5S	23S	5S/23S
Rifampicin-treated	2·27	22·4	0·101	1·52	37·8	0·040
Control culture	0·99	22·1	0·045	1·71	38·0	0·045

Fractions of total ^{32}P and ^{3}H radioactivity in the 5S and 23S RNA regions of the gel profiles (Fig. 3) were aggregated. In the case of ^{3}H radioactivity, a background, corresponding to radioactivity in gel slices adjacent to the 5S or 23S region was subtracted from each of the summed points.

We thank Professors C. R. Woese and Howard V. Rickenberg for their suggestions and encouragement. W. F. D. is a postdoctoral fellow of the US National

Cancer Institute. This work was supported by a US National Institutes of Health grant to N. R. P.

Applications of hormones to fully expanded leaves of dwarf bean stimulate the activity of carboxydismutase. The increase in enzyme activity is not paralleled by synthesis of plastid ribosomal RNA nor is there a demonstrable enhancement of synthesis of fraction I protein. These results are interesting in relation to the activities of other photosynthetic enzymes.

We have reported[1,2] immediate increases in photosynthetic rates of maize, bean and clover leaves of dwarf mutants after applications of gibberellin A_3 (GA_3) and kinetin. Moreover, the increases in light-saturated photosynthesis, measured by infrared gas analysis or $^{14}CO_2$ methods, were closely paralleled by enhanced specific activity of the photosynthetic enzymes ribulose-1,5-diphosphate carboxylase (RuDPC) and phosphoenolpyruvate carboxylase in clover and maize, respectively. Feierabend[3] has reported stimulated rates of synthesis of photosynthetic enzymes after application of kinetin during the greening of etiolated leaves exposed to light. The question thus arises as to whether hormones affect the synthesis or activity of photosynthetic enzymes.

The bulk of fraction 1 protein synthesis and RuDPC synthesis occurs during the expansion phase of the leaf and thereafter only a low turnover can be detected[4]. Moreover, synthesis of plastid ribosomal RNA soon declines after the early stages of leaf development, although synthesis of cytoplasmic RNA continues[5]. We therefore decided to carry out parallel investigations of plastid rRNA synthesis, fraction I protein synthesis and RuDPC activity with leaves of varying age, with effects of GA_3 and kinetin superimposed on this study.

The simultaneous study of plastid and cytoplasmic rRNA in the same extract is made possible by the high resolution obtained with the polyacrylamide gel technique of Loening[6]. Incorporation of the precursors ^{3}H-cytidine and $H_3{}^{32}PO_4$ was achieved by feeding through either the excised stems of seedlings or the cut petioles of leaves, for periods of 4–6 h. Immersed portions of plant material were discarded in order to minimize effects of bacterial contamination. Total nucleic acid was extracted using the phenol method[7] and fractionated on 2·4 per cent acrylamide gels at 5 mA/tube for 2–3 h in Tris-acetate buffer, *p*H 7·2. The gels were scanned at 265 nm and frozen and sliced into 1 mm sections which were hydrolysed with 1 ml. of 10 per cent piperidine at 80° C. Radioactivity of the gel sections was determined by liquid scintillation counting in toluene/'Triton X-100' (2/1 v/v) containing 0·27 per cent PPO.

The separations of the RNA components from leaves at three stages of development are shown in Fig. 1. In the very young leaves there was marked incorporation of precursors into both Pr-RNA and cytoplasmic rRNA; at this early stage the amount of plastid rRNA was small

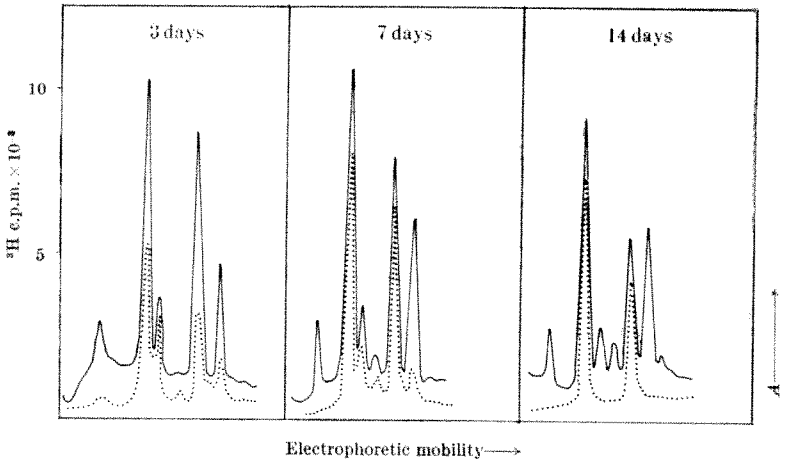

Fig. 1. Gel fractionation of nucleic acid prepared from leaves of *Phaseolus* at three stages of development. Electrophoresis was carried out for 2·5–3 h in Tris-acetate buffer, *p*H 7·2. ———, Absorbance; · · · · , ^{3}H-cytidine incorporated.

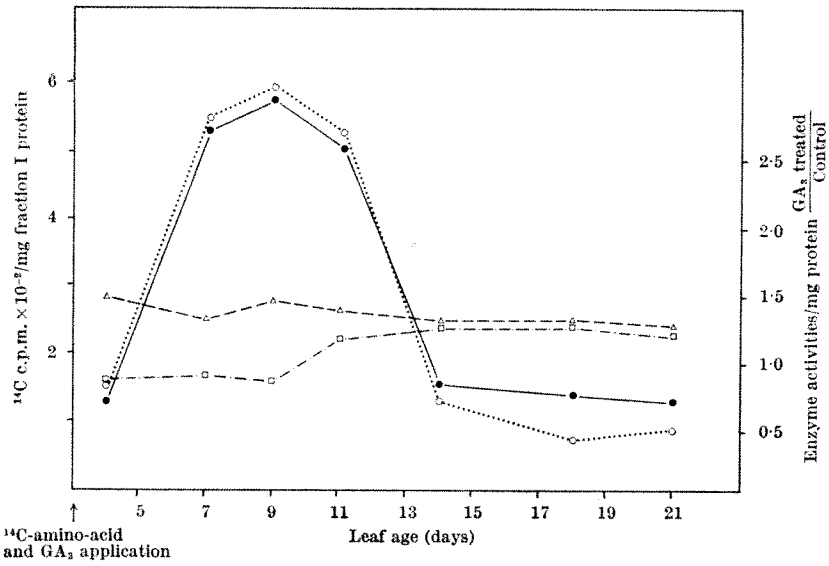

Fig. 2. Effects of GA_3 on incorporation of ^{14}C-amino-acid into fraction I protein (●—●), and activities of RuDP carboxylase (□ — · —□) and fructose-1,6-diphosphatase (FDP) (△ - - - △) in *Phaseolus vulgaris*. ○ - - - ○, Control.

in relation to the cytoplasmic fraction. The ratios of radioactivity incorporated and of plastid rRNA to cytoplasmic RNA content for the different stage of growth are given in Table 2. The plastid rRNA content was greatly increased in the 7–8 day old leaves relative to the cytoplasmic RNA component, but the absolute rate of incorporation of precursors into the plastid rRNA fraction was significantly lower at this stage. Both precursors gave identical results in these experiments and the data clearly indicate that the plastid rRNA is synthesized at early stages of leaf development, demonstrable with these labelled precursors. When 14 day old leaves were exposed to either ^{32}P or labelled base, however, there was no detectable incorporation into plastid rRNA, whereas massive amounts of label were located in the cytoplasmic rRNA fractions. This suggested that there is very little or no synthesis of plastid rRNA in fully expanded leaves of *Phaseolus*. Nevertheless, it was possible that failure to demonstrate incorporation of these precursors into plastid rRNA in expanded leaves could be due either to cytoplasmic dilution or to a change in the permeability characteristics of the chloroplast membrane, resulting in failure of the precursors to reach the site of synthesis. Consequently, both young and mature leaves were exposed to $^{14}CO_2$ and the labelling pattern of the ribosomal RNA bands examined. A marked incorporation into plastid rRNA was obtained with young developing leaves, but the label in this rRNA was negligible with expanded leaves, cytoplasmic rRNA being labelled at both stages of leaf growth. We conclude, therefore, that the bulk of plastid rRNA is synthesized in bean chiefly during the early development of the leaf. This is supported by observation on radish leaves and agrees with recent findings[4,5]. No significant effects of either GA_3 or kinetin on the specific radioactivity of the plastid rRNA components could be detected at any growth stage examined (Table 1). RuDPC activity, however, was enhanced by the addition of both GA_3 and kinetin to fully expanded 20 day old leaves, which therefore suggests that the mechanism of enzyme stimulation by the application of hormones does not act through the synthesis of plastid rRNA and presumably does not involve *de novo* plastid protein synthesis (unless it is occurring on existing ribosomes).

Table 1. EFFECTS OF HORMONE APPLICATIONS ON PHOTOSYNTHETIC ACTIVITY AND *in vitro* PROTEIN SYNTHESIS IN FULLY EXPANDED LEAVES OF *Phaseolus vulgaris* L.

Treatment of leaves (p.p.m. hormone)	Leaf PR (c.p.m./ cm^2/min × 10^{-3})	RuDPC activity /mg fresh weight ×10^{-4}	RuDPC activity /mg protein ×10^{-6}	^{14}C-leucine incorporated /mg fresh weight	^{14}C-leucine incorporated /mg protein
Control	4·17	1·37	1·71	1,875	546

K (1)	5·13	1·60	2·13	1,810	458
BAD (30)	5·50	1·85	2·32	1,551	423

PR, photosynthetic rate.

This proposal was tested in experiments where incorporation of labelled amino-acids into fraction 1 protein was determined in the presence and absence of hormone supplements. In the initial investigation, cotyledonary leaves of bean were given a single treatment with a synthetic ^{14}C-amino-acid mixture (Amersham CFB-104) in a dose of $2{\cdot}2 \times 10^5$ c.p.m. 3 days after the appearance of leaves. The plants were maintained at 15° C in natural daylight with a 12 h photoperiod, one batch acting as unsupplemented controls and the other treated with a solution of 100 p.p.m. ($2{\cdot}9 \times 10^{-4}$ M) of GA_3. Matched pairs of treated and control plants were sampled at intervals for 18 days and extracted in Tris (0·04 M), *p*H 7·8, containing 0·01 M $MgCl_2$, 0·25 mM EDTA, and 4 mM GSH. After centrifugation of extracts at 20,000*g*, determinations of enzyme activities, soluble protein content (Lowry method) and radioactivity were made on the supernates. Samples of 100 μl. were subjected to electrophoresis on polyacrylamide gel slabs (6·5 per cent) in Tris-citrate buffer, *p*H 9·0, containing 5 mM GSH. The gels were run at 2° C in 0·05 M borate buffer, *p*H 9·0, for 3 h with a current of 15 mA per gel. A reference gel was stained with amido black and the corresponding fraction 1 zones were excised from the simultaneously run replicates. These gel sections were used (*a*) for determination of RuDPC activity, (*b*) for protein determination and (*c*) to estimate the amount of ^{14}C incorporated into fraction 1 protein from the precursor amino-acid supplied. Changes in the specific radioactivity of the fraction 1 protein for hormone treated and control plants are presented in Fig. 2. No significant effect of GA_3 on the specific radioactivity was observed during the first 10 days after treatment. Thereafter, GA_3 retarded the loss of radioactivity from the fraction 1 zone, which is consistent with the findings of Goldthwaite and Bogorad[8] who demonstrated that GA_3 retarded the loss of radioactivity from RuDPC in leaf disks of *Rumex crispus*. But this is not applicable to the young leaf, and it is notable that the short time courses for stimulatory effects of both GA_3 and cytokinins, in intact leaves, are not consistent with the much longer periods required for the manifestation of effects attributable to retarded senescence. Moreover, the pattern of active protein synthesis observed parallels the pattern of synthesis of plastid rRNA obtained in the previous experiments. The effects of application of GA_3 on RuDPC and fructose-diphosphatase (FDP) activities are also shown in Fig. 1, the data being presented as ratios of control to treated values. As was expected from our previous studies on hormone concentration effects, addition of GA_3 to the very young leaves, where endogenous concentrations of hormone are presumably high, resulted in depressive effects of RuDPC activity per unit protein. After the tenth day after treatment, however, all assays revealed stimulations in the order of 20–30 per cent after application of GA_3. It is interesting that the activities of FDP (Fig. 1) and phosphoribulokinase (data not shown) per unit protein were higher in the GA_3 treatment at all growth stages.

A further experiment was conducted to determine

Table 2. EFFECTS OF GA_3 AND KINETIN ON INCORPORATION OF ^{3}H-CYTIDINE INTO PLASTID rRNA AT THREE STAGES OF LEAF DEVELOPMENT IN *Phaseolus*

Leaf age (days after appearance)	Plastid rRNA / Cytoplasmic rRNA	c.p.m. incorporated into plastid rRNA / c.p.m. incorporated into cytopl. rRNA

rates of synthesis of fraction 1 protein in leaves at four stages of development, coupled with effects of GA_3 and kinetin. The hormones were applied to attached leaves followed by labelled amino-acids. Leaf extracts, enzyme activities and fraction 1 protein separations were carried out as in the previous experiment. Table 2 shows that there was active synthesis in the young developing leaves, some 60–65 per cent of the labelled amino-acid in the leaf homogenate being located in fraction 1 protein. The rate of synthesis became progressively lower with increasing leaf age, some 9–10 per cent of label being located in the fraction 1 component in the 7–8 day old leaves, while only 2 per cent of incorporated label was found in protein of 12 day old leaves. The gibberellin treatment depressed the incorporation of amino-acid into fraction 1 protein in the young leaves, confirming our previous result, but had no significant effect in the later stages. A similar pattern was observed with the activity of RuDPC, which was depressed by GA_3 in the young leaves, but enhanced in the two later growth stages. The endogenous levels of free gibberellin in the leaves at the four stages studied are shown in Table 3. The specific radioactivity of the fraction 1 protein of leaves treated with kinetin was about 20 per cent higher than the control values in the phase of very active synthesis, but when the figures were corrected for differences of uptake of amino-acid into leaves, no significant difference between control and hormone treatment was evident. Although there was no effect of application of kinetin on RuDPC activity in the very young leaves, there was a marked stimulation in activity at the later stages, with no corresponding detectable increase in incorporation of labelled amino-acid into fraction 1 protein. In view of the very low incorporation of radioactivity in the 18 day old leaves, the experiment was repeated using 18 day old trifoliate leaves with a larger dose of amino-acid. Hormone treatments enhanced the activity of RuDP carboxylase but again no detectable increase in rate of fraction 1 protein synthesis was observed.

These results are somewhat difficult to interpret. On the one hand, applications of GA_3 and cytokinin to mature bean leaves result in significantly higher RuDPC activity within 24 h. In view of the well known effects of both hormones on the synthesis of proteins, it might have been expected that their effects on the level of RuDPC activity could be ascribed to stimulation of enzyme synthesis. There seems, however, to be little or no synthesis of plastid rRNA or of fraction 1 protein in leaves of bean once they have fully expanded. Thus it would seem that the stimulated activity of RuDPC after the application of the hormones can be ascribed to activation of the enzyme rather than to synthesis of new enzyme, although how such activation could occur remains obscure. Alternatively, it might be that the increase in RuDPC activity is due to its release from an inactive form as in the well known conversion of trypsinogen to trypsin.

It should, however, be pointed out that the measurements of incorporation of labelled precursors into plastid rRNA and fraction 1 protein can be obscured by pool dilution or permeability effects. It is also interesting that the observation of little or no synthesis of plastid rRNA in mature leaves does not preclude the possibility that there may be synthesis of plastid messenger or transfer RNA, for acrylamide gel fractionation of leaf RNA does not separate the plastid and cytoplasmic components of these species. Furthermore, it is clear from our other work that the fraction 1 protein, which contains the RuDPC activity and is separated as one major band by gel electrophoresis, has various other enzyme activities, for example, malate dehydrogenase and peroxidase, associated with it. It may well be that *de novo* synthesis of RuDPC in response to hormone treatments is so small in relation to the total amount of fraction 1 protein that further synthesis of the enzyme might not be detected. By the same token, however, by expressing the activities of RuDPC in terms of unit fraction 1 protein we may well be underestimating the extent of stimulation produced by the hormone applications. Finally, it is possible that the active form of RuDPC is synthesized in the cytoplasm or in a soluble plastid fraction and then becomes associated with fraction 1 protein of the plastid. The possibility of hormone stimulated enzyme synthesis in the cytoplasm is certainly not excluded by the available experimental data, and support for the contention of synthesis of a minor soluble component has been provided by Wildner and Criddle[9]. The observed increases in specific activities of fructose diphosphatase and phosphoribulokinase, which are not associated with fraction 1 protein in our experiments, make it necessary to defer conclusions on the implication of protein synthesis in the effect of GA_3 until labelling of RuDPC can be separated from that of the other components of fraction 1 protein.

Selective Synthesis of a Nuclear Acidic Protein in Liver Cells stimulated by Cortisol

by
KEITH R. SHELTON
VINCENT G. ALLFREY
The Rockefeller University, New York

Differential labelling experiments establish that synthesis of a non-histone protein of molecular weight 41,000 is specifically enhanced in response to the injection of cortisol into rats.

THIS report is concerned with the metabolism of a particular class of acidic proteins associated with DNA in the cell nucleus. It is now well established that chromosomal proteins influence the synthesis of RNA. Histones, for example, have been shown to inhibit DNA-directed RNA synthesis[1–5], although their uniformity in composition[6] and their regular distribution in diverse cell types suggest that they are unlikely to be primarily responsible for all the features of the control of transcription in the chromosomes of differentiated tissues. Instead, much of the specificity seems to reside in more acidic proteins of the nucleus, which vary in amount and composition in different cell types and which stimulate[7–10] and modify[11] the synthesis of RNA in isolated chromatin fractions.

If selectivity in transcription depends on non-histone proteins associated with DNA, one would expect changes in the distribution or metabolism of such proteins to occur at times of gene activation and repression. High rates of synthesis and "turnover" are characteristic of many of the non-histone proteins of chromatin[11–13]. The content of acidic chromosomal proteins is high in metabolically active tissues[14,15], and it correlates with the RNA synthetic capacities of chromatin fractions from different cell types[15] and from different regions of the nucleus[16]. Nuclear protein phosphorylation is stimulated by mitogenic agents[17], and synthesis is influenced by hormone administration[18].

We now present evidence for the specificity of the response of DNA-associated proteins during gene activation induced by steroid hormones. The enhancement of RNA synthesis in the liver which follows the administration of cortisol to adrenalectomized rats[19–21] is reflected in a specific stimulation of synthesis of a particular acidic protein of the hepatocyte nucleus. Because no corresponding response has been observed in the histones of the nucleus or in the ribosomal proteins of cortisol-treated animals[22], these findings support the view that the acidic protein fraction of the chromatin includes components which may be specifically concerned in the regulation of chromosomal activity.

The preparation of non-histone proteins is commonly based on differences in extractability, solubility and electrical charge between the acidic proteins, the histones and other components of the nucleus. For example, in early procedures, the acidic proteins were solubilized in dilute alkali after previous extraction of the histones in dilute mineral acids (see, for example, ref. 23). Alternatively, strong salt solutions have been used to dissociate nucleoprotein complexes as a first step in their fractionation[27]. The resulting mixture of histones, non-histone proteins, DNA and RNA can be resolved by a variety of techniques, including density-gradient centrifugation, selective precipitation and chromatographic or electrophoretic separations[8,24–29]. We have used a different method of extraction based on the solubilization of certain acidic chromosomal proteins in phenol (Fig. 1). In this procedure, the acidic proteins are extracted from the residue which remains after removal of the histones (and some other protein fractions) from isolated rat liver chromatin. The method is a modification of the procedure developed by Vinuela, Algranati and Ochoa[30] for the solubilization and electrophoretic analysis of proteins associated with the nucleic acids of bacterial viruses.

The acidic proteins were prepared from rat liver nuclei isolated in 0·025 M citric acid (a method which has also been applied to nuclei isolated in 2·2 M sucrose solutions). The nuclei were washed with buffered saline (0·15 M NaCl–0·01 M Tris-HCl; *p*H 7·5) to remove soluble proteins, and dispersed by homogenization in distilled water. Adjustment of the salt concentration to 0·15 M NaCl precipitated the chromatin, which was again dispersed in water and precipitated as before. The chromatin pellet was extracted with 0·20 M HCl at 0° C for 1 h to remove the histones, and the residue was resuspended at *p*H 8·4 and treated with phenol as shown in Fig. 1. Subsequent treatments bring the phenol-soluble proteins back into aqueous solution to permit their electrophoretic analysis.

Soluble acidic chromosomal SDS-protein

Fig. 1. Procedure for the preparation of nuclear acidic proteins from isolated rat liver chromatin.

Components of the acidic protein fraction differ in their electrophoretic mobility and can be separated and characterized as individual bands on polyacrylamide gels. We have separated complexes of the proteins with sodium dodecyl sulphate (SDS)[31]. In these conditions, the dis-

tance of migration of individual proteins can be correlated with their molecular weights[32,33], as indicated in the upper curve of Fig. 2.

The phenol-soluble proteins of rat liver chromatin separate into eleven to sixteen principal bands on electrophoresis in 10 per cent acrylamide gels at *p*H 7·2 (Fig. 2). (By modified techniques, resolution has recently been improved to yield about thirty distinct bands arranged in a pattern which is highly reproducible and characteristic of the tissue of origin: unpublished experiments of C. S. Teng and V. G. A.) Estimates of the molecular weights of the proteins in different regions of the gel were based on comparison with the migration distances of standards of known molecular weight. Light (23,500) and heavy (51,000) chains of human γ-globulin (donated by Dr Myron Waxdal) were labelled with iodine-125 (ref. 34) and reduced and alkylated as described by Shapiro and Maizel[35]. The iodinated proteins were added to the nuclear acidic protein fraction and co-electrophoresed as described in Fig. 2. The position of ^{125}I in the gel marked the location of the standards, and permitted the calculation of the relationship between mobility and distance shown in the upper curve of Fig. 2.

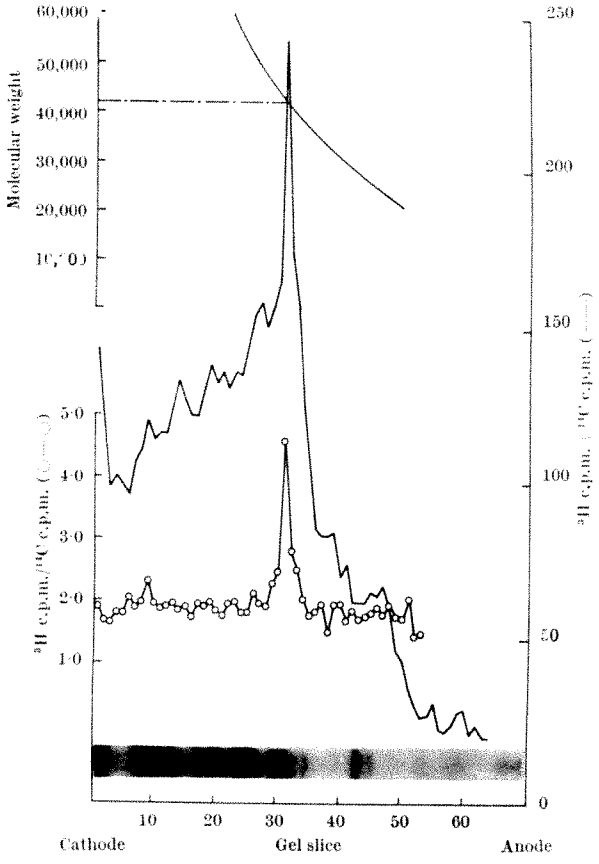

Fig. 2. Electrophoretic separation and analysis of labelling patterns for nuclear acidic proteins from livers of cortisol-treated and control rats. Matched pairs of adrenalectomized rats (180–220 g) were fasted for 20 h before administration of hormone. Hydrocortisone sodium succinate (solution Cortef, Upjohn; 20 mg) was injected intraperitoneally into two rats; a control pair received isotonic saline at the same time. At selected times, the hormone-treated animals were pulse-labelled for 1 h periods by the injection of 600 μCi of DL-4,5-^{3}H-leucine (specific activity 5 Ci/mmole). The control animals received 83 μCi of uniformly labelled L-^{14}C-leucine (specific activity: 0·28 mCi/mmole) in the same conditions. At the end of the 1 h labelling periods, the livers were removed from all animals for isolation of the chromatin and preparation of the phenol-soluble proteins. The livers from both hormone-treated and control animals were pooled, and all were homogenized together in 0·025 M citric acid. The nuclei were isolated and chromatin was prepared as described. This procedure ensured that the ^{3}H-labelled acidic proteins from the cortisol-treated animals and the ^{14}C-labelled proteins from the control animals were exposed to the same conditions throughout the course of their isolation as in Fig. 1. The mixed proteins (250 μg) from control and hormone-stimulated animals (7–8 h after cortisol injection) were co-electrophoresed on 10 per cent polyacrylamide gels with a running buffer of 0·1 M sodium phosphate (*p*H 7·2) containing 0·1 per cent SDS. The protein bands were fixed in 20 per cent sulphosalicylic acid and located by staining with Coumassie brilliant blue. Radioactivity in individual bands was determined by transverse slicing of the gel and scintillation spectrometry. Lower curve: ratio of $^3H/^{14}C$ incorporation into the acidic proteins at different positions in the gel. Middle curve: total radioactivity at different regions of the gel. Upper curve: relationship between mobility and molecular weight.

Table 1. AMINO-ACID COMPOSITION OF ACIDIC PROTEINS FROM RAT LIVER CHROMATIN

Amino-acid	Moles per 100 moles total amino-acid
Lysine	6·62
Histidine	2·25
Arginine	5·60
Aspartic acid	10·22
Threonine	4·79
Serine	5·77
Glutamic acid	13·92
Proline	5·59
Glycine	8·60
Alanine	8·08
Valine	6·35
Methionine	1·52
Isoleucine	3·98
Leucine	9·47
Tyrosine	3·08
Phenylalanine	4·10
Acidic/basic residues	1·67

Results are average values for two preparations of the phenol-soluble proteins of rat liver chromatin, not corrected for hydrolytic losses.

Amino-acid analyses of the phenol-soluble proteins of rat liver chromatin clearly indicate their acidic nature: the content of aspartic and glutamic acids greatly exceeds that of the basic amino-acids (Table 1). Chromosomal proteins prepared by the phenol procedure are also characterized by high rates of synthesis. For example, 1 h after the administration of ^{14}C-leucine, the specific activity of the nuclear phenol-soluble proteins was 9,550 c.p.m./mg, as compared with 5,450 c.p.m./mg for the cytoplasmic protein fraction and 2,640 c.p.m./mg for the acid-soluble proteins of the nucleus. Similar observations on the rapidity of ^{14}C-lysine incorporation into a phenol-soluble nuclear protein fraction were made by Steele and Busch[36].

The effects of cortisol were studied by observations on the incorporation of ^{14}C-leucine and ^{3}H-leucine into individual acidic proteins of rat liver chromatin as described in the legend to Fig. 2. The mixed acidic proteins were separated as SDS–protein complexes by polyacrylamide gel electrophoresis. The resulting pattern (Fig. 2) is a series of protein bands, each of which contains a mixture of the ^{3}H-protein from hormone-stimulated nuclei and the corresponding ^{14}C-protein from control nuclei. The total $^3H + ^{14}C$ activity of the bands is plotted as a function of the distance of migration in Fig. 2 (middle curve). The specific activities of individual proteins have not been determined in this experiment, but clearly not all bands are labelled to the same extent. A more significant analysis of the data is obtained by plotting the ratio of ^{3}H-activity to ^{14}C-activity at different positions in the gel. This ratio serves as an indication of the relative rates of synthesis of individual nuclear proteins derived from the chromatin of hormone-treated and control animals. It is plotted as a function of protein mobility in the lower curve of Fig. 2 and is remarkably uniform for all fractions in the gel except for the protein in a particular band located at gel slice 31. The rate of synthesis of this particular type of protein is specifically stimulated by cortisol administration. The extent of stimulation varies with time after administration of the hormone. It becomes evident within 2–3 h, increases at 4–5 h, and exceeds 200 per cent at 7–8 h after administration of cortisol, which is the time shown in Fig. 2.

When the administration of the isotopes was reversed—the cortisol-treated animals received ^{14}C-leucine and the control rats ^{3}H-leucine—there was a corresponding decrease in the $^3H/^{14}C$ ratio of the protein at that region of the gel which shows the specific response. The effect is not, therefore, an artefact arising from uneven quenching

or other counting anomalies which might occur at specific regions of the gel. Other control experiments have established that the proteins are nuclear in origin and are not a result of cytoplasmic contamination. For example, nuclei were isolated from non-radioactive livers in the presence of the radioactive cytoplasm from control and hormone-treated animals. The phenol-soluble proteins prepared from these nuclei had only slight ^{3}H or ^{14}C activity, and that was randomly distributed throughout the gel.

The mobility of a band in electrophoresis is a function of molecular size. According to the upper curve in Fig. 2, the acidic protein which specifically responds to cortisol has a molecular weight of 41,000. This is the first instance of such specificity in the response of nuclear acidic proteins to gene activation by steroid hormones. The function of this protein in the liver nucleus is not known.

Preliminary Experiments on the Chemistry and Pharmacology of Cannabis

by

E. W. GILL
W. D. M. PATON
R. G. PERTWEE

Department of Pharmacology,
University of Oxford

There are at least six pharmacologically effective components of cannabis. Their effects on mice include a lowering of body temperature, catalepsy, analgesia and an extension of barbiturate sleeping time, with doses from 25 to 200 mg/kg.

In this investigation we have used tincture of cannabis BPC. This is a commercial product prepared by extracting the leaves and flowers of *Cannabis sativa* with cold alcohol, evaporating the solvent and dissolving the resinous residue in fresh ethanol. The plant material is grown in Pakistan and imported into Britain under licence. The crude extract, a complex mixture[1], was fractionated according to the procedures developed by Korte and Sieper[2]. Solvent was removed *in vacuo* and the resin was extracted with petroleum spirit. This fraction, soluble in petrol, was freed from chlorophylls and carotenes by chromatography on alumina and the fraction containing phenol was purified further by counter-current distribution. Three principal fractions were obtained: (1) Δ_1-tetrahydrocannabinol (Δ_1-THC) (Fig. 1*a*; R = n-C_5H_{11}), frequently identified as the major physiologically active component, constituting 2·4 per cent of the tincture base. (2) A second single component, very similar to Δ_1-THC, which was subsequently identified as the hitherto undescribed n-propyl analogue of Δ_1-THC (Fig. 1*a*, R = n-C_3H_7). The structure of this compound was deduced from its infrared, ultraviolet, NMR and mass spectrum and has been confirmed by synthesis. The compound represented 2·0 per cent of the crude tincture base and is therefore a quantitatively significant component of the crude extract. (3) The third fraction, least mobile in the counter-current system used, was a complex mixture, characterized by strong absorption at 1,600–1,800 cm^{-1} (suggesting that it

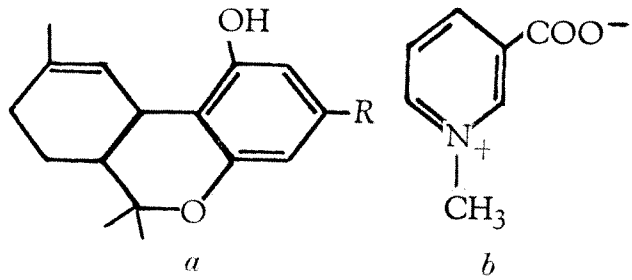

Fig. 1. Structures of (*a*) Δ_1-tetrahydrocannabinol ($R = n$-C_5H_{11}) or its n-propyl analogue ($R = n$-C_3H_7), and (*b*) trigonelline.

contained partially oxidized components), and has not been further fractionated.

The residue that was insoluble in petrol was extracted by shaking with water, and the aqueous extract was analysed by high-voltage paper electrophoresis. A strip of the paper was subjected to colour reactions, and the remainder divided into six parts and eluted.

An Atropinic Substance

We readily detected a spot with the mobility and colour reactions of trigonelline (Fig. 1*b*), a previously identified constituent of cannabis. Trigonelline was found to have little pharmacological activity, being about 10^5 times less active as an agonist than acetylcholine, and with no detectable antagonist activity. But in the eluate from this region of the strip, an acetylcholine-antagonizing material was found, with a slow course of action comparable with that of atropine, ineffective against histamine and such that the material from 1 ml. of tincture produced a fourteen-fold dose-ratio in a 5 ml. organ bath. This is equivalent to about 1 μg/g of resinous residue; but the atropine-like component is labile to acids and alkalis, and the losses, although known to occur, have not been estimated.

A second, more rapidly moving spot was also found, with an electrophoretic mobility comparable with that of the methyl or ethyl esters of trigonelline (but not that of choline). These esters are both gut stimulants; the methyl ester is like acetylcholine, but 1/200 times as potent; the ethyl ester is roughly 1/2,000 times as potent as acetylcholine, but has a flatter log-dose-response curve. Both are sensitive to lachesine but not (on the intestine) to hexamethonium. The eluate from the front of the fast spot resembled the methyl ester pharmacologically; that from the rear part had a log-dose-response curve flattened in the same way as that of the ethyl ester.

There is therefore evidence of the presence of an atropinic and two muscarinic substances in the watery extract as well as of the relatively inert trigonelline. None of these, however, has yet been obtained in sufficient quantity for chemical identification. If the ethyl ester is in fact present, it may well be an artefact resulting from esterification of trigonelline by solvent ethanol. The acetylcholine-like components could contribute to the irritant effect of the smoke. THC in a dose of 3 mg/kg was found, in the cat under chloralose, to affect neither chorda-stimulated salivary secretion nor the bradycardia in response to vagal stimulation, and it is therefore probable that the atropine-like material, rather than THC, chiefly causes the salivary and heart rate effects of taking cannabis. But because THC can reduce acetylcholine output from the parasympathetic nerve plexus of the intestine (see below), this depression of transmitter release may potentiate the atropinic action.

The chief active principles of cannabis have long been known to be insoluble in water and strongly lipophilic. The octanol : water partition ratio of THC was too high to be measured, but exceeded 500 : 1 (comparable with trichloroethylene and higher than most barbiturates). A saturated solution of THC in saline contains about 5 μg/ml. To obtain crude cannabis, THC or propyl-THC in saline solution, they were mixed with 0·5 to 2 times their weight of 'Tween 80.' Both cannabis and the pure substances act as anti-frothing agents, but none will reduce the surface-tension-lowering activity of the Tween solutions. Because we still do not know which of the pharmacologically active fractions are absorbed when cannabis is smoked or ingested, experiments were made with crude cannabis as well as with THC and propyl-THC.

Hypothermic Action

Miras[3] reported that cannabis lowers the body temperature of rats. This response, tested at an environmental temperature of 20° C, was confirmed in mice and found to be related to the dose. Intraperitoneally, 200 mg/kg produced a peak fall of 1° C. Intravenously, 12 mg/kg was ineffective, and 25 mg/kg produced in six mice a mean peak fall of 2·5° C, with recovery over a period of 30–40 min; the effect increased with increasing dosage in both magnitude (to 8° C) and duration (over 8 h). There may be peripheral factors contributing to the hypothermia, but the principal action of cannabis seems to be central. We have confirmed the observation[4] that it is effective intracerebrally. Further, it is considerably more effective by this route than when given intravenously; a dose of 25 mg/kg injected into the cerebral ventricles produced a hypothermia lasting over 8 h, with a peak fall of 6° C. It was already clear[4] that the intracerebral route was more effective than the intraperitoneal route in producing hypothermia; but this might have been the result of loss of drug during passage through the liver during absorption of the intraperitoneal dose *via* the portal vessels. The fate of any of the intracerebral injection that reaches the circulation should, however, be comparable with that of intravenously given drug. THC itself has now been shown[5] to produce hypothermia in mice when given intraperitoneally.

Because hypothermia itself both changes animal behaviour and alters physiological and pharmacological responses, so that some of the actions attributed to cannabis could have been secondary to the body temperature change, we have felt it necessary to repeat some of the previous work in conditions where significant hypothermia will not occur. All the experiments that follow, therefore, on catalepsy, analgesia and prolongation of sleeping time, were made with the mice in an environment at 30° C, known to be their thermal neutral zone (ref. 6 and unpublished work of R. G. P.).

Catalepsy

The cataleptic effect of cannabis[7] in the mouse has been developed into an objective assay, based on the proportion of time spent motionless when straddling a wire ring. Assays were four to nine point with seven to nine replications, suitably randomized. Control tests were made with 'Tween 80' solutions. Intraperitoneal or subcutaneous injections were used. All experiments were made at 30° C. Crude cannabis elicits detectable cataleptic effects at 200 mg/kg intraperitoneally or 100 mg/kg subcutaneously, and nearly maximal effect at about 500 mg/kg with duration greater than 4 h. THC was found to be active at 5 mg/kg; propyl-THC was found to be 4·8 times less active. The THC content could account for the bulk of the cataleptic effect, but comparison of the time course of action of crude cannabis with that of THC and propyl-THC suggests that propyl-THC contributes significantly to the earlier part of the response, THC itself acting relatively slowly.

If repeated daily subcutaneous doses of 100 mg/kg crude cannabis are made, the level of catalepsy achieved increases up to 8 days, indicating a cumulative effect. The recovery from the daily dose seemed faster at the end of the period than at the start. The results were reminiscent of the fat-soluble barbiturates, with which both cumulation and tolerance occur.

The cataleptic response was studied because it was an animal response which could be related to certain aspects of the human experience with cannabis. The dose required to produce the effect in mice, whether of pure THC or in terms of the THC content of the resinous residue (2·4 per cent), is roughly ten times the human effective dose when expressed per unit weight. If one compares, for a range of centrally active drugs, the doses per kilogram used to produce the characteristic actions of the drugs in mice or rats with the corresponding doses per kilogram of the pharmacopoeia, the mouse/man ratio ranges from about 2 to 100, and with some drugs the total dose for a rat is comparable with the total dose used in man. This arises, at least in part, from the more rapid turnover of drug in small animals, and is also influenced

by the route of administration and the intensity of the effect studied. So far as the doses found necessary in the experiments in this paper are concerned, therefore, there is no reason to doubt the relevance of the observations, *mutatis mutandis*, to human experience.

Analgesia

To test for analgesic action, the response to intraperitoneal injection of phenylbenzoquinone[8] was used, cannabis or other drugs being given subcutaneously; all experiments were done at an environmental temperature of 30° C. Cannabis had a threshold effect at 100 mg/kg and a marked action at 200 mg/kg. Using the same technique, 0·4 mg/kg morphine and 1·2 mg/kg chlorpromazine were approximately equivalent to 140 mg/kg cannabis resin. The results are comparable with those obtained with cannabis[9] and THC[8-11] by a variety of methods without temperature control.

We have confirmed the observation of Loewe[12] that cannabis prolongs pentobarbitone sleeping time in mice even if the experiment is made in an environmental temperature of 30° C. The effect is just detectable at 50 mg/kg intraperitoneally and increases with dose; with 200 mg/kg cannabis intraperitoneally the mean sleeping time in a group of nine mice given 50 mg/kg pentobarbitone 30 min later increased to 85 min, from a control value of 34. This prolongation was detectable 3 h after cannabis administration, but sleeping times tested 24 and 48 h after cannabis were normal, and no sign of induced enzyme activity after a single dose of cannabis was found.

It was possible that cannabis, while not itself overtly hypnotic, might potentiate barbiturate hypnosis by its own central action. A control experiment with ether which is not metabolized was therefore made. With subcutaneous injection of cannabis or 'Tween 80' control, and intraperitoneal injection of ether in olive oil, cannabis was found not to prolong ether sleeping time in a dose which prolonged pentobarbitone sleeping time. The evidence is therefore strengthened that cannabis interferes with microsomal degradation of barbiturates.

Toxicity

A preliminary study was made of the lethality of cannabis injected each day intraperitoneally at various dose levels. These experiments were made at the normal room temperature of 20° C. A single dose of 5,000 mg/kg killed all of five mice; 1,000 mg/kg killed all of four mice in 4 days; 500 mg/kg killed two of five mice in 45 days; 100 mg/kg caused no deaths in 50 days. These results imply either cumulation of the drug itself, or summation of its effects. The cause of death has not yet been analysed; but it may be noted that in cats under chloralose, THC at 2 mg/kg substantially depresses both respiration and blood pressure.

Teratogenicity in rats and hamsters[13,14] and foetal resorptions in mice[15] have been described at dose levels of 4·2–100 mg/kg daily at the appropriate stage of pregnancy.

Muscarinic and atropinic actions by water-soluble factors have been described above. The three fat-soluble fractions were tested on the guinea-pig ileum stimulated transmurally or with acetylcholine. THC, in a concentration of 1 μg/ml. upwards, was found to depress the twitch response to transmural stimulation but not the response to acetylcholine (which was sometimes potentiated). It must therefore depress acetylcholine output by the nerve endings; in this way it resembles morphine[16], catecholamines[17] and anaesthetics[18], but it differs from them in its much slower onset of effect and very delayed recovery, still incomplete after many hours. Propyl-THC has a similar action, with some initial stimulant effect, but recovery from its effects was much more rapid, and it was less active than THC. The third (uncharacterized) fraction depressed both the twitch and the response to acetylcholine and resembled a nonspecific depressant such as occurs among higher alcohols.

The fractions were also tested on the guinea-pig vas deferens stimulated by noradrenaline, by electrical stimulation with brief trains of shocks, or by stronger field stimulation with brief shocks, the latter being particularly useful in preliminary screening tests. THC and propyl-THC had no consistent effect on the response of the vas to noradrenaline. THC slightly reduced the response to field stimulation by trains of shocks. The response to strong single shocks was greatly potentiated by both THC and propyl-THC; THC was approximately three times more potent, and considerably slower in action. This response is insensitive to tetrodotoxin, and so presumably reflects a direct response of the smooth muscle to the electric field. Cocaine and some other local anaesthetics produce a similar potentiation.

Accumulation in Fat?

Cannabis thus contains, apart from THC, at least five other pharmacologically active components, three water-soluble and two fat-soluble, one of which has been identified as the propyl homologue of THC. In the water-soluble fraction, atropinic activity has been found which may be responsible for the effects of cannabis on salivary secretion and heart rate in man. This effect may be potentiated by the ability of THC to depress acetylcholine output from parasympathetic nerves.

Cannabis resin given to mice lowers body temperature by up to 8° C. Because hypothermia of this degree could change the animal's responses significantly, tests for the action of cannabis in producing catalepsy, analgesia and prolongation of barbiturate sleeping time were repeated, with the mice in their thermal neutral zone, to prevent body temperature changes. In these conditions cannabis still produces analgesia and catalepsy, and still prolongs pentobarbitone sleeping time. It was also shown that the sleeping time caused by a non-metabolized anaesthetic (ether) was not prolonged. Doses required for these effects ranged from 25 to 200 mg/kg according to route of injection. In preliminary toxicity tests the LD_{50} for a single dose lay between 1,000 and 5,000 mg/kg; for doses repeated daily it lay between 500 and 1,000 mg/kg.

Finally, in view of the report from a university survey[19] that of 153 students who had taken cannabis, 72 per cent took it daily or more often, attention should be paid to the fat-solubility of certain of the active principles of cannabis, their prolonged action, and the liability to cumulation.

This work has been supported by a grant from the Medical Research Council.

Creep and Friction of Ice

by
D. TABOR

Surface Physics,
Cavendish Laboratory,
Cambridge

The creep of polycrystalline ice in uniaxial compression has been studied over a very wide range of strain rates. The creep is far too slow to explain the friction of ice observed at very low sliding speeds, but experiments with single crystals show that sliding produces recrystallization at the interface, the ice presenting an orientation favourable to easy glide in directions tangential to the interface.

BARNES[1,2] has described experiments carried out in our laboratory on the indentation of ice using spherical and conical indenters. At temperatures above about $-3°$ C the indentation pressure was sufficient to produce appreciable pressure melting. With colder ice, although the indentation pressure was higher, pressure melting was no longer possible and the indentation process was essentially one of plastic flow. The hardness could be correlated with the yield stress of the ice in exactly the same way as for metals[3]. In particular it was found that the indentation hardness decreased with loading time due to the creep of the ice. Indeed, an analysis correlating the high temperature creep of metals, oxides and carbides with their hardness behaviour was found to be applicable to the hardness and creep properties of ice at temperatures above $-50°$ C.

Creep of Ice

Recently we have extended that study of the creep properties of ice to a much wider range of strain rates and temperatures, although in here we describe only the behaviour of ice above about $-10°$ C. The ice was polycrystalline (grain size about 1 mm) and was prepared from distilled water. A cylindrical specimen was subjected to compression between hard platens which were pressed together under a constant load. Because the total deformation was not large (≤ 5 per cent) this is very close to conditions of constant stress. The rate of approach of the platens was observed and from this the total strain determined at any time after the load was applied. The general behaviour is shown in curve II, Fig. 1. The portion OA is the instantaneous strain ε_0 which occurs when the load is first applied, AB the region of transient creep, BC the region of secondary or viscous creep and CD the region of tertiary creep. Similar characteristics are observed with metals and other solids. With metals examined under tension, tertiary creep is largely associated with the formation of intergranular fractures produced by triaxial tensile stresses. In compression tests such a mechanism can scarcely apply and the behaviour must be caused by other processes. With ice in our experiments, when the applied stress is compressive, tertiary creep is due primarily to recrystallization of the ice in an orientation favourable to easy glide[4]. This recrystallization is clearly visible in polarized light. At high stresses the secondary creep BC becomes increasingly shortened until the transient creep appears to be immediately followed by tertiary creep (curve I), whereas at low stresses the creep behaviour is still dominated by transient processes during the time available for an experiment (up to 100 days) and secondary creep is never established (curve III). The creep rate depends on the part of the creep curve chosen and so the simplest quantity to study is the minimum creep rate which can be deduced from the point of inflexion in curve I, from the secondary creep rate in curve II and from the final creep rate in curve III. Fig. 2 shows results obtained in this way for polycrystalline ice at $-2°$ and $-8°$ C over a wide range of strain rates: here the minimum observed creep rate $\dot{\varepsilon}$ is plotted against compressive stress σ on log–log ordinates. We shall show that the marked curvature at low stresses is due to the dominance of transient creep.

Over the whole range OABC the behaviour at any given stress may be accurately described by a typical creep equation of the form

$$\varepsilon = \varepsilon_0 + \alpha t^{1/3} + \dot{\varepsilon}_s t \qquad (1)$$

where ε_0 is the instantaneous strain, ε the total strain after time t, and α a suitable constant. The term $\alpha t^{1/3}$

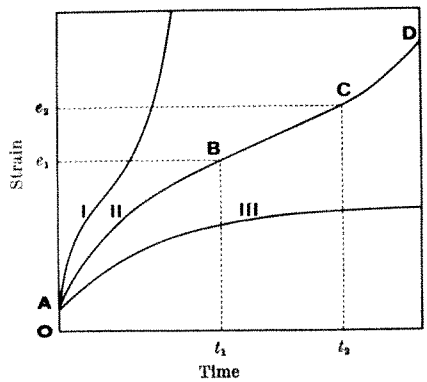

Fig. 1. The creep of ice under constant load at various levels of stress.

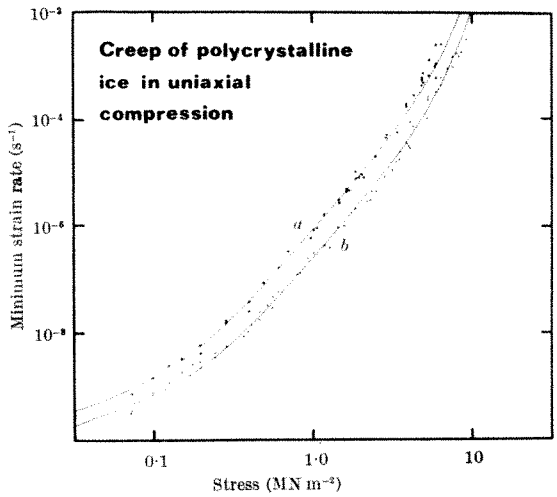

Fig. 2. The variation of the minimum creep rate $\dot{\varepsilon}$ with stress σ. *a*, $-2°$ C; *b*, $-8°$ C.

describes the transient creep and $\dot{\varepsilon}_s t$ the secondary or viscous creep. If now we analyse the behaviour in terms of equation (1) we may extract the true secondary creep from the data even when viscous creep seems to be completely overtaken by recrystallization and tertiary creep. At very high stresses this analysis is restricted to the early portion of the creep curve where the observed points are randomly distributed about the curve derived from that equation; at large strains dynamic recrystallization enhances the creep rate and this is always greater than that predicted. Unfortunately it is not possible to analyse every creep curve in this manner because in our earliest experiments insufficient attention was paid to obtaining data at small strains when in transient creep. The results for secondary creep are shown in Fig. 3. There is now no curvature at low stresses.

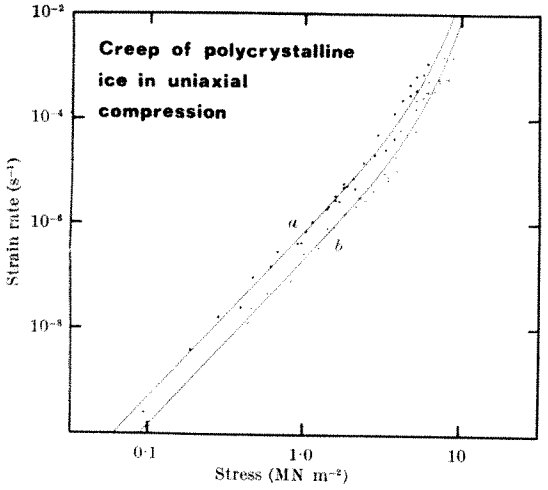

Fig. 3. The variation of the secondary creep rate $\dot{\varepsilon}_s$ with stress σ. *a*, −2° C; *b*, −8° C.

The secondary creep rate $\dot{\varepsilon}_s$ may be described by a relation of the form

$$\dot{\varepsilon}_s = A\sigma^n \exp(-Q/RT) \qquad (2)$$

over a limited range of stress where σ is the applied stress, n a constant of order 3 or 4, Q an activation energy. Clearly if $\dot{\varepsilon}_s$ were simply a function of σ^n these plots should give straight lines of slope n and the gap between such plots at different temperatures should provide a measure of the activation energy. At low stresses the slopes are indeed of order 3, and the calculated activation energy is of the order of 120 kJ mol^{-1}. At higher stresses the slope increases such that at stresses of the order of 10 MN m^{-2} the apparent slope is about 5 and Q is still about 120 kJ mol^{-1}. In fact, it turns out that expressing the viscous creep in terms of equation (2) can be misleading. Over the whole stress range a single relation of the form

$$\dot{\varepsilon}_s = A'(\sin h\alpha\sigma)^n \exp(-Q/RT) \qquad (3)$$

holds. It is only when we attempt to describe a portion of it in the form of equation (2) that n, the power of σ, appears to change. Indentation hardness measurements again show a correlation with these creep data, the stress level generally corresponding to that part of the creep curve where the value of n is of order 4–5. A fuller description of these results and a discussion of the creep processes will be published elsewhere.

Slow Speed Friction of Polycrystalline Ice

The friction of ice sliding on a flat surface has been studied using the apparatus designed by Barnes[6]; this is housed within a large refrigerator kept at temperatures constant to within 0·1° C. The sliding speed could be varied from 10^{-8} to 10^{-1} ms^{-1}. The slider which was polycrystalline ice in the form of a cone of included angle of 170° was pressed on to the lower surface under a normal load of either 32 or 78 kg. The tip wore away and after a few traversals of the lower surface the cone acquired a flat contact region (about 5–10 mm diameter) which continued to grow by creep and wear, but very much more slowly. A consequence of the large included angle is that the deformation within the ice is confined to a zone close to the interface where the shear stresses are very much greater.

Fig. 4 shows the dependence of the coefficient of friction on sliding speed at −11·7° C. It is seen that the maximum friction for ice on rock (peak to valley roughnesses of about 1·5 μm) is large (about 0·9) and approximately constant for sliding speeds between 10^{-6} and 10^{-4} ms^{-1} (region BC). Slip stick occurs at all speeds above 10^{-6} ms^{-1}. At higher speeds the coefficient of friction diminishes rapidly to a value of 0·05 or less (region CD). At lower speeds there is also a slight fall in friction (region AB). By way of contrast, when ice slides on a steel surface of comparable roughness the friction remains low over a wide speed range and the evidence suggests that this is due to poor adhesion at the interface.

Simple calculations of heat flow[6] show that for ice sliding on rock (sliding speed 10^{-2} ms^{-1}, contact zone 100 mm in diameter, frictional force 10 kg corresponding to $\mu = 0{\cdot}3$) the temperature rise of the interface is of the order of 15° C. It is sufficient to produce some surface melting and this presumably accounts for the observed drop in friction as suggested by Bowden and Hughes[7] many years ago. With ice sliding on a metal surface the corresponding effect would only be expected at sliding speeds of 10^{-1} ms^{-1} or more.

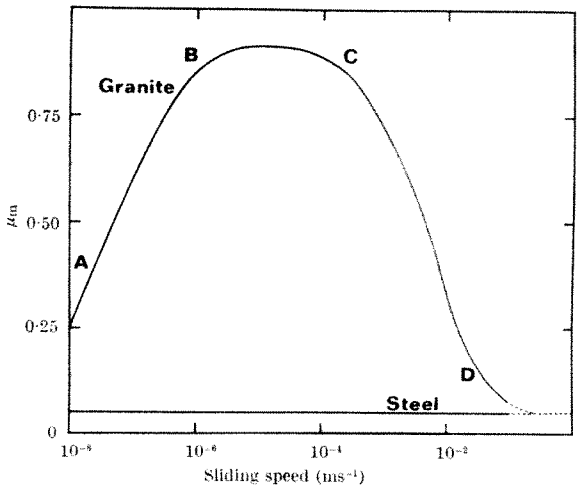

Fig. 4. The friction of ice at −11·7° C on granite and on steel. Each curve is derived from approximately fifty individual measurements. The experimental scatter is ±10 per cent. The granite was a coarse-grained quartz–feldspar–biotite–muscovite granite from the Correnie quarries, Alford, Aberdeenshire.

The most interesting feature of the friction of ice on rock is the region AB (Fig. 4). There is other evidence to show that there is strong interfacial adhesion between the ice and the rock so that shearing apparently occurs within the ice itself. We should therefore be able to explain the tangential force necessary to produce sliding in terms of the creep properties of ice itself. If, however, the creep characteristics of ice described in Fig. 3 are used, it is found that the observed tangential stresses are too small and shear would have to occur over an unrealistic thickness of ice of the order of 10^{-2} m. This problem was first recognized by Barnes in his preliminary friction measurements. For this reason he suggested the presence of a

viscous liquid film at the interface*. This seems unacceptable for temperatures much below 0° C. An alternative is to take into account the effect of the combined normal and tangential stresses in calculating the creep rate at the interface. We assume that about four-fifths of the normal contact pressure is in the form of a hydrostatic component[10] so that only about one-fifth of the pressure plays its part as a shear stress in facilitating creep When μ is small this deviatoric component of the normal load appears to the power $(n-1)$ in the combined stress creep equation so that it does, in fact, greatly increase the calculated tangential creep rate. It would, however, also be accompanied by marked creep in the vertical direction whereas this is not observed. One way of explaining away this difficulty is to assume that contact occurs only at discrete asperities continuously reformed during sliding so that the true stresses are higher. This assumption is unattractive, for if the cone is deliberately worn to give a larger geometric area of contact the friction over the region AB increases roughly in the same proportion.

Most of these difficulties are resolved if experiments are carried out with an ice slider made of a single crystal of ice.

Friction of Single Crystals of Ice

A single crystal of ice was cut into conical form with its c axis normal to the cone axis and therefore parallel to the direction of sliding. This was slid over a granite surface. After a few repeated traversals a flat was worn on the cone as with the polycrystalline specimen. The frictional behaviour was the same as that shown by polycrystalline specimens. If, however, the ice specimen was examined in polarized light, it was found that the surface layers of the ice had recrystallized to a depth of about 0·2 mm and that all the surface crystallites were oriented with the c axis normal to the sliding interface, that is all the crystallites were in the direction of easy glide relative to the interface. The situation resembles that of tertiary creep shown in Fig. 1. It is not possible from our creep data to quantify the creep behaviour in this regime. Our own measurements and those of other workers[4,11] indicate, however, that creep in this direction is about 100 times easier than when ice is in other orientations. These results suggest that in those experiments where there is good adhesion between the ice and the substrate the friction at low sliding speeds is determined by the force required to produce creep within a very thin layer of ice close to the interface: as a result of recrystallization this layer develops an orientation favourable to easy shear tangential to the surface. This layer is also unfavourably oriented for creep in a direction normal to the interface so the normal stress does not produce appreciable creep in this direction.

These results have a direct bearing on the creep of glaciers. They also suggest that similar processes may be involved in the sliding, at high temperatures and for protracted periods, of hexagonal metals. Evidence for this is provided by the experiments of Buckley[12].

We thank the director of the Scott Polar Research Institute, Cambridge, for the use of the cold laboratories for the creep experiments, and Mr M. Badcock for help with polishing the granite surface. One of us (J. C. F. W.) was a recipient of a Natural Environment Research Council grant.

* An important paper on the adhesive properties of ice by Jellinek[8,9] seemed to support this hypothesis. He measured the adhesive strength in shear and in tension of thin disks of ice frozen between metal or polymeric platens. The adhesion in shear was far less than in tension and he attributed this to the presence of a thin liquid-like amorphous layer with properties intermediate between those of ice and water. If such a film is present it is easy to show that viscous forces resisting shear will be far smaller than those resisting tension. However, his results can be explained much more simply without invoking the liquid film if the contribution of friction between the platen and the ice is considered. If Y_0 is the unlaxial plastic yield stress of bulk ice in frictionless tension or compression experiments the yield stress Y, both in tension and compression, for ice between rigid platens will be given by

$$Y = Y_0(1+\mu a/h) \quad (4)$$

where μ is the coefficient of friction at the platens, and a/h the ratio of the specimen width to height. Jellinek used disk shaped specimens for which a/h varied from about 1 to 20 and the observed tensile yield stress for steel platens was found to lie between 1 and 7 MN m^{-2}. His data fit equation (4) extremely well. A simple derivation of this equation together with a more detailed discussion is to be found in ref. 10; pp. 37–40. It is true that a transition layer a few molecules thick may well exist at temperatures closer to 0° C and we do not wish to dispute this. Our main point is that our low-speed friction results may be explained without invoking the presence of such a film.

E. J. WILLIAMSON
Clarendon Laboratory, Oxford

This article describes the temperature profiles through the atmosphere that are being obtained from the radiometer on Nimbus 4.

Ways in which radiometric measurements from satellites can give information about the atmosphere have recently attracted a great deal of attention. In 1959 Kaplan[1] suggested that temperature could be inferred from the emission from the ν_2 vibration of carbon dioxide centred at a wavelength of 15 μm in the infrared. These measurements were first carried out on the Nimbus 3 satellite launched in April 1969, which included a 7-channel grating spectrometer and a Michelson interferometer. Nimbus 3 showed clearly that the temperature structure in the atmosphere up to 30 km altitude can be measured with an accuracy such that the error in the mean temperature of layers 200 mbar thick is less than 2° C in clear conditions[2,3].

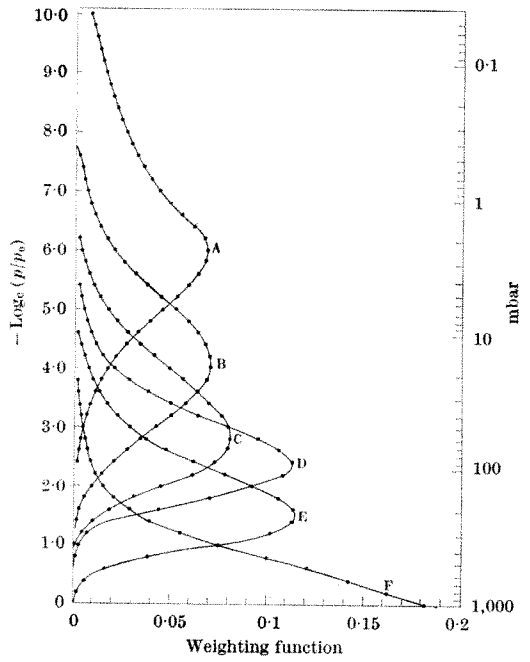

Fig. 1. Weighting functions for the six channels plotted against pressure as the vertical coordinate.

The development work on the selective chopper radiometer, which is a vertical temperature sounder for the Nimbus 4 satellite, began in 1961. An original feature is the simultaneous observation by interference techniques of a large number of individual lines in the CO_2 spectrum first considered by Houghton[4] and Smith[5], and finally achieved by selective chopping using CO_2 filled cells[6]. The instrument combines "coarse" resolution by interference filters (from 3·5 to 10 cm^{-1} bandwidth) with "fine" resolution within the bandwidth achieved by selective chopping or absorption by a cell of CO_2 (ref. 7).

The use of the CO_2 cells in absorption (channels C, D, E and F) selects wavelengths at which the absorption coefficient of CO_2 is relatively constant within each channel and has the effect of improving the vertical resolution of the instrument. The "selectively chopped" channels (A and B) pick out the line centres and allow radiation to be received from considerably higher altitudes than is otherwise possible. A second advantage is that this method of selection of a uniform absorption coefficient enables sufficient energy to be collected for adequate radiometric accuracy. In fact the integrated spectral bandwidth of the radiometer is rather greater than that of spectrometers. The design freedom thus created is used to make a radiometer of convenient size for use on satellites. The instrument is fully described by Houghton and Smith[8] and Abel *et al.*[9].

For an infinitely deep atmosphere which is horizontally stratified, the intensity of radiation energy I emitted vertically upwards in one of the spectral channels of the radiometer may be written

$$I = \int B(T)\, K(y)\, dy \qquad (1)$$

where $B(T)$ is the Planck function appropriate to the wavelength of the interval and T is the atmospheric temperature at the level where the pressure is p. The quantity I when in units of energy per unit time per unit spectral interval per unit area per unit solid angle is known as the radiance. The parameter $y = -\log p$ is chosen as the dependent variable for reasons of convenience. The weighting function $K(y)$ is dependent on the characteristics of carbon dioxide in the spectral interval appropriate to a particular channel. For the purposes of numerical computation, equation (1) may be written as

$$I = \sum_i B(T_i)\, K(y_i)\, \Delta y$$

The values of $K(y_1)$ for the six channels are plotted in Fig. 1 where the discrete values at different levels belonging to a given channel have been joined together.

The Nimbus 4 satellite was launched on April 8, 1970, into a polar Sun-synchronous orbit of about 1,100 km altitude. The selective chopper radiometer was switched on at the beginning of the sixth orbit and has worked

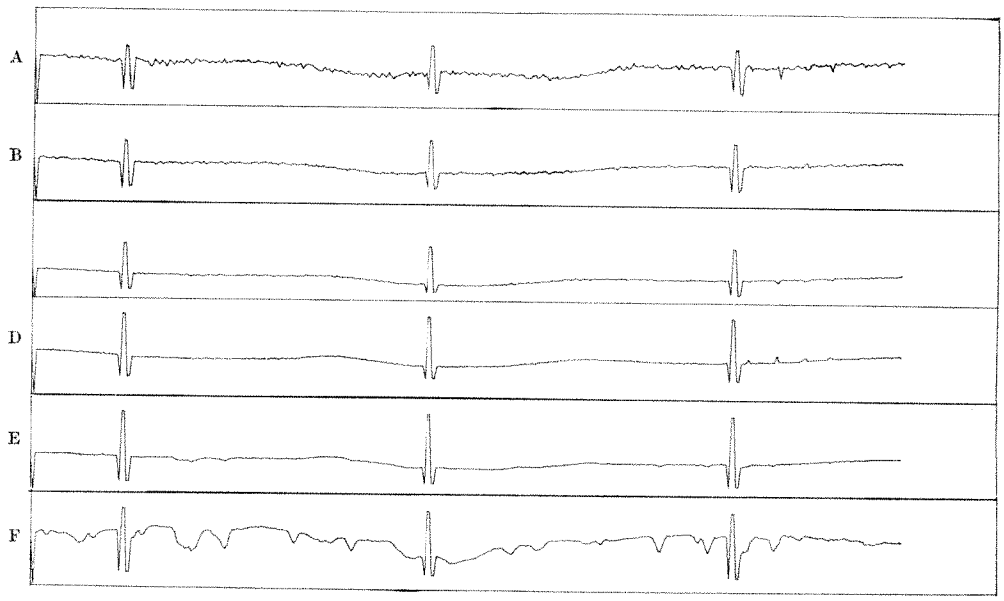

Fig. 2. Plot of signals received (averaged over 16 s) from the six channels for one complete orbit on June 22, 1970. The channel numbers are shown on the left. Calibration sequences occur three times during the orbit. In these sequences the largest signal is from a black body at instrument temperature (about 290 K) and the smallest signal corresponds to zero radiation from space.

completely satisfactorily from the start. Data are transmitted in near real time over a data link from Washington DC to Oxford and Reading. Initial processing is carried out on the data immediately they are received so that the results are plotted within about one day of the measurements being made. Figs. 2 to 6 show various presentations of the results which are being carried out on a routine basis.

Fig. 2 shows the signals from the six radiometer channels for one orbit. Fig. 3 shows a temperature profile computed from the six radiances using the inversion method described by Rodgers[10], compared with a radiosonde and a rocketsonde launched almost at the same time as the passage of Nimbus 4 over Wallops Island. In this comparison, which is for a clear atmosphere, no adjustment of the weighting function $K(y)$ has been made in order to have a good match with the radiosonde or the rocketsonde. The weighting functions appropriate to the different channels have been deduced from laboratory measurements combined with calculations based on the carbon dioxide spectrum. It can be seen that there seems to be satisfactory agreement apart from the region of channel B where systematic differences of about 5° C between the rocketsonde temperatures and those deduced from the radiances have been noticed.

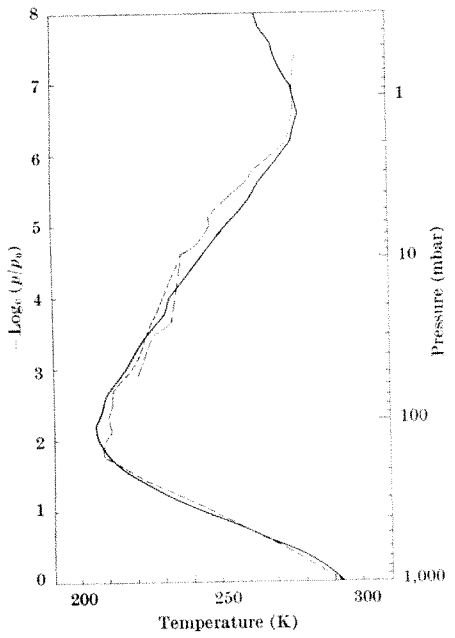

Fig. 3. Comparison between temperature profile deduced from the radiances (full line) over Wallops Island June 17, 1970, at 1644 Z, radiosonde from Wallops Island June 17, 1970, at 0000 Z and rocketsonde from Wallops Island June 17, 1970, at 1630 Z.

Fig. 4 shows a mean meridional profile of the atmospheric temperature in which the radiances inverted as described by Rodgers[10] are averaged over latitude circles for a period of one day, and plotted out as a cross-section. In Fig. 5 the radiances in channels A and B are plotted for one particular day. The orbits over which data were collected are shown in Fig. 6. The upper stratosphere over the north pole is warm at this time of year with a small gradient of temperature from the warm pole to the colder equator. The upper stratosphere near the south pole is cold. The most interesting feature of the maps is that whereas the isopleths for channel B are nearly circular and circumpolar, for channel A the coldest region is not at the pole and there is considerable structure in the pattern of isopleths. Substantial changes occur in this pattern with time which are reflected to only a small extent in channel B. Instrumental causes for these changes can be ruled out because overlapping observations

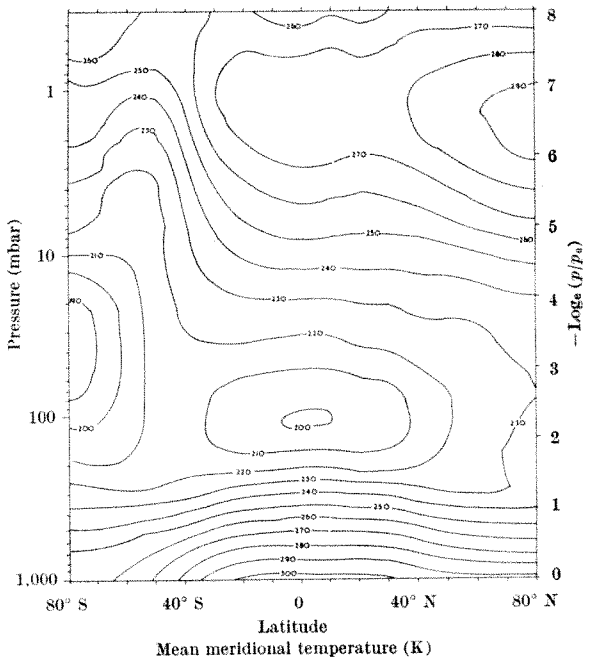

Fig. 4. Mean cross-section of the atmosphere from 80° N to 80° S for June 22, 1907.

from different orbits are usually consistent and day to day changes can be followed in a sensible way.

The vertical resolution of the radiometer is clearly demonstrated by examining the signals from channels E and F in Fig. 2. The irregular dips in channel F (centred at 5 km height (see Fig. 1)) arise when the radiometer views cloud radiating essentially as a black body at a temperature depending on the height of the cloud top. In the next highest channel E (centre 10 km) very little of these effects can be seen showing that this channel is not sensitive to radiation at the level of most cloud tops. Estimates have been made from data from a number of orbits of the proportion of time that the signals in different channels are noticeably affected by cloud. These estimates are about 50 per cent for the ground channel (G)*, about 40 per cent for channel F (centred at 5 km) and only about 3 per cent for channel E (centred at 10 km).

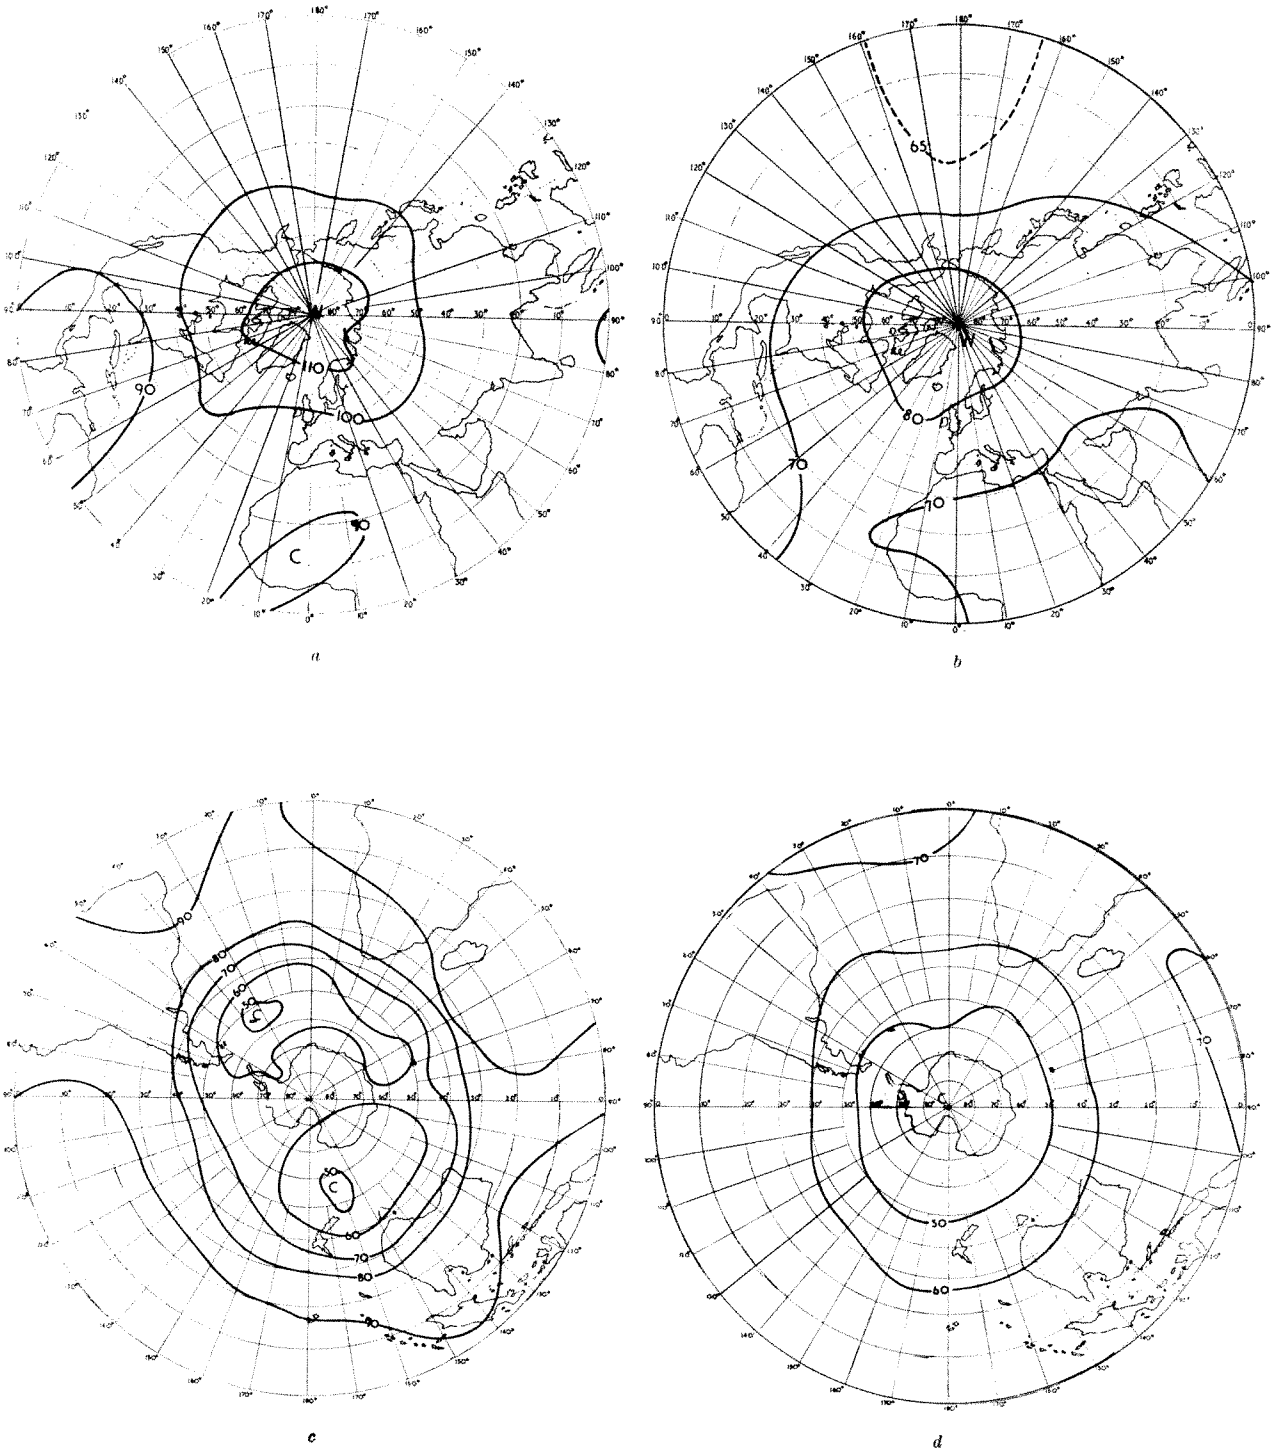
Table 1. ACCURACY OF TEMPERATURE MEASUREMENT

Channel	A	B	C	D	E	F	G
Representative viewing temperature (K)	250	240	230	220	240	270–210	300–220
Viewing time for 1 K r.m.s. noise (s)	60	25	7	3	1	1	1
No. of independent measurements per orbit	100	250	900	2,400	6,400	6,400	6,400

Finally, Table 1 summarizes the observed accuracy of the temperature measurements by showing the integration times necessary to achieve an r.m.s. noise temperatures of 1 K.

We thank the teams at Oxford and Reading Universities for their enthusiasm, Professor P. A. Sheppard and Dr G. D. Robinson for encouragement, and the staff of the Science Research Council led by Mr J. F. Hosie for their cooperation. Dr J. B. Thompson and Messrs. C. I. Wilson, R. Sandwell and J. Whitney of Elliott Bros., who manufactured the radiometer, and Messrs H. A. McLeod and F. Ritchie, of Grubb Parsons, who manufactured the filters, helped in many ways. We also thank the staff of the Nimbus Project, NASA, for cooperation, particularly

* This channel, which is in the atmospheric window near 11 μm, can be switched in instead of channel C on command.



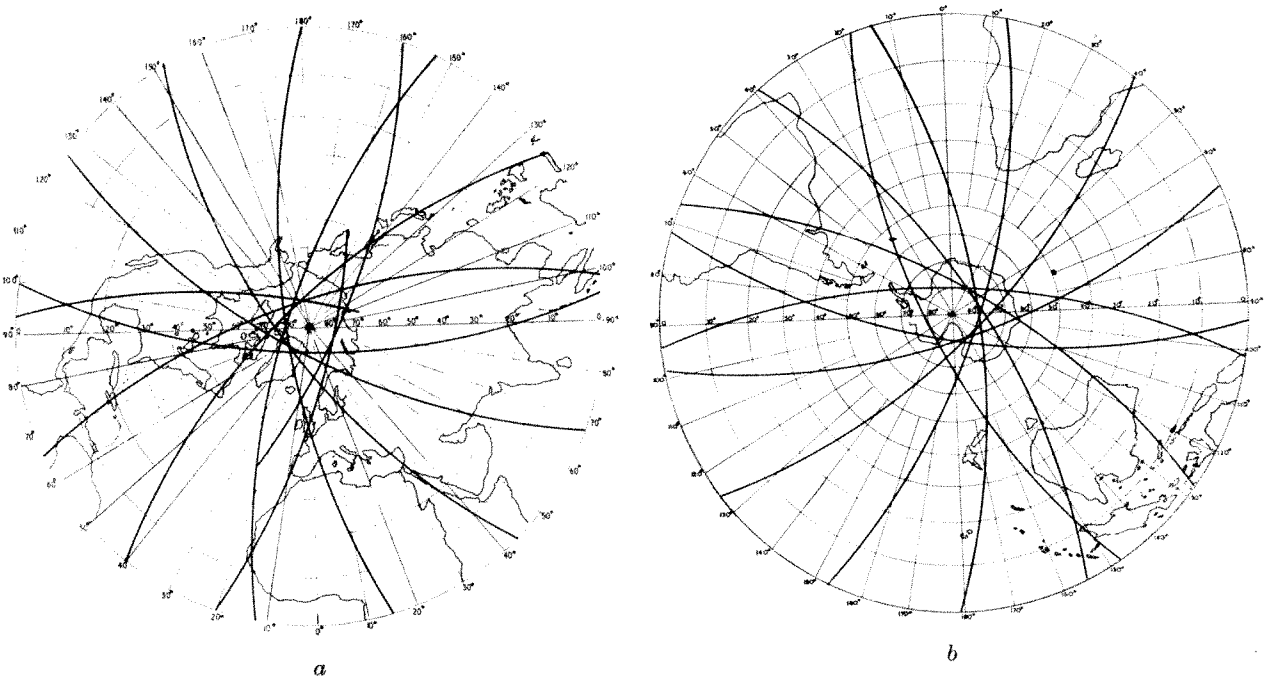


Fig. 5. Maps showing isopleths of radiances in channels A and B. The units of radiance are mW m^{-2} s^{-1}. The equivalent temperatures of a black body which would give the same radiance are:

Radiance	Equivalent temperature (K)
50	224·7
60	235·5
70	243·6
80	251·9
90	259·8
100	267·8
110	274·2

W and C show warm and cold areas respectively. All the maps are for June 22, 1970. *a*, N hemisphere channel A; *b*, N hemisphere channel B; *c*, S hemisphere channel A; *d*, S hemisphere channel B.

a *b*

Thermal Emission Spectra of the Earth and Atmosphere from the Nimbus 4 Michelson Interferometer Experiment

by
R. A. HANEL
B. J. CONRATH
Goddard Space Flight Center,
Greenbelt, Maryland

Profiles of atmospheric temperature, humidity and ozone can be recovered from the thermal emission spectra in the interval 400 to 1,500 cm^{-1} obtained from the Nimbus 4 satellite. The spectra can also be used to study surface restrahlen effects and other geophysical and meteorological phenomena.

THE meteorological research satellite Nimbus 4, launched on April 8, 1970, into a circular polar orbit of 1,100 km altitude, carried, among other instruments, a Michelson interferometer similar to the one placed in orbit by Nimbus 3 approximately a year earlier[1]. The infrared emission spectra of the Earth and its atmosphere recorded by Nimbus 4 are better than the earlier results. Instrumental improvements include (1) a higher spectral resolution equivalent to 2·8 cm^{-1} compared with 5 cm^{-1}, (2) a narrower field of view of 5° compared with 8°, and (3) a lower noise equivalent radiance, particularly noticeable at the higher wave number end of the spectrum. The upper wave number limit was chosen at 1,500 cm^{-1} (6·7 μm), in part to permit the higher spectral resolution without a change in the data interface to the Nimbus spacecraft. The lower limit of 400 cm^{-1} (25 μm) for the recorded spectral range is the same as on Nimbus 3.

The scientific objectives of this experiment are similar to those of the earlier IRIS experiment, that is, the vertical soundings of atmospheric temperatures, humidities and ozone concentrations. The recording of the complete spectrum between 400 and 1,500 cm^{-1} has also permitted other scientific investigations, studies of surface conditions[2] for example. In the first IRIS experiment, the demonstration of the principles of atmospheric soundings of temperature and composition was emphasized. Application of the large body of data to circulation studies and other meteorological tasks is now beginning. The higher spectral and spatial resolution and better signal-to-noise ratio of the Nimbus 4 interferometer will permit considerable refinements in these techniques.

Fig. 1 shows three spectra selected from the Nimbus 4 data to illustrate their quality and usefulness. Included are the coldest spectrum and the warmest spectrum

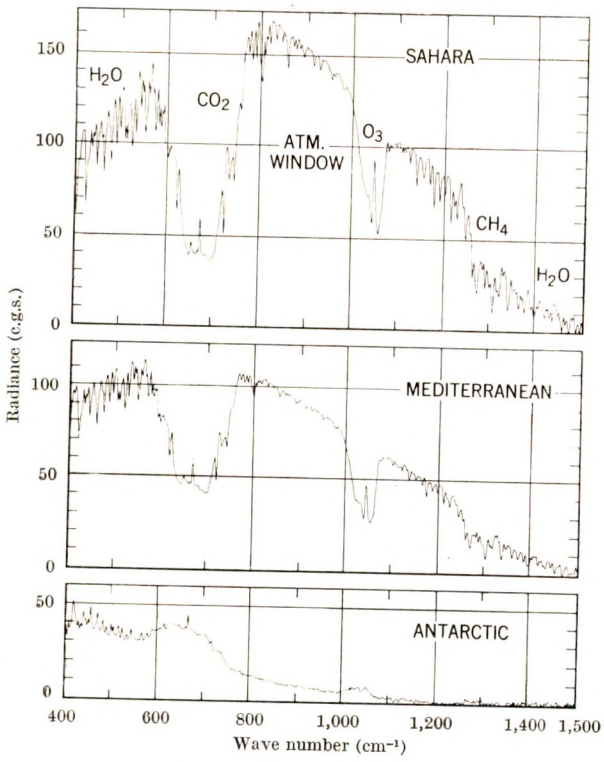

Fig. 1. Selected spectra obtained with the Michelson interferometer flown on the Nimbus 4 satellite. The three spectra shown here, obtained over the Sahara Desert, the Mediterranean and the Antarctic, are apodized, resulting in a resolution equivalent to 2·8 cm⁻¹. Atmospheric constituents responsible for the various absorption features are indicated in the upper spectrum.

recorded on orbit 29 (April 10, 1970), along with a mid-latitude case taken over the Mediterranean. Each spectrum is computed from a single interferogram recorded by the instrument within a 13-second interval. The instrumental technique used and the on-board calibration procedures are discussed elsewhere[3].

The spectra of Fig. 1 were processed using an apodization or smoothing function to reduce the side lobes of the instrument function, and the same spectra are shown in Fig. 2 without smoothing. The spectral resolution in this case is almost twice as high, corresponding to about 1·5 cm⁻¹. When the data are processed in this way, the instrument function has more pronounced side lobes, so the apodized spectrum is preferred for a radiometric analysis such as that required in obtaining atmospheric temperature profiles. For line identification, however, the higher resolution of the unapodized spectrum has a distinct advantage.

The warmest spectrum of the three shown in Figs. 1 and 2 was recorded over the Sahara Desert. The field of view of the instrument covering a circular area 100 km in diameter has been superimposed on a television picture (Fig. 3) taken by the Nimbus Image Dissector Camera System at the same time. The data show the features of CO_2, H_2O, O_3 and CH_4 as indicated in Fig. 1. The effects of the residual ray phenomenon (restrahlen) originating from the SiO_2 in the surface result in brightness temperatures approximately 10 K lower in the window region on the high wave number side of the 1,042 cm⁻¹ (9·6 μm) ozone band than those on the low wave number side. The maximum brightness temperature of 320 K (47° C) in the atmospheric window is consistent with a poor heat conducting material at the surface, such as dry sand.

The Mediterranean spectrum was recorded shortly thereafter. The maximum brightness temperature of 285 K (12° C) is close to the water surface temperature. The coolest spectrum recorded over the Antarctic plateau indicates a surface temperature of 190 K (−83° C). The CO_2, O_3 and H_2O features appear in emission, indicating a warmer atmosphere above a colder surface. The inferred surface temperature is extremely low,

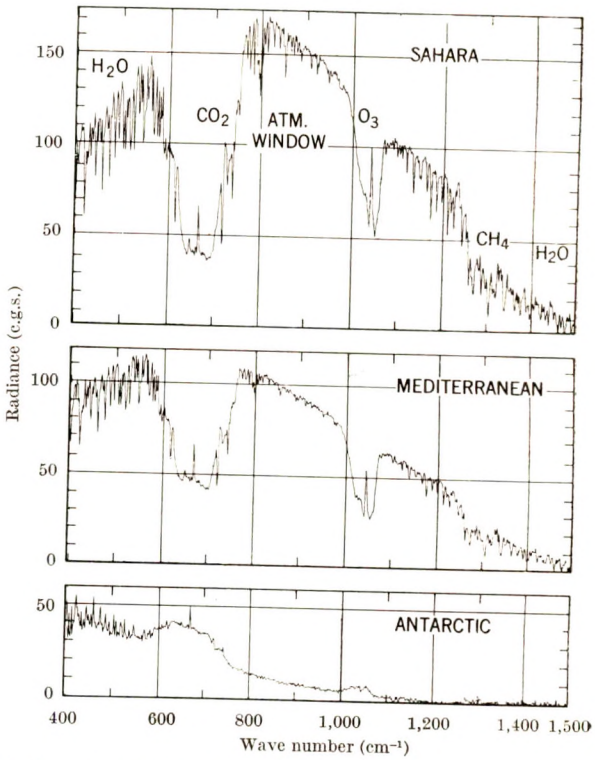

Fig. 2. The same spectra as shown in Fig. 1 are given here in their unapodized form with a resolution equivalent to 1·5 cm⁻¹.

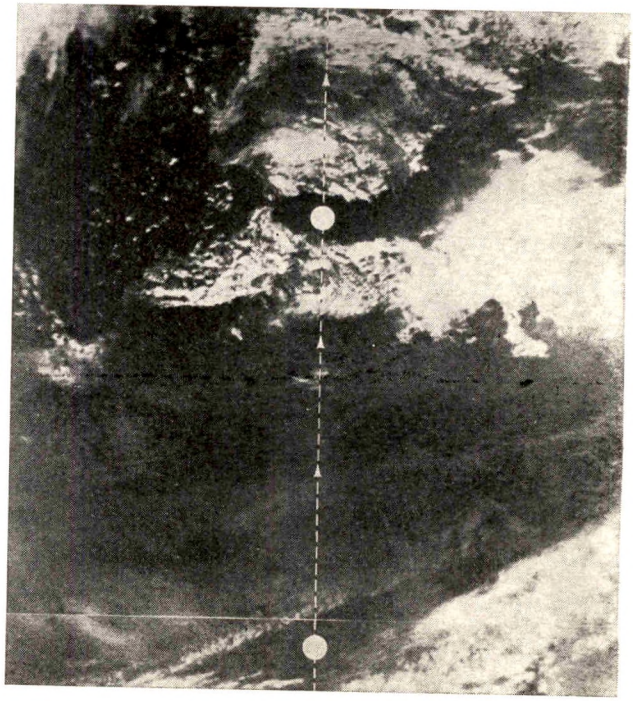

Fig. 3. Television picture obtained from the Nimbus 4 satellite. The fields of view of the Michelson interferometer, corresponding to the Sahara and Mediterranean spectra, given in Figs. 1 and 2, are indicated by the circles, and the subsatellite path is indicated by the broken line.

but shelter temperatures of −80° C along with strong surface inversions have been recorded at Plateau Station located in the same general region.

Estimates of temperature and humidity profiles obtained from the spectrum taken over the Mediterranean

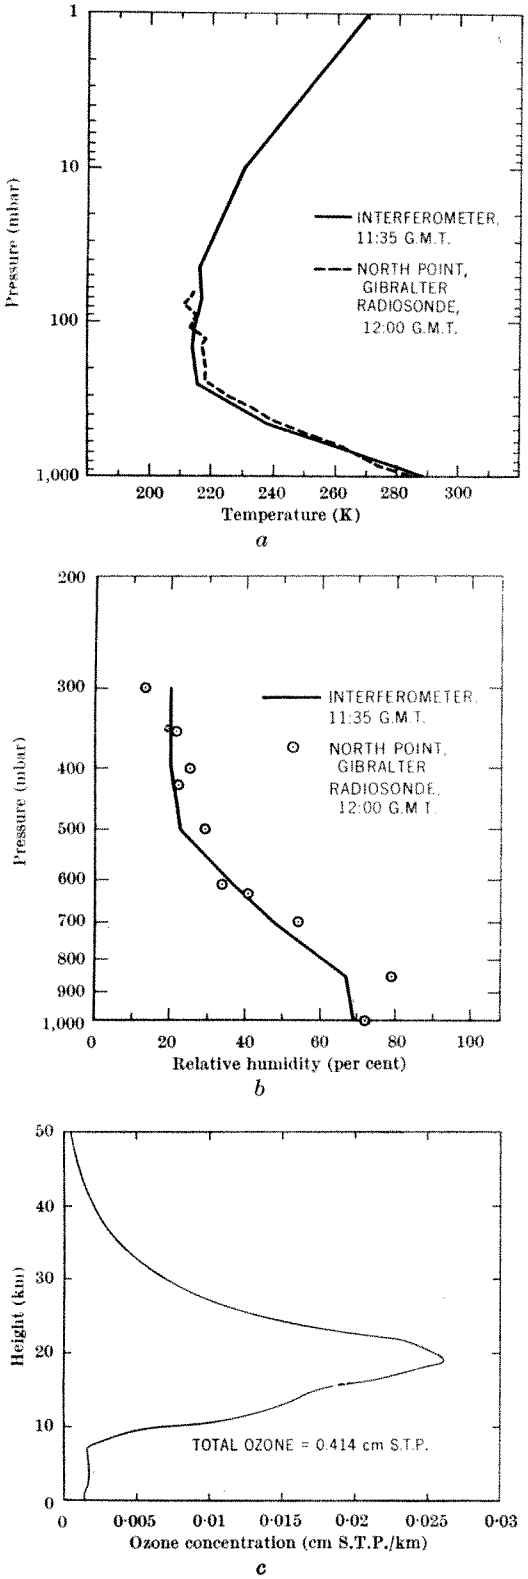

Fig. 4. Vertical profiles of atmospheric parameters obtained from the Mediterranean spectrum shown in Fig. 1. The profiles include (*a*) temperature, (*b*) relative humidity, and (*c*) ozone. Measurements of temperature and humidity obtained from a nearby radiosonde are shown for comparison.

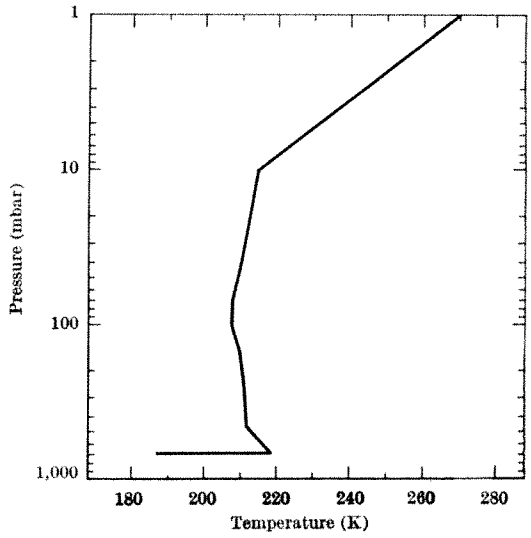

Fig. 5. Vertical atmospheric temperature profile obtained from the Antarctic spectrum shown in Fig. 1. A climatological value of 700 mbar was taken as the surface pressure. The actual thickness of the surface inversion layer could not be resolved with the temperature estimation technique, and the inversion appears as a discontinuity at the bottom of the profile.

are shown in Figs. 4*a* and *b*, respectively, where they are compared with data from a radiosonde launched from Gibraltar. The ozone profile inferred from the same spectrum is shown in Fig. 4c. The techniques used for obtaining the temperature and humidity profiles have been discussed by Conrath *et al.*[2] and the method for calculating ozone profiles by Prabhakara *et al.*[4]. Because of the interesting behaviour of the Antarctic spectrum, an estimate of the temperature profile for this case has been made (Fig. 5) even though no radiosonde data are available for comparison. The profile can be anticipated intuitively from an examination of the spectrum (Figs. 1 and 2). The warmer upper atmosphere is associated with the Q-branch of the CO_2 band at 667 cm^{-1} where the highest radiances in the band occur, while the approximately isothermal portion of the profile is associated with the more transparent portions of the CO_2 band and the stronger lines of the water vapour rotation band. The cold surface temperature results in the relatively low radiances found in the window region and between the water vapour lines.

These preliminary results show that the interferometer experiment on Nimbus 4 is providing high quality infrared spectra of the Earth and atmosphere. The low noise equivalent radiance, high spectral resolution, and broad spectral coverage make the data ideally suited for studies of atmospheric radiative transfer as well as the analysis and development of remote sensing techniques. The experiment also provides data for many geophysical and meteorological investigations. Temperature and humidity profiles derived from the spectra on a global basis will be useful in numerical modelling experiments of the atmospheric circulation.

We thank the many members of the Nimbus Project and the group at Texas Instruments Inc. who were responsible for the construction of the instrument. Dr C. Prabhakara provided the ozone profile estimate. We also thank Drs V. V. Salomonson, I. Revah, V. G. Kunde, and B. Schlachman for help and Mr G. Wolford for computer programming.

Precise Radio Source Positions: A Comparison of Two Independent Lists

MEASUREMENTS of radio source positions to an intended accuracy of 1 arc second or better have recently been carried out independently at the National Radio Astron- cm), although the actual methods which were use Both sets of observations were done by means of interferometry at a nominal frequency of 2,695 MHz (λ 11·1 cm), although the actual methods which were employed differ radically. The positions measured for the twenty-eight sources common to the two lists are generally in excellent agreement, as will be shown. Papers describing the methods used, and containing full lists of measured positions, will be published separately elsewhere (ref. 1 and unpublished work of Adgie *et al.*).

The measurements at the National Radio Astronomy Observatory were made with the three-element interferometer[2]. The position of each source was measured independently on at least two of the element spacings 16,200λ, 18,900λ, 21,600λ or 24,300λ. The technique was novel in that it yielded an absolute measurement of the source declinations, in no way dependent on previously determined coordinates for any radio source or on accurate previous knowledge of the geometry of the instrument. It also gave an absolute measurement of the right ascensions apart from an unknown zero-point which was fixed by requiring that the measured right ascensions agree in the mean with the optically determined values for the identified sources in the list (unpublished work of Kristian and Sandage). The NRAO programme dealt with forty-six sources, of which forty have known optical counterparts.

The measurements at the Royal Radar Establishment were made with the RRE two-element interferometer[3], with an element spacing of about 5,800λ along a north–south line. Each source was observed 4 h before and 4 h after upper culmination. Over a range of declinations from 0° to 60° this gives two sets of fringes which are close to position angles of ±45° and have almost the maximum resolution of 36 arc s. This arrangement has the great advantage that the measurement accuracy is almost independent of declination. No attempt was made to measure the baseline parameters directly, the system being calibrated with the optical positions of thirty-six identified sources[4–7]. The measurement of declination required the determination of three baseline constants and relied on having a good distribution of sources throughout the full declination range. For the right ascensions, only one constant was required; this fixed the zero point of the right ascensions, as in the NRAO measurements. But the optical right ascensions used by NRAO were taken from a new set of optical positions (Kristian and Sandage, unpublished) and were independent of the positions used by RRE. The RRE programme dealt with 178 sources.

There are twenty-eight sources common to the two lists, and their measured positions, with the differences between them and the estimated uncertainties, are given in Table 1. Fig. 1 is a cross-plot of the distribution of the position differences in the two coordinates. These position differences are closely grouped with the exception of the measurement for 3C 230. This source is undoubtedly confused somewhat by NRAO 340 (PKS 0950+00), so that its displacement from the group is not surprising.

The remaining twenty-seven position differences were allocated weights inversely proportional to the squares of their estimated uncertainties. Table 2 gives the resulting weighted mean position difference, together with the standard errors as calculated from the observed position residuals. The standard errors for one position difference are close to 0·5 arc s in each coordinate. This indicates

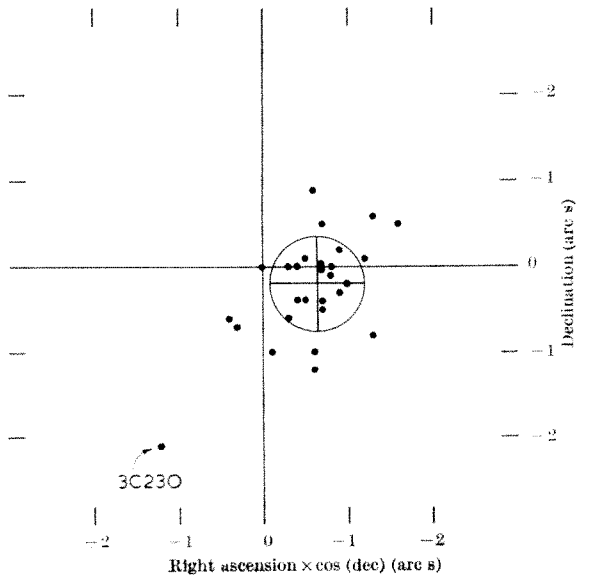

Fig. 1. Radio position differences NRAO–RRE. The circle (diameter 1·1 arc s) is the median circle of a two-dimensional Gaussian distribution having a standard error of 0·5 arcs in each coordinate.

that the random errors in each catalogue are about 0·35 arc s in each coordinate (about 0·025 s in RA).

The standard errors calculated from the estimated uncertainties given in Table 1 are about twice those given by the observed residuals. This is not surprising, for the uncertainties quoted for each catalogue are intended to include some allowance for systematic as well as for random errors.

Table 2. MEAN POSITION DIFFERENCES AND STANDARD ERRORS

	R.A.	R.A. cos (dec)	Dec
Weighted mean difference (NRAO–RRE)	−0·044 s ±0·006 s	−0·58″ ±0·09″	−0·19″ ±0·10″
Standard error of one position difference of average weight	0·034 s	0·46″	0·50″

The mean difference in declination is just less than twice its standard error, and can hardly be considered significantly different from zero. The close grouping of the two sets of measurements in declination is an important result, as it shows that measurements based on a sufficient number of optical calibrators (RRE) can give satisfactory agreement with absolute measurements (NRAO).

In the measurement of right ascensions the radio catalogues are on the same footing; they both give absolute R.A. differences but require optical calibrators to fix the R.A. zero point. The small standard error in the R.A. differences between catalogues indicates good agreement by NRAO and RRE in the measurement of relative right ascensions. The catalogues nevertheless differ significantly in zero point, by −0·044 s in R.A. The cause of this difference is not clear. The standard error of the mean R.A. difference is only 0·006 s, and this suggests that most of the discrepancy must arise from differences among the optical positions used to fix the zero point. Further consideration of such differences lies outside the scope of this letter, which is intended to draw attention to the existence of radio position lists having standard errors significantly better than 1 arc s.

H. G., R. L. A. and J. H. C. thank Professor Sir Bernard Lovell for support from the University of Manchester, Nuffield Radio Astronomy Laboratories, Jodrell Bank, without which the measurements at the Royal Radar Establishment would not have been completed. R. L. A. holds a Royal Society research fellowship supported by the Weir Foundation. Seasonal Changes in the Ionosphere

MARKED changes occur in the ionosphere during the year. In most studies statistical methods have been used because of the superimposed day to day fluctuation usually dividing the year into summer, winter and equinoctial periods. This type of examination, however, tends to mask the fundamental changes particularly at the equinoxes.

An important feature is that in the southern hemisphere the seasonal change is abrupt in the Sept–Oct equinox and more gradual in March–April. These changes appeared consistently during investigations in Australia of travelling ionospheric disturbances as a reversal of the N–S component of travel of TID's in late September or early October[1].

The effect showed up again in satellite observations. I demonstrated the simultaneous occurrence of ionization changes deduced from satellite records of total ionization and from ionosonde records, and changes in direction of TID's, in September 1958 (ref. 2). The occurrence of a magnetic storm at this time was noted and further observations indicated that a magnetic storm could trigger off the change. This has since been confirmed by Titheridge[3] in New Zealand from observations on a geostationary satellite, which showed that the seasonal change involved a major change in total ion content at all times of the day, and was initiated by a magnetic storm.

A comprehensive set of travelling disturbance data was available covering a period of twelve years, and a closer examination of that data was made.

The data consisted of records from a three-point system for observing the movements of travelling ionospheric disturbances near Sydney (lat. 34° S, long. 150° E). The period examined was from April 1948 to October 1959, covering a complete sunspot cycle. For the present investigation the deduced directions of horizontal movement of all disturbances were plotted for each day of the two month periods March–April and September–October in each year. These plots showed clearly that the seasonal change in direction was not a smooth transition but there were fluctuations between summer and winter directions lasting for a few weeks. This pattern was particularly obvious in the Sept–Oct period.

When the daily K_p indices were plotted it was found that the changes to the new direction were consistently associated with marked rises in K_p and temporary reversions after the main change were associated with low values of K_p.

In all years there were sufficient data to assess the significant changes. The features extracted for each

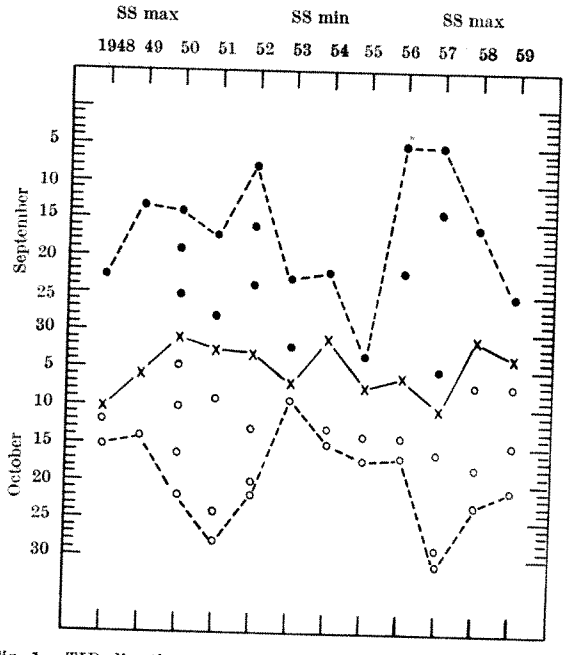

Fig. 1. TID direction changes, September–October. ●, Temporary change; ×, main change; ○, temporary reversions.

year were the temporary changes to the new direction, the main change after which the new direction predominates, subsequent reversions to the old direction and the final change to the new direction after the last temporary reversion, which is clearly defined in the September–October plots. These features are summarized in Fig. 1. Although there may be earlier temporary changes, the main changes all take place within the first ten days of October, the actual day apparently being decided by a magnetic increase. There are some subsequent temporary reversions but the final changes to summer directions all occur by the end of October. The variation in day of occurrence during the sunspot cycle is small but suggests a half-cycle variation and this seems more strongly indicated in the final change dates and on the time spread and number of temporary changes. The change on September 17, 1958 (ref. 2), was actually a preliminary one before the main change.

The transition shown by Titheridge in 1965 began on September 27 and the total change occupied about 25 days. The particular storm which initiated it could therefore correspond with a temporary change of direction of TID's. The total change period of 25 days seems to agree well with the average period when disturbance directions were susceptible to magnetic control (Fig. 1).

To confirm that the effect was essentially an equinoctial one a check of magnetic indices and disturbances was made for the other months of the years involved.

During the winter months, May to August, major changes of direction were rare. In the falling years of the sunspot cycle (1949–51) none were recorded. From 1952 to 1955 the rate of occurrence was about one per year associated with high K_p values. In 1956 there were three cases. 1957–58 were years of unprecedented sunspot activity and the summer influence extended into May and June, but in July and August winter directions were steady.

It seems clear, therefore, that the Sept–Oct equinox is a time of instability in the ionosphere and it is then particularly susceptible to fluctuations in the magnetic field which result in changes in the distribution of ionization and corresponding changes in the direction of travel of disturbances.

It seems that the magnetic fluctuations affect chiefly the north–south component of movement of disturbances and the directional changes are most marked in the Sept–Oct equinox when the north–south component predominates. At this time magnetic storms are known to have effects similar to the seasonal change and can thus have a triggering effect making the change seem quite abrupt.

In the March–April equinox the seasonal change in the direction of movement is more gradual, apparently for two reasons; magnetic disturbances tend to retard the seasonal change and the east–west component of movement is then predominant so that changes in the north–south component have less effect in terms of a direction change.

This letter aims only at presenting factual information and the results offer wide scope for theoretical interpretation. Duncan[4] provides a good basis by comparing the effects of seasonal changes and magnetic storms. The possibilities are obvious for extending the investigation in time, in height and in latitude using other types of data already available.

It is particularly desirable to have comparative information from the northern hemisphere. For current investigations geostationary satellite data would be most convenient, but for correlation with information for the earlier years described here ionosonde and earlier satellite records could be used.

Upper Bound to the Density Jump at the Boundary of the Earth's Inner Core

The Earth has an inner core about the size of the Moon. Convincing observations of the seismic waves PKiKP, reflected at steep angles from the inner core boundary (ICB), were announced by Engdahl *et al.* (annual meeting of the Seismological Society of America), using the Large Aperture Seismic Array (LASA) in Montana (epicentral distances $\Delta < 40°$). These identifications agree with expected travel times and wave slownesses[1] ($p = \mathrm{d}t/\mathrm{d}\Delta$), and pPKiKP minus PKiKP time lags.

This extraordinary discovery confirms the earlier identified[2] PKiKP waves, reflected at grazing angles from the ICB ($105° < \Delta < 110°$). It establishes once and for all that the ICB (radius $r \sim 1{,}216$ km) is sharp[3,4] relative to seismic longitudinal waves with periods of order 1 s. It also opens the way for the direct calculation, by purely seismological means, of the density contrast between the material of the outer (fluid) core and of the inner core.

Here we derive tentatively (partly to demonstrate the method involved) the first upper bound on this estimate, using measured amplitudes of PKiKP and PcP phases recorded at LASA. (The PcP phase is reflected at the sharp boundary between the mantle and outer core (MCB), at a radius of about 3,479 km.) The observed phases, shown in Fig. 1, were generated by the underground explosion Faultless (magnitude about 6·0) in Nevada ($\Delta \sim 10°{\cdot}9$). The directly measured amplitude ratio, $\mathcal{A}$ = amp PKiKP/amp PcP, should be a reliable estimator for two reasons. First, the phases (which have similar appearances) are recorded by the same seismometers and with identical processing; no instrumental or crustal adjustments are needed. Second, the downgoing PKiKP

and PcP rays leave the explosive source at almost the same angles of emergence ($e \approx 89°$, 87°, respectively). Consequently, no nodal surfaces of source radiation complicate the energy partition and we may assume that the wave amplitudes in the downgoing PKiKP and PcP rays are essentially equal.

The identified phases in Fig. 1 have residuals of only a few seconds against the appropriate standard travel time tables. Further, processing with the LASA array indicates slownesses of about 0·5 and 1·2 s deg^{-1} for the recorded PKiKP and PcP waves. These raw values are close to the expected values of $p = 0{\cdot}3$ and $p = 1{\cdot}0$ s deg^{-1}, respectively. Measurements of $\mathcal{A}$ from four independently processed groups of signals from different subclusters of the array yield a mean of $\mathcal{A} = 0{\cdot}38$ with a variation of about 5 per cent.

The raw value for $\mathcal{A}$ must, however, be adjusted for the relative geometrical spreading τ_{ig}, of the two waves, as well as the relative frictional attenuation τ_{iQ}. Given the P velocity distribution down to the ICB, the value of τ_{ig} can, in principle, be determined exactly. By theory, for the same source and receiver, apart from a factor 1/4 involving the angles of incidence

$$\tau_{ig}^2 = \left| \left(\frac{dp}{d\Delta}\right)_{PKiKP} \Big/ \left(\frac{dp}{d\Delta}\right)_{PcP} \right| \qquad (1)$$

For steep reflexions, the seismic rays are approximately straight lines. In this case, we easily derive

$$\frac{dp}{d\Delta} = \frac{1}{2} p \cot \frac{\Delta}{2} - \frac{1}{t} p^2 \qquad (2)$$

where Δ is the epicentral distance and t is the travel time of the phase in question. From equation (2), $\tau_{ig} = 0{\cdot}47$ for $\Delta = 10°{\cdot}9$. In principle, τ_{ig} can be checked,using equation (1), from the curvature of the empirical travel time curves; in practice, uncertainties in measuring curvature are high. Present standard tables suggest $\tau_{ig} \approx 0{\cdot}5$–$0{\cdot}6$.

The PKiKP waves reflected from the inner core have additional frictional attenuation compared with the PcP waves. The former travel a further distance of more than 3,500 km through the liquid outer core. (Special effects due to the outer boundary and physical state of the 440 km thick transition shell[4] around the inner core are ignored throughout this argument.) Suppose the attenuation of the wave amplitude varies like

$$\tau_{iQ} = \exp(-\pi t / Q\tau) \qquad (3)$$

where τ is the period, and Q a dimensionless attenuation factor.

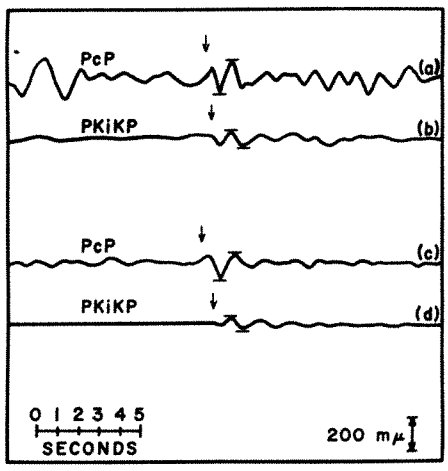

Fig. 1. Seismograms at LASA, Montana ($\Delta = 10°{\cdot}9$) from the underground nuclear explosion Faultless in Nevada on January 19, 1968. The traces are: *a* and *b*, signal sum of 25 seismometers in the C_4 cluster; *c* and *d*, velocity-filtered sum from seismometers across complete array. Arrows show phase onsets, horizontal bars show amplitudes measured.

In the liquid outer core, the value Q_c for P waves of period 1 s is probably in excess of 10,000. Seismic measurements indicate that Q values for P waves increase to about 1,500 near the base of the solid mantle. The purely radial free oscillation of the Earth, ${}_0S_0$, persists for weeks after great earthquakes, favouring a mean Q value greater than 10,000 for compressional vibrations of the whole Earth. More direct values for Q_c can be obtained from amplitude measurements of the family of seismic waves PKP, PKKP, PKKKP, and so on, although this work has not yet been done. These waves are multiply reflected from the underside of the MCB; PKKP has two legs in the outer core, and so on. Such waves with three and four legs are often recorded under appropriate observational conditions. Engdahl[5] has reported observing multiple reflexions up to PKKKKKP. Rough calculation suggests that these observations require $Q_c > 10{,}000$. From equation (3), this value gives $\tau_{iQ} \geq 0{\cdot}85$.

The required density ratio d_I at the ICB arises as follows. Let subscripts 0, 1, 2, 3, 4 refer to the terrestrial surface, the top and bottom of the MCB and ICB, respectively. Let e and f be the angles at which P and S waves emerge at a boundary.

Consider the ray system generated by an incident P wave at the ICB in terms of the P and S potential functions[6] φ and ψ; incident and reflected waves in the liquid core may be represented by

$$\begin{cases} \varphi_3 = A_3 \exp\{i\varkappa(z \tan e_3 + x - ct)\} \\ \qquad\qquad + C_3 \exp\{i\varkappa(-z \tan e_3 + x - ct)\} \\ \psi_3 = 0 \end{cases} \qquad (4)$$

where $2\pi/\varkappa$ is the wavelength, and z is along the radius towards the centre. Similarly, the potentials for refracted P and SV waves in the inner core (assumed solid) are

$$\begin{cases} \varphi_4 = D_4 \exp\{i\varkappa(z \tan e_4 + x - ct)\} \\ \psi_4 = B_4 \exp\{i\varkappa(z \tan f_4 + x - ct)\} \end{cases} \qquad (5)$$

Three boundary conditions apply: zero tangential stress (to a close approximation) and continuity of normal displacement and normal stress. The resulting three equations in the unknown amplitudes A_3, C_3, D_4, B_4, are

$$\begin{bmatrix} \tan^2 f_4 - 1 & 0 & 2 \tan e_4 \\ 1 & -\tan e_3 & -\tan e_4 \\ 2\beta_4^2 \tan f_4 & d_I \alpha_3^2 \sec^2 e_3 & -\beta_4^2(\tan^2 f_4 - 1) \end{bmatrix} \begin{bmatrix} B_4/A_3 \\ C_3/A_3 \\ D_4/A_3 \end{bmatrix} = \begin{bmatrix} 0 \\ -\tan e_3 \\ -d_I \alpha_3^2 \sec^2 e_3 \end{bmatrix} \qquad (6)$$

The third equation contains the required $d_I (= \rho_3/\rho_4)$ at the ICB. Equation (6) together with appropriate triads from MCB continuity conditions may be solved simultaneously for $\mathcal{A}$ as a function of adopted values for d_I and β_4, the (unknown) shear velocity in the inner core.

From recent seismological studies[7–10] the values adopted as most likely, in usual units, for density ρ, P velocity α, S velocity β at MCB and ICB are: $\rho_1 = 5{\cdot}51$, $\alpha_1 = 13{\cdot}20$, $\beta_1 = 6{\cdot}99$; $\rho_2 = 9{\cdot}70$, $\alpha_2 = 7{\cdot}99$; $\rho_3 = 12{\cdot}35$, $\alpha_3 = 10{\cdot}31$, $\alpha_4 = 11{\cdot}23$. The reflexion coefficient for steep PcP rays at the MCB is roughly proportional to a term $|\rho_2\alpha_2 - \rho_1\alpha_1|$ which is quite sensitive to the uncertainties of the particular combination of densities and velocities which have been estimated for the MCB. The adopted values give a high (but not maximum) value to this term. The choice is

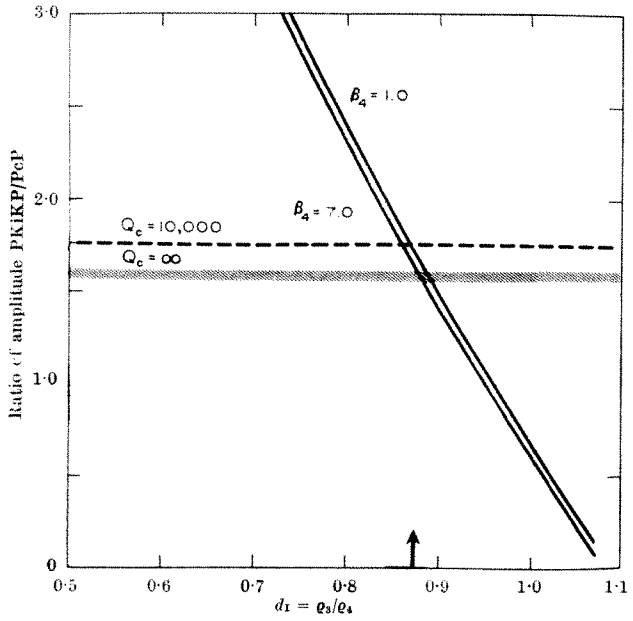

Fig. 2. The variation of the amplitude ratio PKiKP/PcP at the Earth's surface for $\Delta = 10°{\cdot}9$ as a function of d_I, the density ratio at the inner core boundary.

consistent with seeking a lower bound to d_I at ICB (and hence a high reflexion coefficient for PKiKP there).

The results of the computation are shown in Fig. 2 for two representative cases, $\beta_4 = 1{\cdot}0$ and $7{\cdot}0$. The small offset between the two curves is a result of the small proportion of wave energy converted to SV waves in the inner core at steep angles of incidence. Ignorance of the actual β_4 values does not, therefore, much affect the uncertainty in the lower bound to d_I. (Derr[9] inferred $\beta_4 \approx 2{\cdot}2$ km s^{-1} from observations of terrestrial free oscillations.)

The broad horizontal line in Fig. 2 represents the observed value of the amplitude $\mathcal{A}$ adjusted for the complete geometrical factor 0·24 only ($Q_c = \infty$). The parallel broken line corresponds to $\mathcal{A}$ after allowance for the frictional attenuation $Q_c \approx 10{,}000$.

From the region of intersection of the curves we deduce that a fairly extreme minimum value of d_I is 0·86; a more likely minimum is perhaps 0·875. For the plausible value[9–11] of $\rho_3 = 12{\cdot}35$, these ratios suggest a maximum density jump at the ICB of less than 1·8 g cm^{-3}. The relatively steep slope to the curves in Fig. 2 strengthens the overall argument by demoting the various uncertainties associated with the adjusted observed estimate of $\mathcal{A}$.

It is quite remarkable that seismological evidence alone can establish that, 1,200 km from the Earth's centre, the density does not exceed 14·25 g cm^{-3}. (The pressure at this radius is $3{\cdot}3 \times 10^{12}$ dyne cm^{-2}.) Only a few years ago, central densities in the Earth as high as 18 g cm^{-3} were seriously considered. Uncertainties in the present bound need to be checked from many additional observations of recorded PcP and PKiKP amplitudes. (The ratio of the amplitudes of PKPPKP and PKiKP, also recorded on the same seismogram, should provide an additional equation of condition.)

The result $\rho_4 < 14{\cdot}25$ is in close agreement with recent core models of Bullen[10], and also with Birch's conclusions[12], based partly on the results of shock wave experiments on iron, that the Earth's central density is close to 13 g cm^{-3}. The principles involved in making the present estimate do not depend, of course, on assumptions concerning the chemical composition of the core. If the bound reported here can be confirmed, important inferences on the composition of the whole core follow.

This research was supported by an NSF grant. We thank Dr J. Filson at Lincoln Laboratory, MIT, for his help in obtaining the LASA seismograms, and Dr L. Johnson and De G. R. Buchbinder for criticisms. A more refined analysis will be presented elsewhere.

Eustatic Sea Level Changes in the Arafura Sea

The lowest eustatic sea level during the past 35,000 years has until recently been estimated to be -130 m[1]. Preliminary results of recent marine geological research in the Arafura Sea substantiate the evidence[2] for a worldwide eustatic lowering of sea level of more than 130 m between 21,000 and 14,000 yr BP. Observations in the Arafura sea also support contemporary discoveries[3,4], which resulted from the introduction of submersibles and narrow beam echosounders, of submarine terraces down to 200 m. These deep terraces reflect a much lower sea level earlier in the Pleistocene. Radiometric dating of a shallow-water reef coral, recovered from a terrace at -200 m during descent in the Japanese research submersible Yomiuri, gave an age greater than or equal to 170,000 yr BP.

The morphology of the Arafura is that of a submerged subaerially eroded landsurface[5], with a fluvial pattern of channels and drowned reefs near the edge of the shelf[6]. Near the Australian coast the old subaerial[2] topography has been covered by fine grained marine sediments. Depths on the shelf are generally between 50 and 80 m and the edge of the shelf is usually between 120 and 200 m. The southern part of the shelf has undergone very little movement since the late Pliocene[7]. During 1969, the Bureau of Mineral Resources carried out a marine geological survey of the Arafura shelf and covered most of the area by dredge sampling, gravity coring, shallow continuous seismic profiling and echosounder profiling. In addition, three traverses across submarine terraces were undertaken (Fig. 1) in the Japanese submersible Yomiuri.

A number of terraces and nickpoints representing low sea level stands have been observed in echosounder and continuous seismic profiles at depths of 64 m, 90 m, 130 m, 170–175 m and at about 200 m. The first three of these terraces correspond closely to those reported on other parts of the continental shelf of Australia such as the Sahul Shelf[7] and the Great Barrier Reef[8]. A shallow-water fossiliferous algal rock recovered by dredge from a submerged reef between 130 m and 175 m (station 1231, Fig. 1) gave a radiocarbon date of $18{,}700 \pm 350$ yr BP (Table 1). This rock is older than the shell material obtained from a 130 m surface on the Sahul Shelf[7] ($16{,}910 \pm 500$ yr BP), and it is possible that the rock came from a depth significantly greater than 130 m. The terrace between 170 and 175 has not yet been dated. A platy

fossiliferous beachrock, which was collected during dive III at a depth of 150 m (Fig. 1), may correspond to a terrace at similar depth off the Great Barrier Reef[2], apparently formed 13,600 to 17,000 yr BP.

The still deeper terrace at −200 m observed in the seismic and echosounder profiles was investigated by submersible (dive II, Fig. 1). A traverse across the feature revealed a mud-filled channel with a maximum depth of 210 m at the base of a scarp 20 m high. Samples of rock from the base of this scarp at 200 m depth were collected with the mechanical arm of the submersible. The rocks consisted of a mixture of shallow-water reef coral, abraded mollusc and foraminiferal fragments, bryozoans, and algal fragments, cemented loosely by calcite. A high proportion of void space and the presence of material affected by wave action suggest a littoral origin. Radiocarbon dating gave an age greater than 30,000 yr BP for this material (Table 1). Further dating by H. H. Veeh of the Australian National University using the uranium series method on unrecrystallized coral in one of the samples indicated an age of 170,000 yr or more. This shows that the 200 m terrace was formed before the last glacial lowering of sea level, possibly during one of the previous glacials. A similar suggestion has been made by Dill[3] for the deep sea terraces discovered on the continental slope off California and around most of Australia. Thus there is reason to accept a lowering of sea level greater than the 130 m earlier postulated[1], during the late Würm Glacial to about −175 m[2], but the deeper terraces in the Arafura Sea and those discovered by Dill[3] between depths of 182 m and 214 m are older than this, and may have been formed by sea level lowering during one of the previous glacials. As earlier demonstrated by Donn *et al.*[9] the maximum eustatic lowering of sea level took place during the Riss glacial; this glacial could be the period during which the deeper terraces originated.

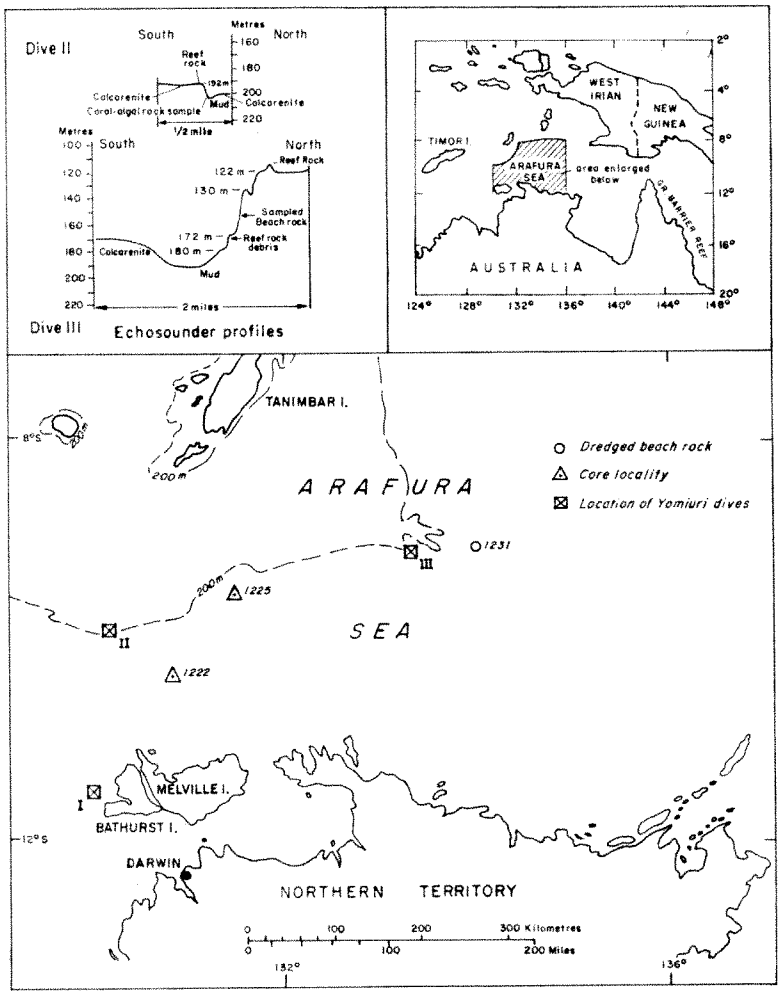

Fig. 1. Locality map of dated samples and submersible descents with echosounding profiles in the vicinity of dives II and III.

Two further dates of material from short cores are available. Core No. 1225 (Fig. 1), water depth 117 m, was stopped by a shelly horizon 125 cm below the surface. Abraded shells from the bottom of this core gave an age of older than 30,000 yr BP by the radiocarbon method (Table 1). Core No. 1222, water depth 99 m, struck wood 130 cm below the surface, which gave a radiocarbon date of 14,500 ± 700 yr BP (Table 1). These two dates point to marine transgressions at around 14,000 yr BP and before 30,000 yr BP; the earlier event is subject to serious doubt because the worn shell material may not be a littoral deposit and, even if it is, the shells may significantly antedate the transgression. The wood appeared to occur in a fossil soil, but here again the possibility that it is derived must be borne in mind.

The history of sea level changes in the Arafura Sea agrees with that of other areas in Australia[2,8], the east coast of America and the south-east Caribbean Sea[10]. Dates from recently collected material in the Arafura Sea indicate a eustatic lowering of sea level to about −200 m before 170,000 yr BP. This was followed by a transgression before 30,000 yr BP, and a subsequent lowering of sea level to −175 m after 20,000 yr BP. A rise in sea level to its present position eventuated soon after 14,500 yr BP.

Table 1. RADIOMETRIC DATES OF ARAFURA SEA SAMPLES

Station No.	Location	Depth (m)	Age BP (years)	Material
1,231	9 07′ S 133 52′ E	130–175	18,700 ± 350	Beach rock
Dive II	9 55′ S 130 03′ E	210–200	⩾ 170,000	Coral*
1,225	9 44′ S 131 0′ E	117	> 30,000	Shells, base of 125 cm core
1,222	10 20′ S 130 46′ E	99	14,500 ± 700	Wood, base of 130 cm core

Radiocarbon dates were supplied by the Department of Nuclear and Radiation Chemistry, University of New South Wales, NSW, Australia.

* Dating by H. H. Veeh of the Australian National University.

The uranium/thorium date was supplied by Dr H. H. Veeh of the Australian National University. Dr H. A. Jones and Mr D. S. Trail of the Bureau of Mineral Resources collaborated in the collection of field data and in discussion of the results. The collection of some of the samples was made possible through the assistance of the Yomiuri Newspaper Company, who put the submersible at our disposal.

Plane Bed Thresholds of Fine Grained Sediments

WHEN the flow of fluid over a plane bed of loose grains is increased from zero, a condition is reached where a few grains move. This is known as the threshold of grain movement. This report describes the determination of the threshold under flows of water and oil for beds of mineral grains of uniform size with diameters between 20 and 200 μm.

Shields[1] proposed that the tangential fluid stress at the boundary τ_0 responsible for grain movement at the threshold should be combined with the weight, per unit area of the bed, of the particles forming its topmost layer. This gives a non-dimensional entrainment function

$$\theta_0 = \frac{\tau_0}{(\sigma - \rho)gD}$$

also known as the dimensionless fluid stress[2], σ and ρ being the densities of grain and fluid, g the gravitational acceleration and D the particle diameter. The boundary Reynolds number is defined as U_*D/ν where $U_* = (\tau_0/\rho)^{\frac{1}{2}}$ and ν is the kinematic viscosity of the fluid. If the threshold values of U_* and θ were labelled U_t and θ_t, Shields argued on dimensional grounds that θ_t should be a function of U_tD/ν only.

This has been confirmed several times[3-6]. It has been established that θ_t is nearly constant, at about 0·05, for a wide range of diameters greater than 200 μm.

200 μm is a critical diameter for plane beds of geologically important minerals. Above this diameter such beds are hydrodynamically rough at the threshold, below it they are smooth[7,8]. There is every reason to suspect that the value of θ_t for finer grains will be greater than the value of 0·05 found for coarser material because when the bed is hydrodynamically smooth a laminar sublayer is established in the fluid immediately above it. Short-lived velocity fluctuations that can perhaps quadruple the instantaneous force on exposed particles for a given mean stress[9-11] are much reduced. Bagnold has argued[2] that θ_t should not, however, exceed 0·4 for cohesionless grains.

Little has been published about the thresholds of plane beds of material under 200 μm diameter. Hjulström's[12] work on river sediments is often quoted as showing that the absolute value of stress necessary for erosion increases as the size decreases below this value. It appears that θ_t increases to a value greater than 10 for $D = 10$ μm. Rees[6] reports a value $0{\cdot}1 < \theta_t < 0{\cdot}4$ for a clean 10 μm silt.

New threshold determinations have been made in a recirculating flume 6 m long and 30 cm wide (Fig. 1), equipped with an orifice plate flow gauge[13] for discharge measurement and a micrometer point gauge for measuring water heights and hence surface slopes. Depth of flow and bed surface slope were measured with the microscope used for threshold observations. Thresholds were determined by observing through a microscope the first movement of a plane sediment bed as the fluid stress over it was increased.

Observations were made using closely sized fractions of quartz sands and silts, obtained by sieving and by air and water elutriation of natural materials. Particular care was taken to remove very fine grained material. The sphericity and angle of repose of each sediment grade were estimated microscopically. Other measurements were made using spherical lead glass "ballotini", crushed silica and crushed plastic of about 2 mm diameter.

Two fluids were used, tap water and Mentor 28 oil ($\nu = 0{\cdot}08$ Stokes). All water flows were turbulent, but most of those with oil seemed laminar. Values of bottom stress in good agreement were estimated using du Boys's equation $\tau_0 = \rho g h \beta$ where h is the depth of flow and β its surface slope, and by using established engineering formulae. Corrections were made for accelerations and for side wall effects.

Sediment beds in water were prepared for threshold determination by depositing the material grain by grain from water moving not quite strongly enough to cause erosion. In the oil experiments, beds had to be prepared by raking.

The threshold stress of each bed was measured about ten times with different depths of water. The range of depths was limited by the apparatus to 2–7 cm. Table 1 gives the mean values of θ_t. Fig. 2 shows the results plotted, together with those of other workers, on a diagram of θ_t against U_*D/ν. The broken line is an extrapolation made by Shields.

The results add further confirmation to Shields's general argument although they do not agree with his extrapolation. Within the experimental scatter a single curve relates measurements made with a thousand-fold range in the boundary Reynolds number by means of a hundred-fold range of submerged density and an eight-fold range of fluid viscosity. θ_t increases for low values of the Reynolds number, U_*D/ν to a value approaching the theoretical maximum of 0·4 suggested by Bagnold.

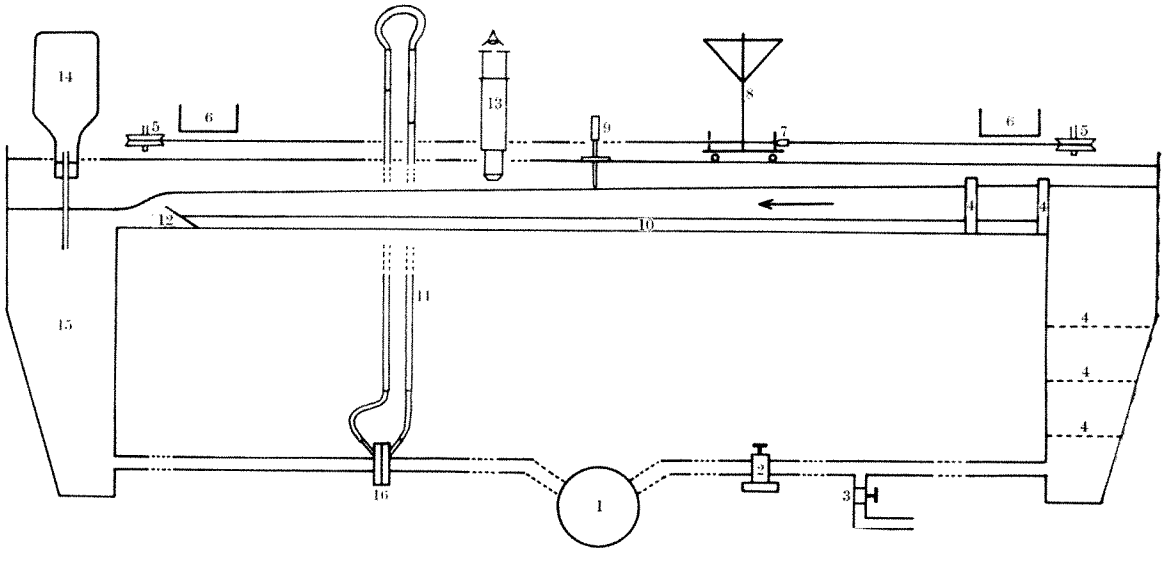

Fig. 1. The flume and apparatus. 1, Centrifugal pump; 2, flow-rate valve; 3, outflow top; 4, baffle plates; 5, pulleys; 6, collecting boxes; 7, messenger; 8, sand hopper; 9, micrometer screw gauge; 10, sediment bed; 11, differential manometer; 12, weir; 13, travelling microscope; 14, silt hopper; 15, fluid; 16, flow gauge.

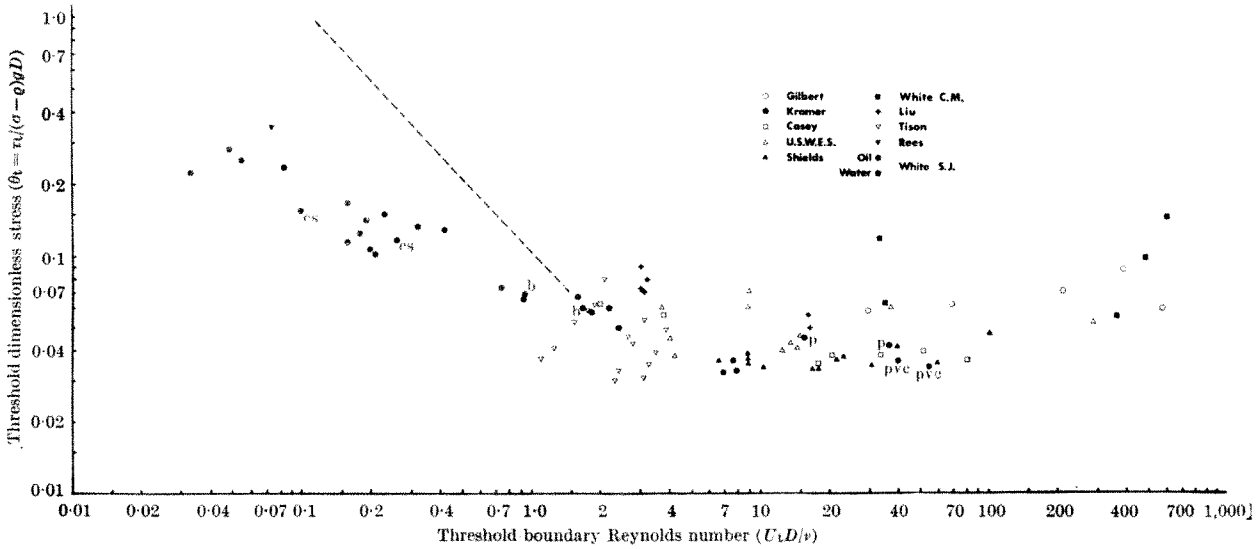

Fig. 2. The threshold of sediment movement as a function of the boundary Reynolds number. b, Ballotini; cs, crushed silica; p, polystyrene; pvc, Welvic P.V.C.

It was thought that it might be possible to detect a correlation between θ_t and the physical properties of the sediments used. Multiple regression analyses showed no correlation between θ_t and such sediment properties as sphericity, sorting and angle of repose. Neither was any relationship found between θ_t and the depth of flow or the surface slope of the fluid.

Table 1. MEAN VALUES FROM THE EXPERIMENTS

Evidence was sought for "ageing" of the bed during each series of experiments. The bed laid down initially by deposition or by raking might be more or less resistant to erosion than a bed the surface of which had been modified by exposure to stresses at or near to the threshold. No correlation was found between measured threshold and the order of the experiments, however, and it was concluded that no significant ageing took place.

This investigation is not complete because it deals only with plane bed thresholds of sediments that are as near as possible free of the cohesive material that is a frequent component of their size equivalents in nature.

I thank the Esso Petroleum Company Ltd for the gift of Mentor 28 oil, British Industrial Sands Ltd for the fine sand and Professor D. H. Griffiths for many of the silts. This research was supported by a studentship and a research grant to Professor H. Charnock from the Natural Environment Research Council.

Silurian Fossils from New Zealand

IN spite of its relatively small land area, New Zealand contains a remarkably complete fossil record. Up to the present the Carboniferous and the Silurian have been the only two Phanerozoic geological periods not known to be represented by fossils. The apparent absence of Silurian fossils has been considered strange because upper Ordovician and lower Devonian fossils are present in sedimentary sequences in north-west Nelson, South Island, which do not seem to be interrupted by regional unconformity, and which therefore presumably contained sediments of Silurian age[1]. The conclusive identification of Silurian fossils from north-west Nelson is therefore of considerable interest.

A useful summary of the history of geological endeavours in New Zealand is provided by Waterhouse[2]. In particular he pointed out that a Silurian age had, in the past, been wrongly assigned to several of the principal shelly faunas and rock groups of the South Island. For instance, the Haupiri Group of north-west Nelson was considered Silurian on stratigraphic grounds until Benson recorded[3] Cambrian trilobites. Similarly the Baton River fauna[4] of north-west Nelson was considered Silurian[5] until Shirley

showed[6] the fauna to be Lower Devonian (see also ref. 7). Grindley *et al.* considered[8] the Silurian to be represented in Nelson by unfossiliferous argillites (Wangapeka Formation of ref. 1).

Credit for discovering the first Silurian fossils goes to Professor Harold Wellman who collected in 1960 a boulder containing fragmental brachiopods from Dry Stream at the southern end of Takaka Valley, north-west Nelson. Should the Wangapeka Valley *Notoconchidium* fauna (see later) prove to be Silurian, this credit would go to Dr L. R. Grange for collections made in 1923–24. Subsequently Cooper[9], following up Wellman's reconnaissance, collected a number of deformed fragmental brachiopod moulds from quartzites and sandstones of the Hailes Knob Quartzite near Hailes Knob, in the same district. The collections on which this report is based were made by the authors with M. R. Johnston and D. N. Williams during February 24–26, 1969, and are chiefly from new localities in the same formation.

The Hailes Knob Quartzite (about 196 m thick) is composed principally of metaquartzite and quartz sandstone and outcrops as a small (about 5 square km) synclinal inlier along the crest of the Pikikiruna Range. The Hailes Knob Quartzite is underlain conformably by Mount Arthur Marble from which upper Ordovician conodonts are known[10]; overlying beds are not preserved. Identifiable fossils are confined to the uppermost beds. Collections are dominated by brachiopods and are principally from leached gritty sandstones. Although restricted in variety, the brachiopod faunas include material best referred to the Silurian pentameroid, *Conchidium*[11], as well as dalmanelloids and strophomenoids; indeterminate tetracoral, trilobite and crinoid remains also occur. The age of the fauna is late Wenlockian or Ludlovian. Thus the Ordovician–Silurian boundary probably lies near the top of the Mount Arthur Marble at Hailes Knob. It should be noted that further south, beds above similar limestones are Upper Ordovician[12].

A second fauna, from quartz sandstones of the Wangapeka Valley, 40 km to the south, has been re-examined and found to contain the brachiopod *Notoconchidium*[13,14]. Other fossils include *Pleurodictyum* (now definitely known from the Silurian of Australia[15–17]) and *Molongia*; the single poorly preserved brachiopod specimen referred[13] to *Schizophoria* is now thought to be more probably a strophedontid. It has recently been suggested[13] that *Notoconchidium*, previously thought to be Lower Devonian in age in Victoria, Australia[15], is confined to the Ludlovian, suggesting a Silurian age for the Wangapeka Valley fauna. But Devonian age has recently been demonstrated[19] for upper beds of the Yass (NSW, Australia) sequence (see also ref. 20); from this a probably Gedinnian age can be inferred for *Notoconchidium*-bearing strata at Heathcote (Victoria, Australia). Thus the age of the *Notoconchidium* beds in New Zealand is uncertain.

Grindley mapped[1] the fossiliferous quartz sandstones of the Wangapeka Valley as Ellis Formation, but he was unaware of the Hailes Knob Quartzite; strata mapped as Ellis Formation elsewhere have so far proved unfossiliferous. Near Baton River, the Baton Formation lies unconformably on older rocks[4], apparently excluding the Ellis Formation. Detailed mapping, collecting and faunal studies between Takaka Valley and Wangapeka Valley are required to elucidate the relationships of Ordovician to Devonian sediments in that region of north-west Nelson. Accurate determination of the age of the New Zealand *Notoconchidium* fauna may have important implications for some East Australian Siluro–Devonian sequences.

We thank the New Zealand Department of Scientific and Industrial Research for helicopter transport kindly arranged by G. W. Grindley and T. M. Hunt; M. R. Johnston and D. N. Williams (all NZDSIR) for field assistance; and Professor A. J. Boucot (Oregon State University) for advice on the Hailes Knob brachiopods. A. J. W. was supported by funds from the NZ Universities Grants Committee and the Victoria University of Wellington.

Disposal of Waste Material in Tectonic Sinks

GEOPHYSICAL phenomena such as deep earthquakes seem to mark zones where the material of the Earth's surface is being drawn into the mantle. The processes concerned take place at geological rates, and it may be estimated that surface material takes a million years to reach a depth of 25 km. Nevertheless, the process is often locally concentrated, so that subsidence is accompanied by grossly intensified accumulation of sediment where it should be possible to dispose of unwanted material permanently and in unlimited quantity.

Global production of industrial and domestic waste continually increases. A single nation produces more than 1 million tons per day of solid waste[1] and further regions are becoming industrialized so that worldwide production will increase without limit. The principal difficulty lies not in the sequestration of highly toxic material but in disposing of industrial and domestic refuse with low toxicity but large volume.

The solutions so far proposed have been but palliative[2]. Organic waste may be treated for use as fertilizer so that re-cycling is almost complete, but as technology progresses, solid waste containing metals and plastic is becoming more diversified and its elements more tightly bound, putting further beyond reach its sorting and re-use. Incineration does no more than re-distribute waste matter in the form of solid residue and atmospheric pollution. Energy considerations make it difficult to consider seriously proposals to inject unwanted material into orbit, or to dispose of it by nuclear burning.

At present the most widespread practice is to discard waste locally in makeshift fashion, under such appellations as "land fill". This solution is reaching its limits

Fig. 1. Location of sea-floor trenches and gravity anomalies associated with zones of subduction in the crust and mantle. The locus of surface-consumption on the floor of the trenches, shown in detail in Fig. 2, is too restricted to be visible at this scale. The fleches are plotted on the plate which is underthrusting, or being overthrust by, its neighbour.

simply because of a shortage of space. In some regions—San Francisco, for instance—the situation is such that train services have been organized to deposit refuse hundreds of kilometres from its source.

The practice entitled "ocean dumping", in effect the disposal of waste matter by sinking it at sea, offers no more prospect of being a solution than would be random "continental dumping". Yet restricted localities on the sea-floor are the site of downwarping and rapid sedimentary burial connected with events taking place in the Earth's interior. The processes responsible have not yet been elucidated, but the most plausible explanation is that an outer layer of the mantle is subject to circulatory convection.

Material is being added to the floor of the world ocean from below, in such a fashion that a process of spreading takes place outward from the axis of the ocean ridges[3,4]. Spreading takes place at a rate of between 3 and 9 cm per year, varying with locality. On a conservative assumption that the average spread rate is 5 cm/yr, that the ridge system is 40,000 km in length, and that a crust only 30 km thick takes part in this process, 60 km^3 of new crust is being added to the Earth's surface each year. As the planetary volume is changing less than this amount if at all, a corresponding volume of "old" crust must somewhere be replaced in the planetary interior. The sea-floor magnetic pattern indicates that the replacement process is not being effected by a general thickening of the crust, but is concentrated in zones of subduction (Fig. 1). These are marked by deep-seated seismicity, negative gravity anomalies, and tectonic trenches or foredeeps. In these localities crustal material is being drawn into the mantle.

On the basis of the magnetic evidence, more than 2,000 km^2 is being added to the Earth's surface each millennium and an equivalent area destroyed. It is not conceivable that surface destruction can take place without engulfment of material which has been deposited on the surface. Engulfment also takes place in concentrated fashion, in this case in the foredeep or trench fronting the zones of subduction.

A view common within the geological fraternity is that the tectonic trenches form where plate-like segments of the crust impinge on one another, resulting in thrusting of one plate beneath its neighbour. The subsurface form of some trenches, indicative of their deformation mode, is shown in Fig. 2. This is based on acoustic investigations with the restriction that detail is revealed only in the uppermost layers. In consequence it has not been possible to determine whether subduction takes place principally by subsidence and enfolding of the sea-floor, by its being thrust beneath the continental margin, or by a combination of both processes.

The convective process is slow, so that on the average an element of the Earth's surface must be exposed for a period in years equal to the surface area of the Earth divided by the area annually destroyed—$2{\cdot}6 \times 10^8$ years on the basis of earlier reckoning. In reality, however, depositional re-cycling and growth of the cratons result in gross departures from the average.

At points within sedimentary sinks the burial process is at its most rapid, because there the sediment from part of a continent may be deposited within a small area. Within a zone of 12 km^2 at the debouchment of the Fraser, for example, a river of intermediate size draining part of British Columbia, sediment deposited annually is in excess of 30 cm in thickness, ranging up to 6 m/yr in the foreset beds off the mouth of the river[8,9]. Conversely, almost no sediment has been found on the floor of the trench flanking western South America where the climate is arid[10].

The burial of surface material is therefore concentrated locally for two reasons: (1) the surface trace of subduction zones forms less than 1 per cent of the Earth's surface; (2) burial rate is multiplied a million or more times near the mouth of a major river. In places these factors operate together. The result is that in sedimentary sinks located within zones of subduction deposited material is buried within a few months and will never be seen again.

Depositional sinks of this nature are unique, for only here may material be said to disappear, ultimately into the planetary interior, without effort on our part. The

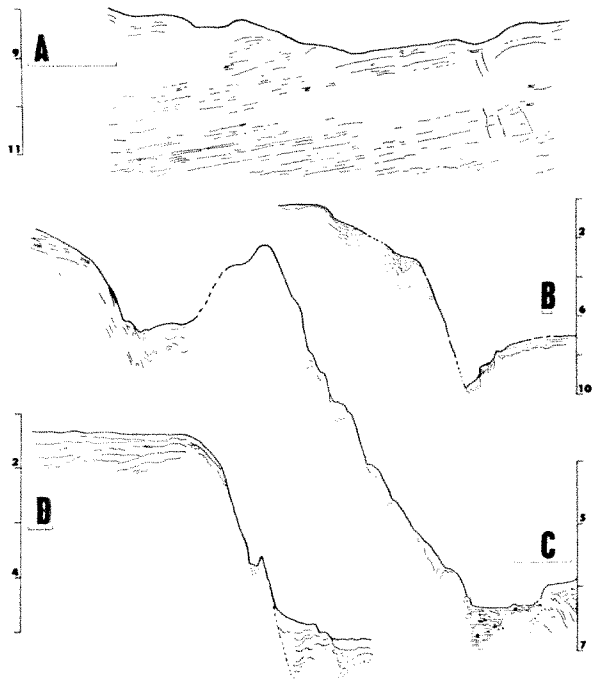

Fig. 2. Sediment accumulation and deformation in representative tectonic trenches, shown by acoustic profiling. Locations are shown in Fig. 1. In each profile the scale bar below the letter represents a horizontal distance of 10 km. The digits describe the two-way travel time in seconds. The topography of the trench is determined by the rate of sedimentation in relation to the rate of subsidence. In *A* (south-east extremity of Puerto Rico Trench; line drawing from profile published by Chase and Bunce[5], so far as possible omitting off-line events and multiples), the floor of the Atlantic on the right is underthrusting or being overthrust by the Caribbean crustal section, left; sediments are available only from nearby islands. A common feature in the tectonic trenches is the presence of one or more benches playing the part of sediment traps, as in *B* (Japan Trench, after Lugwig *et al.*[6]). Slumping and turbidity currents play a large part in sedimentation filling these and the trench floor (*C*, Middle Americas Trench, after Ross and Shor[7]), leaving the steeper slopes thinly covered with sediment in an unstable condition. In areas of heavier sedimentation or slower subsidence (*D*, Middle Americas Trench[7]), the topographic outline of the trench is obscured by infill.

refuse production of the globe, for example, would be buried as fast as it is produced if it were deposited in compacted form at the foot of the foreset beds of such rivers as the Fraser. The delta of the Fraser is located within narrow waters and is not suited for the disposal of waste, nor is its locality known with certainty to represent a zone of subduction. Deposition by this river, however, must be exceeded by that in many less completely surveyed.

We should perhaps regard such sedimentary sinks as a resource to be examined and utilized. To do so would require locating and mapping zones of intense deposition: investigation of the behaviour of waste material as it becomes deeply buried; and an examination of the economics of transporting material to sinks distant from its source. All these measures are feasible.

Demarcating present-day depositional sinks would require efforts similar to surveys already in progress. On the periphery of the sediment fan off-lying a major river, sedimentation is concentrated at one point or other for millennia at a time. The controlling factors are the development of subaqueous valleys canalizing density currents[11] and the slumping of accumulated masses. Within the trenches the slopes rarely show great thicknesses of sediment (Fig. 2), because this is carried by slumping to the trench floor or to sediment traps formed by the flank benches. Profiles suggest that the flank accumulations are temporary; disposition into the mantle takes place finally at the trench bottom (Fig. 2, *A* and *C*).

The behaviour of waste material as it becomes buried is important as regards the effect on marine life of the expulsion of water from sediments containing waste matter, including the common metals. The effects would presumably be minuscule compared with those resulting from present-day run-off from unburied refuse. Effluvia from the volcanic processes connected with the emplacement annually of 60 km³ of crust along the axis of the ocean ridge system must be immeasurably greater. It would be instructive in this regard to examine the effect on marine life of the emplacement of the metal-bearing brines in the Red Sea[12].

The cost of the investigations named would not be inconsiderable. In feasibility studies the cost of compressing waste material and its transportation to distant regions must also be taken into account. Facilities have already been operated at which municipal refuse is compacted to the stage at which its density is greater than 1·1 g/cm³. Its texture becomes that of building blocks. To judge by the experience of the petroleum industry, barge transportation of compressed refuse across an ocean would cost less than its piecemeal transportation 100 km by road or train. The organization of bulk transportation would bring into play the economies of mass production, as against the extraordinarily inefficient means of disposal at present available. These cost one nation £1,875 million ($4·5 billion) per annum[1], and cannot be made effective.

In an age in which waste material is mass-produced, only a mass-production disposal technique can be successful. The tectonic sinks are apparently so capacious as to take care of any conceivable quantity of material. The principal benefit of this form of disposal would be that its effect on the environment would not be cumulative. The ultimate effect to be expected would be the discovery of a distinctive, and perhaps, puzzling, suite of metamorphic rocks.

Absorption Spectrum of Water Vapour in the Region of 23 cm^{-1} at Low Temperatures

The absorption of submillimetre radiation by the Earth's atmosphere is dominated by the pure rotation spectrum of the water molecule. If we are looking at submillimetre wave spectra for evidence of the presence in the atmosphere of species other than monomeric water, then regions in the gaps between the more intense lines of this molecule are of particular importance. One of these gaps where a

number of measurements have been made is in the vicinity of 23 cm^{-1} (435 μm wavelength). Here the absorption as measured by recording solar radiation coming through a slant path in the atmosphere is too great to be explained by considering only monomeric water vapour lines and magnetic dipole oxygen lines[1]. It is therefore of interest to investigate the cause of the additional absorption by making laboratory measurements.

Observations which use the Sun as a source necessarily involve absorption paths that are, in part, at lower temperatures than are usual at sea level and below the temperatures at which laboratory investigations have so far been made, so we have extended the latter to a lower temperature. An additional incentive to do this work comes from an interest in the hypothesis that the anomaly might be explained if we included in our considerations absorption by multimeric water molecules. We believe that the results give positive evidence in favour of their existence.

Fig. 1 shows spectra of a fifty metre path of water vapour at a pressure of 0·4 torr (approximately 5×10^{-5} MN/m^2) with an overpressure of two atmospheres of argon (approximately 0·2 MN/m^2). The observations were made in a multipass absorption cell and results are given for gas temperatures of 248 K and 298 K. From these it can be seen that the spectrum recorded at the lower temperature shows features in the vicinity of 23 cm^{-1} which are significantly stronger than in the spectra recorded at the higher temperature. These cannot be attributed to monomeric water pure rotation lines, of which the positions are indicated. We also show the energy level of the lower state of the transition for the monomer lines and from these values we can understand why some of them, for example that at 30·5 cm^{-1}, have such a marked decrease in intensity at the lower temperature. In contrast, several features, including the one singled out at 23 cm^{-1}, increase at the lower gas temperature.

The 23 cm^{-1} feature may be identified with an observation in the same region in earlier laboratory results. Here there was a slight indication of absorption in a 28 metre path of water vapour at a pressure of 4 torr and a temperature of 273 K[2]. The fact that the feature is now so much stronger brings out the importance of using an overpressure to broaden the lines. We also mention an unassigned feature at 22·9 cm^{-1} observed in a path of 180 m at a pressure of 15 torr and a temperature of 293 K[3].

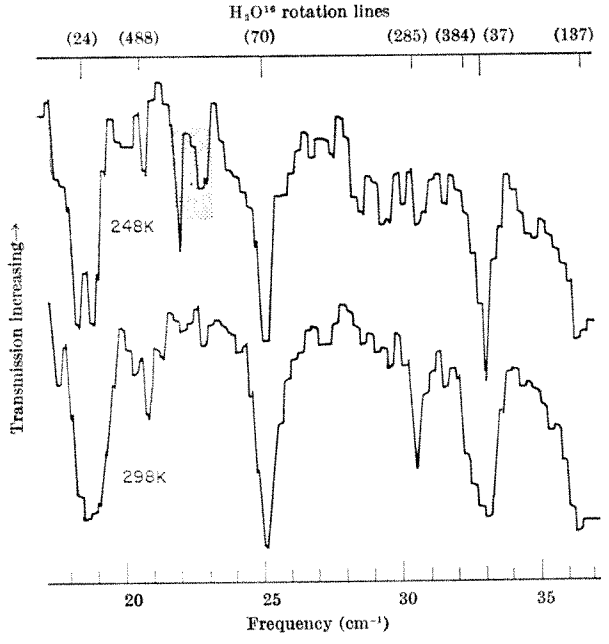

Fig. 1. Transmission of a mixture of water vapour and argon at two temperatures. The numbers in parenthesis beside the marks indicating the frequencies of the pure rotation water lines give the energies in cm^{-1} of the lower states of the lines. Path length, 50 m; water vapour pressure, 0·4 torr; argon pressure, 1,400 torr; spectral resolution, 0·5 cm^{-1}

It seems to be most unlikely that a stable complex between argon and water could be formed at the pressures we used and that it would have a spectral feature resembling something observed in the atmosphere. We submit therefore that these spectra are a further indication of the existence of multimers of water in the vapour phase, of which the dimer seems to be the most likely species[4].

We thank Dr R. F. Calfee of ESSA Research Laboratories for the use of his theoretical data on water monomer lines.

Low Threshold Laser Action of a Rare Earth Chelate in Liquid and Solid Host Media

Several authors have reported on the fluorescence line-spectra exhibited by certain rare-earth chelates, and suggested their relevance in the search for new laser systems[1–4]. Both europium and terbium chelates have been used in pulsed liquid–lasers operating at room temperature with input energy thresholds in the range of 200 to 2,000 J. The europium system operated on the 612 nm (orange) line of the chelate $Eu(BTA)_4Py$ (BTA = benzoyl trifluoroacetone, Py = pyrrolidine), whereas the terbium system, based on $Tb(TFA)_3$ (TFA = trifluoroacetylacetone) gave an output in the green region at 547 nm (refs. 5–7).

Transparent organic polymers, such as poly(methyl methacrylate) (PMMA), polystyrene, polycarbonates and acrylonitrile-based copolymers, could in principle be used as host media for laser-active chelates. It has been reported that $Eu(TTA)_3$ and $Tb(TTA)_3$ (TTA = thenoyl trifluoroacetone) have exhibited stimulated-fluorescence phenomena in very thin PMMA fibres cooled to 77 K (refs. 8–10). The technique used in the preparation of fibres, however, cannot readily be adapted to the manufacture of chelate-doped polymer rods. Also, I find that the method commonly used for preparing massive specimens of PMMA (and some other polymers) where a solution of the additive (in this case chelate) in monomer is treated with benzoyl peroxide to initiate the polymerization reaction cannot be used here, because the chelates are oxidized to non-fluorescent products in these conditions. Accordingly, I have devised a technique in which gamma radiation is used to initiate the polymerization. This gives polymer specimens of good optical quality, with little or no degradation of the chelate additive[11].

Having unsuccessfully tested a number of specially prepared europium and terbium chelate-doped polymer rods for stimulated fluorescence and other effects, I have recently investigated a neodymium-containing chelate using both PMMA and an organic liquid as host media. I had assumed, in view of the low-threshold capabilities of established neodymium systems (Nd in glass, selenium oxychloride and so on), that the neodymium chelate would be more compatible with the low-power pumping cavity used in this work (800 J maximum).

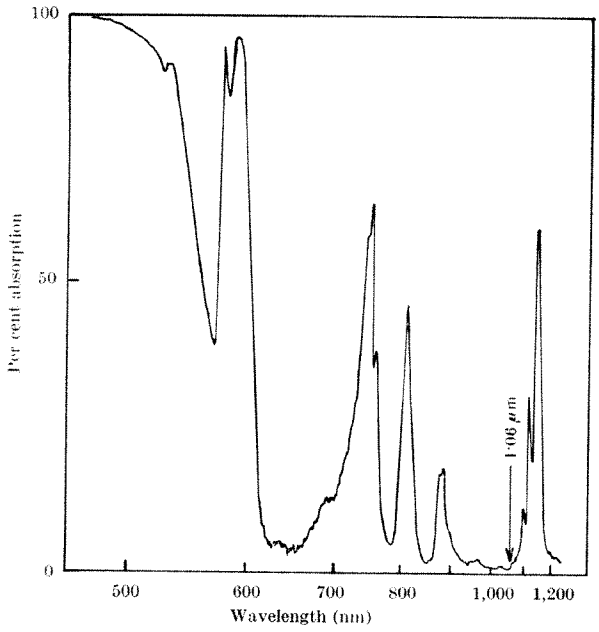

Fig. 1. Absorption spectrum of 10 mmole $l.^{-1}$ solution of "didymium" chelate in 1: 9 acrylonitrile/CCl_4 solvent. 10 cm path-length cell.

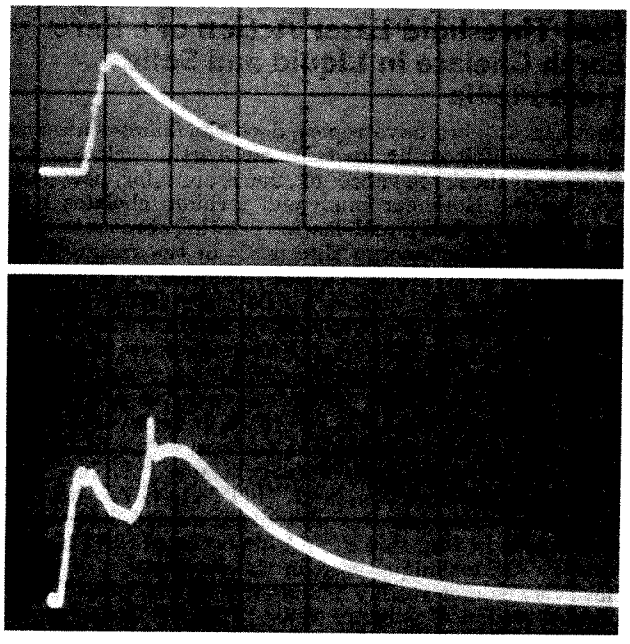

Fig. 2. Upper trace, flash pulse only at 200 J input. Lower trace, fluorescence pulse from chelate solution at 200 J. Horizontal sweep 100 μs/cm.

The chelate was prepared by complexing "didymium" chloride (presumed to contain about 70 per cent $NdCl_3$) dissolved in alcohol with TTA in the presence of pyrrolidine, using proportions of the reactants which would favour the formation of the tetra-chelated product $(Nd(TTA)_4Py$ (didymium chloride : TTA : Py; 1 : 4 : 4 molar). Initially, trials were carried out using a 10 mmole/l. solution of the chelate in 1 : 9 acrylonitrile/carbon tetrachloride solvent, having first established that this particular solvent is transparent in the region of the neodymium laser wavelength (1·06 μm) and that the absorption spectrum of the resulting solution exhibits a "window" in this region (Fig. 1). Samples of the solution, maintained at room temperature and held in glass cells of various dimensions, were excited by means of a 75 mm arc-length flash tube using a spherical-mirror cavity similar to that described by Samelson *et al.*[5]. The fluorescence pulses were detected by a fast rise-time silicon photodiode and displayed on a 50 MHz bandwidth oscilloscope. In the early experiments extraneous light from the flash tube was filtered out using an infrared pass filter, but this was later found to be unnecessary.

The fluorescence pulses obtained from the neodymium chelate solution exhibited irregularities, which I attribute to stimulated fluorescence and laser–oscillation effects when the pumping flash intensity exceeded a critical threshold value. Also, the shape of the time-resolved irregularities depended on the degree of optical feedback present in the glass cell used to contain the solution. Using a minimum feedback system, in the form of a 12 cm path-length × 7 mm internal diameter cell fitted with flat non-metallized end windows, the pulse exhibited a secondary (stimulated) peak occurring about 100 μs after the pumping flash peak. On increasing the feedback by adding an external fully aluminized 10 cm focal-length concave mirror the secondary peak showed superimposed "spikes", which I attribute to heavily damped relaxation-oscillations (Fig. 2). On adding a second (partially transmitting) mirror at the output end of the cell, however, the second peak and spikes could no longer be observed, possibly as a result of the generation of spurious laser modes falling outside the acceptance cone of the photodiode. Finally, well defined relaxation oscillations were observed using an 11 cm cell of 8 mm inner diameter having approximately hemispherical non-metallized ends, with a pumping threshold of about 120 J (Fig. 3). The oscillations in the latter case were probably associated with complex total internal reflexion modes, and it seems probable that the threshold level would be considerably reduced in a properly designed cell capable of axial-mode operation.

The secondary-peak phenomenon (Fig. 2) was again observed using 8 cm × 8 mm PMMA rods containing 20 mmoles/l. of the "didymium" chelate, but the

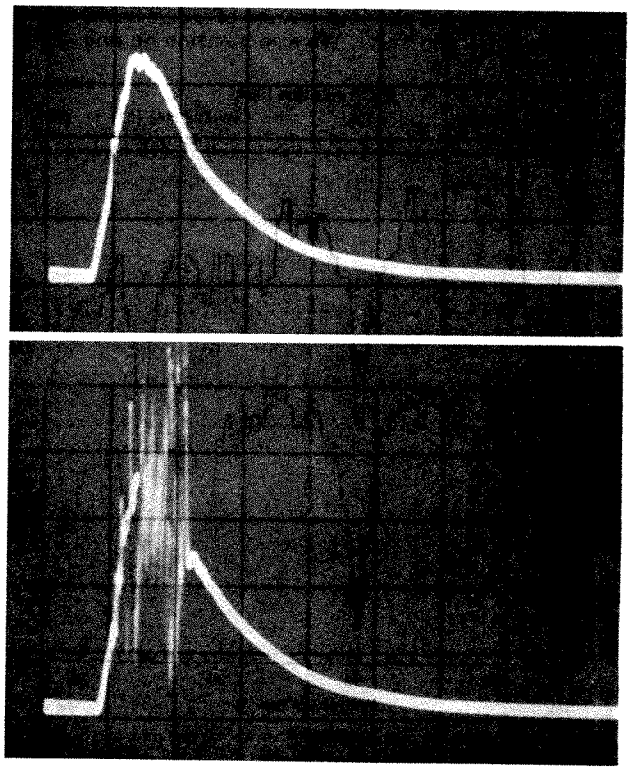

Fig. 3. Fluorescence pulses. Upper trace, 110 J input. Lower trace, 120 J input (threshold). Horizontal sweep 50 μs/cm.

threshold in this case was about 200 J and spiking phenomena were not so pronounced. PMMA is not the best polymer host for this particular chelate, however, because it absorbs in the 1·06 μm region. The losses in an 8 cm rod would amount to about 70 per cent per double-pass. It is possible that some of the acrylonitrile based copolymers would be more suitable.

The liquid laser system described here is probably comparable as regards operating temperature (300 K) and threshold with the inorganic neodymium systems ($Nd/SeOCl_2$, $Nd/POCl_3$) already in use, but has the advantage that the solvent is non-corrosive (although moderately toxic) and is therefore more adaptable to continuous-flow equipment. Also, the utilization of pumping energy is probably unusually efficient, for energy can be transferred to the Nd^{3+} ion both directly (Nd^{3+} ion absorption band, 570–610 nm, Fig. 1) and via the chelate ligands (450–580 nm band, Fig. 1). This being so, it is possible that a continuous-wave laser could be developed. The successful demonstration of stimulated processes in the neodymium chelate/PMMA system suggests that further research on the use of polymers as hosts may be productive.

BIOLOGICAL SCIENCES

Selective Constraints on Amino-acid Substitutions during the Evolution of Proteins

RECENTLY, several workers have suggested that during the evolution of proteins most amino-acid substitutions (in the sense of mutations that have spread to fixation) have been neutral in selective value[1–4]. These views have not received unanimous support[5,6]. It seems appropriate, therefore, to examine the pattern of substitutions in order to detect any possible influences of natural selection. I here analyse the relationship between the frequencies of particular substitutions and the chemical properties of the amino-acids concerned in them.

For our purpose we need an objective classification of the chemical properties of amino-acids. Fortunately, this has been provided by Sneath[7], who has constructed a "numerical taxonomy" of amino-acids. On the basis of 134 chemical characters he drew up a matrix (of $D = 1 - S_{SM}$[8]) in which every amino-acid was compared with every other, and each comparison was represented by a value of D indicating the degree of chemical dissimilarity between them.

Data on the relative frequencies of amino-acid substitutions can be obtained from the compilations of Dayhoff (ref. 9: Fig. 9–3, page 76). She tabulates the numbers of substitutions, between particular pairs of amino-acids, that have been observed during the evolution of a "representative" series of proteins (cytochrome *c*, haemoglobin, myoglobin, virus coat proteins, chymotrypsinogen, glyceraldehyde-3-phosphate dehydrogenase, clupeine, insulin and ferredoxin). In my analysis these numbers have been corrected both for the frequencies of amino-acids (given in Fig. 9–6 of ref. 9, page 78) and for the different probabilities of mutational changes between amino-acids imposed by the genetic code.

The calculation of a corrected number proceeds as follows. I consider only those substitutions that can result from a single nucleotide replacement (that is, only those proceeding from one-step mutations). Let N_{AB} represent the number of substitutions between amino-acid A and amino-acid B recorded by Dayoff (note that this represents the number of substitutions A→B plus the number of substitutions B→A). Let the frequency of A in the proteins considered be a and the frequency of B, b. Let the relative probability of the mutation A→B, according to the genetic code (assuming equal frequencies of synonymous codons and excluding nonsense codons from the analysis), be p_{AB}, and the probability of the mutation B→A be p_{BA}. These probabilities may be unequal because different amino-acids are coded by different numbers of synonymous codons. The corrected number of substitutions is then

$$R_{AB} = \frac{N_{AB}}{ap_{AB} + bp_{BA}}$$

When N_{AB} is zero, it is arbitrarily given a value of 0·50 in order to avoid loss of information. The value of R_{AB} is then likely to be an overestimate, the error being in the right direction. A corrected number has been calculated in this manner for each of the 75 one-step mutations permitted by the genetic code. Each number is proportional to the average rate of evolutionary substitution between a particular pair of amino-acids.

Fig. 1 is a scatter-diagram showing the relationship between the corrected numbers of substitutions (R) and the values of D obtained by Sneath[7]. Each spot represents a pair of amino-acids. There is an obvious negative correlation, indicating that substitutions which involve relatively small chemical changes are very much more frequent than those involving relatively large changes. This relationship can be caused only by constraints imposed by natural selection.

There is a difficulty in testing the significance of the correlation because the spots are not statistically independent of one another. It can be overcome by allowing 18 degrees of freedom (for the 20 amino-acids) rather than 73 (for the 75 spots). In spite of this restriction, the correlation is still highly significant (using logarithms of R; $r = -0{\cdot}652$, $P \ll 0{\cdot}01$). Because the true number of degrees of freedom is certainly greater than 20, the significance is probably well below 0·1 per cent. The correlation is not an artefact arising from the combination of heterogeneous data. If the proteins are treated individually, they give similar results (unpublished).

The observation that rates of substitution are dependent on the magnitude of chemical differences between the amino-acids is not a new one. Zuckerkandl and Pauling[10] have drawn the distinction between "conservative" substitutions producing little chemical change and "radical" substitutions producing gross chemical change. They have pointed out that the former are the more common. The advantage of the present method, however, is that it allows the relationship to be quantified. It shows that the degrees of "conservatism" and the rates of substitution are quite precisely related, and it confirms the view of Zuckerkandl and Pauling that there is a continuous, but wide, spectrum of different rates.

This is important because it invalidates several later, and less critical, studies of protein evolution. For example, King and Jukes[1] have argued that most substitutions are selectively neutral. For several proteins they have plotted the number of changes per site against the number of

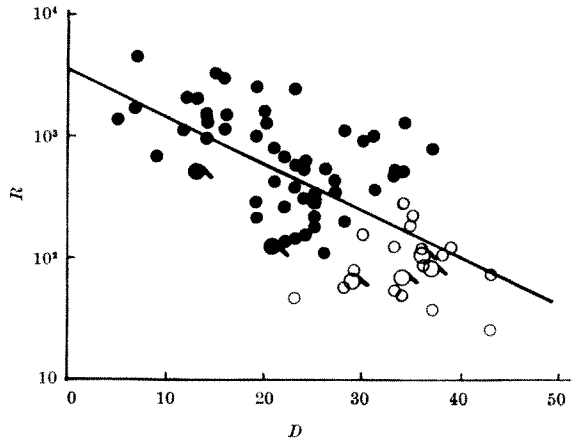

Fig. 1. The relationship between corrected number of substitutions (R) and chemical difference (D)[7] for the 75 amino-acid interchanges permitted (in one mutational step) by the genetic code. The values of R are derived from a "representative" series of proteins (see text). Open circles represent substitutions that were not observed in the proteins examined. To avoid loss of information the number of substitutions in each of these cases was assumed to be 0·50, so that their values of R are likely to be over-estimates. Large circles with tails represent substitutions involving cysteine. The negative correlation is highly significant ($r = -0{\cdot}652$, $P \ll 0{\cdot}01$, using logarithms of rates). The sloping line shows the regression of R on D.

sites having the specified number of changes. After making allowance for a (somewhat arbitrary) number of "invariant" sites, they conclude that the remainder fit the Poisson distribution. They regard this apparent correspondence as evidence that most of the substitutions occur randomly. The Poisson distribution applies to events that have a low but constant probability. The analysis set out above, however, demonstrates that the probabilities of substitutions vary greatly in relation to the chemical properties of the amino-acids. We must conclude that the apparent correspondence reported by King and Jukes is an accident. This criticism also applies to the work of Fitch and Margoliash[11,12], who have based their arguments about "concomitantly varying codons" on an apparent correspondence with the Poisson (although in this case certain "hypervariable" sites were also excluded).

The relationships demonstrated in Fig. 1 do not by themselves eliminate the possibility that most substitutions are selectively neutral. It is conceivable, though unlikely[5], that the selective constraints indicated by the figure merely ensure that the probability of a neutral substitution is very much reduced when the chemical differences are great. Taking this view, which corresponds to those of King and Jukes[1] and Kimura[2], one is forced to conclude that if most substitutions are selectively neutral, most mutations are not. In Fig. 1 the average (geometric mean) rate of substitution is 362 (95 per cent confidence limits, 207 and 630, assuming 18 degrees of freedom). The maximum rate, which according to the argument just stated should be the rate of neutral substitution ($D = 0$), is about 3,320 (95 per cent confidence limits, 940 and 11,830, assuming 18 degrees of freedom). The average rate is thus only about one-ninth of the "neutral" rate (95 per cent confidence limits, 1/3 and 1/29, assuming 18 degrees of freedom). We must conclude that at least 85–90 per cent of the mutations causing a change of amino-acid are, on the average, selectively disadvantageous. This result is incompatible with Kimura's own argument, for he has deduced that more than 50 per cent of such mutations are neutral[4].

King and Jukes[1] have estimated that 5–10 per cent of mutations are neutral. At first sight my own calculations might seem to support them, but they do not. Fig. 1 takes into account only one kind of selective constraint, and there are many others. There are, for instance, limitations imposed by the kind of protein in which the substitutions occur[6], by the position of the amino-acid in the protein[10,13], and by the type of organism in which the protein is foun When all such factors are taken into account it seen likely that our estimate of the average proportion "neutral" mutations will be nearer 0·1 per cent than per cent.

Zuckerkandl and Pauling[10] have remarked that "a parently chemists and protein molecules do not share tl same opinions regarding the definition of the most pron inent properties of a residue". The opinions of tl protein molecule are made manifest in the pattern evolutionary substitutions. We have to make chemic sense of them and the method of analysis promises make this possible.

Sneath's classification is based on 134 characters, of which are given equal weight. From the evolutiona point of view, however, it is clear that the individu chemical properties of the amino-acids are not all equal importance. It is therefore possible to modify tl classification by weighting characters so as to maximi the relation between R and D. The weights of individu characters would then be a direct measure of the importance to the function of the protein.

Substitutions involving cysteine seem to depa systematically from the regression line given in Fig. (the cysteine pairs are shown as large circles with tails If the chemical characters of cysteine are weighted reduce the departure from the regression, the ability form disulphide bonds is given a high value. In oth words we could, without previous knowledge of prote chemistry, have predicted the importance of the disulphi bond.

The method still has to be developed, but some interes ing results can be expected, particularly if the greate possible number of chemical properties can be incorporate into the classification. It is satisfying that the studer of evolution can perhaps contribute to solving th problems of the chemist.

I thank Mr T. H. Day, Mr R. Elton, Dr D. T. Parkin Professor A. Robertson, Professor J. Maynard Smith, E. Southern, and Professor P. M. B. Walker for discussion Miss Yvonne Pryde for technical help; and the Scienc Research Council and the Nuffield Foundation for financi aid.

F(ab')$_2$-like Fragments from Severely Burned Patients provide a New Serum Immunoglobin Component

INTEREST in immunoglobulin fragments in serum centre around their antigenic sites which stimulate aut antibody[1], and the insight they provide into the met

bolism of immunoglobulins. They also have the potential to alter host immune defence mechanisms. For example, the $F(ab')_2$ fragment prepared *in vitro* from IgG is less effective than intact IgG in protecting animals injected with pathogens[2], in aiding phagocytosis[3,4] and in clearing bacteria from the blood stream[2,5]. Also, $F(ab')_2$ fragments are non-cytotoxic in the presence of complement[6,7] and enhance the growth of tumours[8,9]. Because severely burned patients have larger than normal concentrations of proteolytic enzymes[10] and immunoglobulins in their serum[11–13], we regarded them as potential models for *in vivo* degradation of immunoglobulin, and examined serum from forty patients with 3–70 per cent body surface area full-thickness burns for immunoglobulin fragments. The following report identifies for the first time a serum $F(ab')_2$-like fragment in severely burned patients.

Immunoelectrophoretic[14] patterns of sera developed with rabbit anti-whole human serum prepared in our laboratory showed a new precipitin arc (Fig. 1*a*). Antisera to IgG, IgA, IgM_1 and IgM_2 (Immunology Inc.) were also used, and only anti-IgG produced the new arc (Fig. 1*b*) as well as its characteristic arc. This indicated that the new serum component was related to IgG; hereafter in this report it is designated $F(ab')_2$-burn.

Both the time interval after the burn and the severity of the burn determined whether $F(ab')_2$-burn was present. Its characteristic arc was seen in patterns of sera obtained only on days 6 to 16 after the burn. When patients were grouped according to percentage body area covered with full-thickness burn, the proportion of each group with serum $F(ab')_2$-burn was as follows: >39 per cent, 11/11; 18–39 per cent, 13/20; <18 per cent, 0/9.

$F(ab')_2$-burn was isolated from serum. The precipitate obtained with 55 per cent saturation $NH_4)_2SO_4$ was dialysed against *p*H 8·0 Tris/HCl buffer (Sigma) and distilled water, placed on a column of 'Sephadex G-200' (Pharmacia) and fractions were collected during 0·1 M stepwise addition of 0·1 M–0·5 M Tris/HCl buffer. The IgG peak from burned patients' serum had a large trailing shoulder in contrast to the IgG peak from normal serum. The trailing shoulder was fractionated using a column of 'Sephadex G-150' which produced separation of IgG and $F(ab')_2$-burn. No $F(ab')_2$-burn fragment was obtained when IgG from normal serum was fractionated using 'Sephadex G-150' in the same way.

Ultracentrifugation of the isolated $F(ab')_2$-burn in 10–40 per cent sucrose gradients, at 27,500 r.p.m. for 24 h. suggested that it was similar in size to $F(ab')_2$ fragments. For further comparison, therefore, $F(ab')_2$ fragments were prepared from IgG by pepsin degradation[15,16] at *p*H 3·5 for 48 h. using 50 mg of IgG/mg of pepsin (Worthington), and 0·05 N HCl and NaOH to adjust the *p*H. $F(ab')_2$ was isolated by 55 per cent saturation $NH_4)_2SO_4$ and 'Sephadex G-150' as before.

Immunoelectrophoresis of $F(ab')_2$ gave a precipitin arc identical to the $F(ab')_2$-burn arc in serum when developed with anti-$F(ab')_2$ prepared in our laboratory (Fig. 1c). When patterns of serum from burned patients were developed with anti-Fc, the IgG arc was still present, but the $F(ab')_2$-burn arc was not (Fig. 1*d*). This indicated that $F(ab')_2$-burn did not have Fc antigenic determinants, which is also characteristic of $F(ab')_2$. The IgG arc developed with anti-Fc also showed anodal splitting, which suggested the presence of a free Fc-like fragment. When IgG was mixed with either $F(ab')_2$-burn or $F(ab')_2$ and developed with anti-IgG, the pattern was similar to the burned patient's serum shown in Fig. 1*b*. Additional patterns developed with antisera to kappa or lambda chains (Melpar Inc.) also had the characteristic $F(ab')_2$-burn arc indicating the presence of these light chains in $F(ab')_2$-burn.

Ultracentrifugation in a model E Spinco ultracentrifuge provided further evidence for the similarity between $F(ab')_2$-burn and $F(ab')_2$. Each fragment migrated in a single homogeneous peak, 10 mg/ml. 0·05 M NaCl, 59,780 r.p.m., and corrected $s_{20,w}$ values[17] were 5·23 for $F(ab')_2$-burn and 5·17 for $F(ab')_2$.

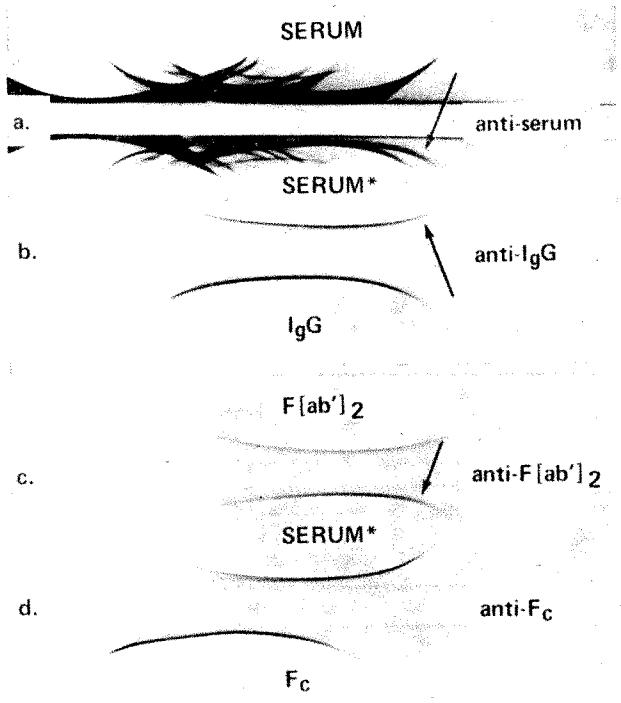

Fig. 1. Immunoelectrophoretic patterns with an arc (arrow) characteristic of an $F(ab')_2$-like component in serum* from a patient 8 days after a severe burn. *a*, Anti-human serum demonstrates the new component in the patient's serum* on day 8 (lower) but not in serum on day 20 (upper); *b*, anti-IgG shows the $F(ab')_2$-like component in serum* (upper) cathodal to the faint IgG which is compared with an isolated IgG (lower); *c*, anti-$F(ab')_2$ shows no IgG arc with the $F(ab')_2$-like component in serum* (lower) similar to an isolated $F(ab')_2$ (upper); *d*, anti-Fc detects the IgG but not the $F(ab')_2$-like component in serum* (upper). The cathode is to the right.

$F(ab')_2$-burn and $F(ab')_2$ were reduced[18] with cysteine and ultracentrifuged in sucrose density gradients. The Fab'-burn and Fab' reduction products were approximately half the size of the original molecules as indicated by their sedimentation at the rate of a 3·5 S Fc control[19]. These results further indicated the similarity of $F(ab')_2$ and $F(ab')_2$-burn.

Therapy in the University of Michigan Burn Unit probably contributes to formation of $F(ab')_2$-burn. Patients are actively immunized with *Pseudomonas aeruginosa* vaccine[20,21] (prepared at the unit) shortly after admission. Passive immunization with 1/4–1 U of plasma from immunized human donors usually begins after 1–4 days. The increased level of immunoglobulins, plus the increased proteolytic activity, probably produces enough $F(ab')_2$-burn to be detectable in serum, even though the half-life of $F(ab')_2$ is only 10–14 h[22].

Isolated $F(ab')_2$-burn possessed the antibody activity characteristic of $F(ab')_2$. Tube agglutination (Table 1) showed that the anti-*Pseudomonas* titre of $F(ab')_2$-burn isolated from serum of a burned patient was similar to titres of the whole serum, IgG isolated from the serum, and $F(ab')_2$ prepared from the IgG. This patient had received only active immunization, and $F(ab')_2$-burn was therefore derived from endogenous IgG. Whether $F(ab')_2$-burn results from an abnormal mode of catabolism or an accelerated physiological process is not known. According to current concepts of immunoglobulin metabolism, it is unlikely to be a synthetic product. It is not C-reactive protein. Patients did not receive $F(ab')_2$-burn by passive immunization, for its characteristic arc was not detected in immunoelectrophoretic patterns of four therapeutic plasmas.

It is unlikely that $F(ab')_2$-burn was produced *in vitro* during or after bleeding. Sera were collected and immunoelectrophoresis was begun within 1 h of bleeding, and $F(ab')_2$-burn was absent in sera from lightly or severely burned patients before 6 or after 16 days. As an additional control, the proteolytic enzyme inhibitor 'Trasylol' (Bayer AG), which inhibited *in vitro* degradation of sera from burned patients[23], was placed in needles, syringes and tubes used to collect blood from patients with an 80 per cent full-thickness burn and a 40 per cent variable-thickness burn. The new immunoelectrophoretic arc was still present even though the patients' blood did not clot. We could reproduce the arc artificially but only after a minimum of ten cycles of freezing and thawing of serum or IgG. Similar *in vitro* degradation of immunoglobulin during storage has been reported by others[24,25]. Immunoelectrophoretic artefacts were prevented by avoiding antigen or antibody excess, as determined in preliminary titrations. Any questionable pattern was developed at least twice to rule out errors in technique. The new immunoelectrophoretic arc was not found in thirty fresh sera of randomly selected control patients with a wide variety of diseases. It has been pictured in other human sera and globulin preparations[26–29], but additional characteristics were not correlated. The characteristic arc in burned patients' serum has been correlated with similar arcs in immunoelectrophoretic patterns of serum from patients with multiple myeloma and of urine from patients with systemic lupus erythematosus[30].

Table 1. ANTIBODY ACTIVITY OF AN $F(ab')_2$-LIKE SERUM IMMUNOGLOBULIN FROM A BURNED PATIENT

Serum or globulin	Titre 2*	4	8	16	32	64	128	256	512
Burned patient's									
$F(ab')_2$ like immunoglobulin	+	+	+	+	+	+	+	+	0
Serum	+	+	+	+	+	+	+	+	+
IgG	+	+	+	+	+	+	+	+	+
$F(ab')_2$	+	+	+	+	+	0	0	0	0
Non-burned patient's									
Serum	+	+	0	0	0	0	0	0	0
IgG	+	+	0	0	0	0	0	0	0
$F(ab')_2$	0	0	0	0	0	0	0	0	0

The agglutinin titre of the serum immunoglobulin is compared with that of: whole serum, the serum's IgG, and $F(ab')_2$ prepared from the IgG, of burned and non-burned patients.
The burned patient was injected with *Pseudomonas aeruginosa* vaccine; the control non-burned patient was not. The vaccine was used as antigen in determining titres.

* Undiluted serum or 10 mg of globulin/ml. of 0·85 per cent NaCl.

This report therefore provides strong evidence that the serum of severely burned patients contains an immunoglobulin component comparable with the enzymatically produced $F(ab')_2$ fragment. It is characterized by a specific cathodal arc in immunoelectrophoretic patterns of serum, and it must be differentiated from a similar fragment which may be produced *in vitro*.

We thank Dr Irving Feller for his cooperation, Carl Pierson for liaison work and Samuel Broder for control sera. Dr W. W. Coon provided 'Trasylol' and Dr J. T. Cassidy provided anti-F_c serum. This work was supported by a US National Science Foundation institutional fund through the Horace H. Rackham School of Graduate Studies. C. B. G. is a James Scholar of the University of Illinois Medical School.

F_K-*lac*, an Episome with Unusual Properties found in a Wild Strain of a *Klebsiella* Species

F-PRIMES, episomes consisting of an F-factor joined to a fragment of the bacterial chromosome, arise spontaneously in Hfr males of *Escherichia coli*, and are easily selected because of their infective properties[1]. It is therefore surprising that only two such episomes have been reported from natural sources: F_0-*lac* found in a strain of *Salmonella typhosa*[2] and P-*lac* found in *Proteus* species from a single hospital[3,4]. Both of these episomes were recognized because their lactose-negative hosts had become lactose-positive (Lac^+), and both are highly infective and show mutual interference with F-factors of *E. coli*, that is the presence of one excludes the other.

We describe here a third F-*lac* of natural origin possessing some unexpected properties. It was discovered in a normally Lac^+ *Klebsiella* species, carries an active repressor gene of the type possessed by *fi*$^+$ R-factors, and shows mutual exclusion with F in *E. coli*, but is completely unable to promote conjugation.

The host strain (V9A), a *Klebsiella* provisionally identified as a member of *K. aerogenes*, came from faeces sampled from a wild vole population (*Microtus agrestis* L.) in a long-established Scottish Forest (area C-1a of the Carron Valley vole population[5]). This source was examined in a search for Enterobacteriaceae from environments with no known history of antibiotic treatment. *Klebsiella* V9A is resistant to two antibiotics, tetracycline (Tc) at 40

μg/ml. and ampicillin at 20 μg/ml., and is Lac+ like other *Klebsiella*.

V9A gave no transfer of resistance to *E. coli* in overnight matings, but transfer of Tc-r was achieved with the help of either an F-type or an I-type transfer factor, previously introduced into the donor. In typical experiments (Table 1) the derepressed I sex factor transferred itself with high efficiency, while F-*gal* was transferred some 2,000 times less frequently in comparable tests. Both sex factors transferred Tc at about 0·4 per cent of the rate of sex factor transfer. This and other experiments show that Tc resistance is caused by a plasmid gene. Ampicillin resistance was not transferred, but indirect evidence suggests that it is also extra-chromosomal. Work on these resistance genes will be published elsewhere.

Table 1. TRANSFER OF SEX FACTORS AND TETRACYCLINE RESISTANCE FROM *Klebsiella* STRAIN V9A TO *E. coli* K12

Sex factor introduced into *Klebsiella*	Mating time (h)	Transfers per K12 recipient of: Sex factor	Tc-r	Transfer ratio Tc/sex factor (per cent)
None	16	–	$< 10^{-9}$	–
F-*gal*	3½	5×10^{-3}	2×10^{-7}	0·4
I*drd* Kan	3½	2×10^{-1}	7×10^{-4}	0·3

For the first mating, fully grown broth cultures of donor and recipient were diluted 10^{-3} into broth and incubated overnight at 37° C. For the other two matings, log phase donor cells at about 2×10^{9}/ml. and a fully grown recipient culture were diluted together 10^{-1} into broth and incubated 3·5 h without aeration. Various dilutions were then spread on selective plates to measure transfer and recipient cell frequencies. Streptomycin was used to counter-select against the donor strain. The sex factors were F-8 (F-*gal*)[1], in a Gal- mutant of V9A, and R144 *drd*, a derepressed mutant of a *coli* I-type R-factor[8], conferring resistance to kanamycin (Kan), supplied by Dr Elinor Meynell.

The F-*lac* particle in V9A was discovered by a happy chance, when MacConkey agar containing tetracycline and streptomycin was used to select Tc-r recipients in a cross between V9A carrying F-gal and a Lac- Gal- streptomycin-resistant strain of *E. coli* K12. To our astonishment, Lac+ as well as Lac- colonies were obtained. Both types were found to be Tc-r recipient colonies, but the sex factor F-*gal* was only present when Lac+ was not, suggesting that the two particles show mutual exclusion (that is, they cannot coexist) in the recipient strain, although they must have been present together in the *Klebsiella* donor. We ruled out the possibility that this Lac+ particle might have been introduced into V9A along with F-*gal* from its original (Lac+) K12 donor, by starting with another sample of V9A and infecting it with F-*gal* from a Lac- K12 strain. The new V9A/F-*gal* was able to transmit Lac+ in the same way as the previous V9A/F-*gal* strain.

Table 2. EFFECT OF RESIDENT Lac+ PARTICLE ON ABILITY OF K12 TO ACCEPT F-*his*

Episome in K12 recipient strain	Per cent of recipients infected with F-*his* in one hour Test 1	Test 2	Lac state of infected recipients
None	65	19	–
Lac+ from V9A	4	0·4	all Lac-
Relative efficiency	6 per cent	2 per cent	

Log phase donor cells (K12/F-*his*) at 2×10^{8}/ml. and a fully grown recipient culture were diluted together 10^{-1} into warm broth and incubated 1 h at 37° C without aeration. Dilutions were then spread on selective plates to measure transfer and recipient cell frequencies. Independent Lac+ infected recipient lines were used in the two tests, and twenty His+ clones from each were tested for the retention of Lac+. Relative efficiency of transfer is measured as the ratio of the proportion of His+ recipients in the Lac+ mating to the proportion in the Lac- mating, calculated as a percentage (for example, $4 \times 100/65$ gives 6 per cent).

In further matings of V9A/F-*gal* to K12 strains we were able to select recipient K12 clones which had received only the Lac+ particle. Such clones were resistant to F-specific phage (f2) and were unable to transfer Lac+ further. The recipient strain was also His-, and its ability to accept an F-prime (F-*his*) when carrying the Lac particle from V9A was compared with that of the parent (Lac-) strain by mating to a suitable K12/F-*his* donor strain under standard conditions. Table 2 shows that the presence of the *Klebsiella* Lac+ particle in the recipient reduces the frequency of *F-his* acceptance to a few per cent of the normal frequency (6 per cent and 2 per cent in the two tests), while those originally Lac+ recipients in which F-*his* becomes established lose the Lac+ particle. They also become sensitive to F-specific phage. This experiment clearly establishes the occurrence of mutual exclusion between the Lac+ particle and an F-prime in K12.

Finally, two derepressed mutants of an R-factor R1, derived by Dr Elinor Meynell, were transferred into V9A, and the F-specific phage sensitivity of infected cells and their efficiency of transfer of the sex factor into K12 were compared with those of the *Klebsiella* infected with F-*gal* (Table 3). R1 is of *fi*+ type[7], that is it carries a gene *i* the product of which represses activity of its own sex factor and of F-factors, strongly reducing the efficiency of transfer.

Table 3. BEHAVIOUR OF F-*gal* AND DEREPRESSED *fi*+ R-FACTORS IN *Klebsiella* V9A

Introduced sex factor	Sensitivity to F-specific phage	Efficiency of transfer of sex factor to K12
F-*gal*	–	Low
R1 *drd* 19 (o^+i^-)	–	Low
R1 *drd* 16 ($o^c i^+$)	+	**High**

F-*gal* (F-8) was introduced into a Gal- mutant of V9A, the R1 mutants direct into V9A. R1 *drd* 19 has a sex factor which is repressible (o^+) but makes no repressor; R1 *drd* 16 makes repressor (i^+) but is not repressible (o^c)[8]. Both R1 mutants were received from Dr Elinor Meynell. Efficiency of transfer was measured by mating for 3½ h as in Table 1 and then streaking loopfuls of the mating mixture on plates which allow only recipients infected with the sex factor to grow. Each loopful was cross-streaked over a single plate in the usual way for obtaining single colonies, so that several dilutions could be observed. All plates could be unequivocally classified as showing transfer at low efficiency (a few colonies) or high efficiency (very many colonies, with confluent growth where the loopful was first spread). Sensitivity to F-specific phage f2 was measured by spotting phage on to an overlay containing cells in soft nutrient agar (+ indicates sensitivity).

Of the two R1 mutants, *drd* 19 has been shown to produce no repressor (i^-) but to be susceptible to repressor substance (o^+) while *drd* 16 does produce repressor (i^+) but is not repressible (o^c); both R1 mutants promote their own transfer with high efficiency in K12 strains[8]. *Klebsiella* carrying F-*gal* or the repressible R1 *drd* 19 are resistant to phage f2 and transfer the infective agent with low efficiency, while clones carrying the non-repressible R1 *drd* 16 are sensitive to f2 and transfer the R1 with high efficiency. This experiment only proves that V9A carries a gene producing sex factor repressor. When the *Klebsiella* infected with an R1 mutant is mated to a Lac- K12, however, recipients carrying R1 *drd* 19 are found to be f2-sensitive and efficient donors in further matings unless they have also received the *Klebsiella* Lac+ particle, in which case they are resistant to f2 and can only transfer R1 further at low efficiency. Recipients carrying R1 *drd* 16, on the other hand, are f2-sensitive and are efficient donors of R1, whether or not they also carry Lac+. These results can only be explained on the hypothesis that the *Klebsiella* Lac+ particle itself contains a repressor gene the product of which represses the sex-factor activity of an F-factor or an *fi*+ R-factor. Only R1 *drd* 16, which has lost its repressor sensitivity, escapes this repression.

We conclude that *Klebsiella* strain V9A carries an extra-chromosomal Lac+ particle, to be named F_K-*lac*, which has an active *fi*+ repressor gene, shows mutual exclusion with F-factors in *E. coli* but not in *Klebsiella* strain V9A, and is quite unable to promote conjugation, presumably because it is deficient in some of the necessary genes. It may be noted that two different samples of vole faeces yielded V9A-type colonies carrying F_K-*lac* which were resistant to tetracycline and ampicillin, but no *Klebsiella* of the same general type not carrying the Lac episome have been found in our samples.

F_K-*lac* differs in several respects from F_0-*lac* and P-*lac*, particularly in its failure to promote conjugation, its possession of a repressor gene, and in the fact that its host is a lactose-positive species in which the episome has no apparent selective advantage. Possibly such episomes are more widespread among species of Entero-

bacteriaceae, in which their presence would not be easily recognized, than has been assumed.

Effect of Surface Charge on the Steady-state Potassium Conductance of Nodal Membrane

The curve relating membrane conductance (G_m) to membrane potential (V_m) shifts along the voltage axis with changes in concentration of external divalent ions[1–4], external pH[5] and internal ionic strength[6]. These findings are in qualitative agreement with the suggestion made by Huxley[1] that the shift may correspond to changes in the electric field resulting from changes in the membrane surface potential, ψ_0. To test the validity of the suggestion experimental shifts need to be compared with calculated changes in ψ_0 when ψ_0 is affected by various

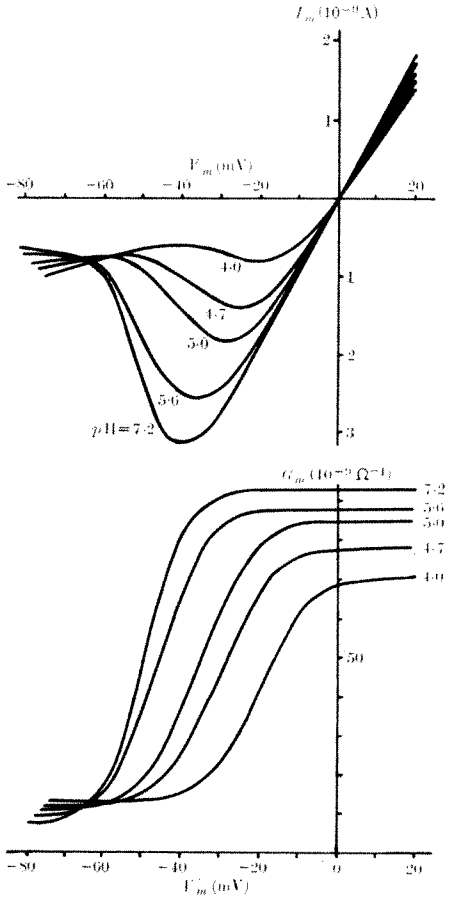

Fig. 1. Shifts of I_m–V_m curves and associated G_m–V_m curves with pH. K^+ = 100 mM; Ca^{2+} = 2 mM.

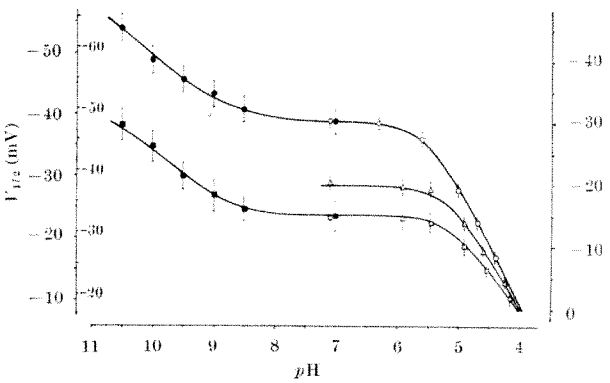

Fig. 2. Changes in $V_{1/2}$ and ψ_0 with pH. Symbols represent the mean values, with respect to nine fibres, for $V_{1/2}$. Vertical lines represent ±. Open symbols and figures on the right of the $V_{1/2}$ axis are for $V_{1/2}$ from the first set of experiments (pH 4–7); filled symbols and figures on the left of the $V_{1/2}$ axis are for $V_{1/2}$ from the second set of experiments (pH 7–10·5). ○, ●, in 2 mM Ca^{2+}; △, ▲, in 10 mM Ca^{2+}; □, ■, in 20 mM Ca^{2+}. The curves through the points which relate ψ_0 to pH were calculated by the method given in the text.

factors. While calculating ψ_0 it is essential to use the san basic assumptions concerning the charge number ar chemical nature of adsorbing groups (binding sites) the membrane surface. To this end, we studied the effe of changes in the external concentrations of H^+, Ca^{2} Mg^{2+}, Co^{2+}, Ni^{2+} and external ionic strength on stead state potassium conductance (G_m–V_m curves).

The G_m–V_m curves were calculated from steady-sta current–voltage relationship (I_m–V_m curves) obtain by the voltage-clamp method. In this method longit dinal currents along the outer surface of internodes both sides of the node under investigation were prevent by a special feedback system[7]. To obtain I_m–V_m curve a saw-tooth clamping voltage (V_m) varying at 2 mV was fed both to the input of an operational amplifi and, through a differential amplifier, to the horizont plates of a cathode-ray oscilloscope. The I_m–V_m curv thus obtained were continuous. The external potassiu concentration was 50 mM in experiments in which t ionic strength was varied; otherwise it was 100 m Solutions were kept isotonic with NaCl or Tris-H The pH was changed by the addition of small amounts biphthalate (pH 4–7) or glycine (pH 7–10·5) buffers. T ionic strength was reduced by replacing Tris-HCl wi sucrose.

Fig. 1 gives the family of I_m–V_m curves (top) and asso ated family of G_m–V_m curves (bottom) at various p values and 2 mM Ca^{2+}. At lower pH the curves shift the direction of depolarization: the V_m at which G_m half the sum of maximum and minimum, $V_{1/2}$, decreas In Fig. 2 the mean values for $V_{1/2}$ at various calciu concentrations are plotted against pH. These values we calculated from two sets of experiments: one with pH 4 and the other with pH 7–10·5. At normal [Ca^{2+}] a normal pH, $V_{1/2}$ values are scaled to the same value, for is the change in $V_{1/2}$ that matters rather than absolute values. The $V_{1/2}$-pH relationship falls into thr well pronounced regions: it has a plateau in the ran pH 8–6, rises at a pH above 8 and diminishes with a p below 6. At acid pH, Ca^{2+} has little effect on $V_{1/2}$ where at alkaline pH it has a large effect. The plateau in t $V_{1/2}$–pH relationship suggests groups of at least two typ on the membrane surface. Considering the dependen of pH effect on [Ca^{2+}] it is believed that groups of type are negatively charged and capable of binding both H and Ca^{2+} whereas the groups of type II are positive charged at pH ⩽ 7 and uncharged at pH > 7. On the ba of data presented in the literature[8] we suggested that t net surface charge is negative. Experiments with chang in ionic strength supported this suggestion: reduci ionic strength increases $V_{1/2}$ (Fig. 3), indicating an exce of net negative charge in the membrane.

While calculating ψ_0 it was assumed that the membrane phase constitutes a dielectric, or at least that its free charge density is much less than that of the solution and that there are groups of three types on the membrane surface: first negatively charged groups (at a density of σ_1) capable of binding H^+ and Ca^{2+} (I); second, positively charged groups (at a density of σ_2) at $pH \leqslant 7$ and uncharged at $pH > 7$ (II); third, negatively charged groups not capable of binding ions within a studied range of H^+ and Ca^{2+} concentration (III). The groups of type III were assumed to obtain a better quantitative agreement between experimental and theoretical relationships.

Because in our case, in solution, the concentration of univalent ions is large compared with that of divalent ions, the following relationship holds

$$\sqrt{\frac{DkT}{2\pi}}\, C_0 \cdot 2 \sin h \frac{e\psi_0}{2kT} = \sigma_B + \sigma_{ad}$$

where D is the dielectric constant of water; e, the electronic charge; k, the Boltzmann constant; T, absolute temperature; C_0 represents the total concentration of univalent ions (cations or anions) in solution per cm^3; σ_B is the charge tightly bound to membrane in our experimental conditions (with $pH < 7$, $\sigma_B = -\sigma_1 + \sigma_2 - \sigma_3$; with $pH > 7$, $\sigma_B = -\sigma_1 - \sigma_3$); σ_{ad} is the charge of the bound cations calculated according to the Langmuir formula in combination with the Boltzmann distribution law.

The shape of the ψ_0–pH and ψ_0–ionic strength curves is determined from the densities σ_1, σ_2, σ_3, the adsorption constant for Ca^{2+} (K_{Ca}) and the concentration of calcium. The adsorption constant for H^+ for the groups types I and II shifts the curves along the pH axis, and does not affect their shape. The numerical values of the parameters σ_1, σ_2, σ_3 and K_{Ca}, chosen so as to fit theoretical curves to the whole set of experimental data, are as follows: $\sigma_1 = 3{\cdot}3 \times 10^{13}$ cm^{-2}; $\sigma_2 = 2{\cdot}8 \times 10^{13}$ cm^{-2}; $\sigma_3 = 1{\cdot}9 \times 10^{13}$ cm^{-2}; $K_{Ca} = 5$ m^{-1} ($pK_{Ca} = 0{\cdot}7$). It should be emphasized that small variations of σ_1, σ_2, σ_3 and K_{Ca} from these numerical values result in marked discrepancies between ψ_0 and $V_{1/2}$.

Figs. 2 and 3 illustrate the curves obtained from the above equation with the parameters given, the values of pK_H for the groups of types I and II being 4·5 and 9·25 respectively.

A good fit of ψ_0 to $V_{1/2}$ with the same values of $\sigma_1, \sigma_2, \sigma_3$ and the same pK_{Ca}, when necessary, was observed for Ni^{2+}, Co^{2+} and Mg^{2+} with $pK_{Ni} = 1{\cdot}0$; $pK_{Ca} = 0{\cdot}9$; $pK_{Mg} = 0{\cdot}5$. It is implied that these divalent ions are bound by the groups of type I. As an example, Fig. 4 illustrates the effect of Ni^{2+} on $V_{1/2}$ (left hand ordinate) and ψ_0 (right hand ordinate) with and without Ca^{2+}.

From biochemical evidence the groups of type I, with $pK_H = 4{\cdot}5$ and pK values for divalent ions as indicated, are most likely to be carboxyl groups whereas the groups of type II, with $pK_H = 9{\cdot}25$, would be amino groups. The groups of type III might be carboxyl as well, but

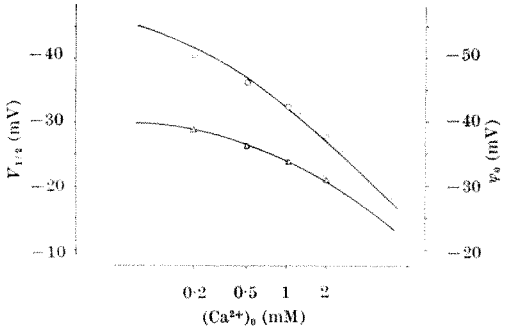

Fig. 3. Changes in $V_{1/2}$ and ψ_0 with calcium in normal (△) and 2·5 fold reduced ionic strength (○). Symbols represent the mean values, with respect to four experiments, for $V_{1/2}$. For the ψ_0–Ca^{2+} curve, see text. $K^+ = 50$ mM.

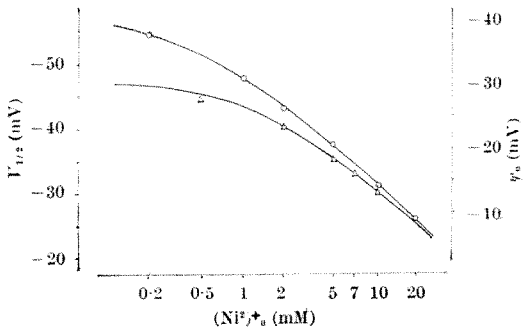

Fig. 4. Changes in $V_{1/2}$ and ψ_0 with Ni^{2+} concentration. △, In 2 mM Ca^{2+}; ○, no Ca^{2+}. Symbols represent the mean values, with respect to four fibres, for $V_{1/2}$. $K^+ = 100$ mM.

because of closely spaced positive charges, these groups have pK_H and pK_{Ca} values a unit or two lower and do not therefore participate in cation binding.

Thus the net surface charge is the sum of charges of the groups of all three types ($-\sigma_1 + \sigma_2 - \sigma_3 = -2{\cdot}4 \times 10^{13}$ electronic charges cm^{-2}) plus the charge of ions adsorbed (at pH 7 and 2 mM Ca^{2+} this charge is $+0{\cdot}7 \times 10^{13}$ electronic charges cm^{-2}) giving $-1{\cdot}7 \times 10^{13}$ electronic charges cm^{-2} in normal conditions.

Thus we may say that experimental shifts of $V_{1/2}$ and calculated changes in ψ_0 prove to be in good quantitative agreement, so that the shifts in the G_m–V_m curves produced by various factors may be actually presented as changes in membrane surface potential.

It may be helpful to correlate experimental evidence and theoretical curves. It must be emphasized, however, that by extending various experimental conditions involving shifts of $V_{1/2}$, and thus minimizing the arbitrariness in our choice of the parameters involved in the formulae for ψ_0, we substantially increase the value of this information. Thus for a quantitative agreement between ψ_0 and $V_{1/2}$ which is affected only by calcium and not by other factors[3,4], it is sufficient to assess the number of calcium binding sites as no less than 2×10^{13} cm^{-2} and pK values as no more than 1·5, the charge of each group being arbitrary. When $V_{1/2}$ is affected by several factors simultaneously, the calculation of all the curves is possible only with assumptions of the density of calcium binding sites, the charges on the sites and K_{Ca}. In this way we calculated σ_1 and pK_{Ca} as $-3{\cdot}3 \times 10^{13}$ cm^{-2} and 0·7 respectively.

The results presented may be useful for understanding the conductance–voltage relationships. Thus we may think that Ca^{2+}, or other divalent ions, are not essential in membrane conductance changes resulting from membrane potential changes, because the basic effect of calcium concentrations (namely, the shift of G_m–V_m curves along the voltage axis) is fully explained by changes in ψ_0. The surface membrane charge, resulting in ψ_0, should therefore be taken into account in any hypotheses concerning the mechanism of ionic conductance in excitable membrane.

Initial Characterization of a Temperature Sensitive Mutant of Monkey Kidney Cell

AMONG the several temperature sensitive conditional mutants of the tetraploid cell line of African green monkey kidney (BS-C-1) is one (*ts*-2) in which simian virus 40 either fails to multiply or form tumour specific antigens (unpublished) at the temperature (39·5° C) at which cellular growth is restricted[1]. Because of the potential importance of this mutant in the study of host dependence of tumour virus multiplication, we have investigated several of its properties and have found that the mutant *ts*-2 is blocked in the incorporation of ^{3}H-thymidine in the nucleus, probably in the nucleolus.

The wild type parental cell line of BS-C-1 and the temperature sensitive mutant *ts*-2 passage 5 (clonal selection) were grown at 33° C for 3 to 4 weeks in L-15 medium[2] with 10 per cent foetal calf serum. After trypsinization, the cells (about 5×10^5/ml.) were plated in 60 mm plastic Petri dishes containing coverslips[3], at a dilution of 500 cells per plate. Replicate culture places were incubated at 33° C (pm$^+$) and 39·5 °C (pm$^-$). Every 24 h two plates from each set were taken out, the existing medium changed for fresh L-15 medium, each with 30 μCi/ml. ^{3}H-thymidine (^{3}H-TD) and 25 μCi/ml. of ^{3}H-uridine (^{3}H-UD), and the plates incubated for a further period of 4 h at the respective temperatures. [*methyl*-^{4}H]-Thymidine and generally labelled ^{3}H-uridine were obtained from the Radiochemical Centre, Amersham. Coverslips taken from culture dishes were washed in phosphate buffered saline (PBS) at *p*H 7·4, fixed in glacial acetic acid : ethanol (1 : 3), washed with 10 per cent trichloroacetic acid (TCA) and rinsed in methanol. Dried coverslips were counted directly in toluene-based scintillation fluid (efficiency 35–40 per cent) for total incorporation[4–6] of ^{3}H-TD and ^{3}H-UD in comparable conditions between the two cell lines at the pm$^+$ and pm$^-$ temperatures.

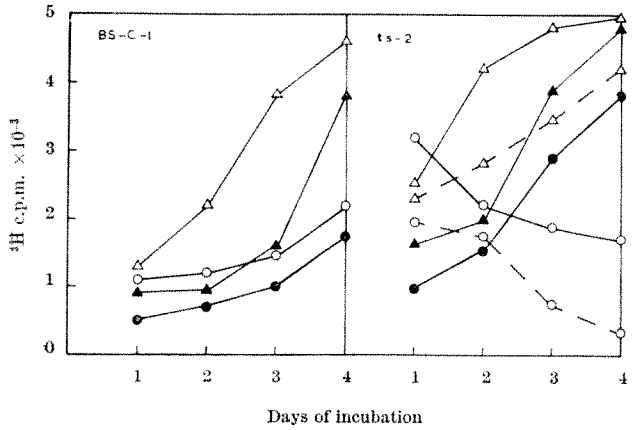

Fig. 1. Total incorporation of ^{3}H-TD (○,●) and ^{3}H-UD (△,▲) by African green monkey kidney cell line BS-C-1 and a temperature sensitive mutant clone *ts*-2, passage 5, incubated at the temperatures of 33° C (●,▲), and 39·5° C (○,△) at a cell density of approximately 5×10^5/ml. Replicate cultures were exposed every 24 h for a period of 4 h to ^{3}H-TD (30 μCi/ml.) and ^{3}H-UD (25 μCi/ml.) at respective temperatures. Discontinuous lines in the graph refer to results of experiments performed with passage 3 of the mutant clone *ts*-2. Details in text.

Results (Fig. 1) showed that during the first 4 days of incubation, the mutant *ts*-2 grew better than the parent (BS-C-1) at the pm$^+$ temperature, as indicated by higher incorporation of both ^{3}H-TD and ^{2}H-UD. In the pm$^-$ temperature, on the other hand, the BS-C-1 cell line had grown distinctly better than at 33° C, whereas the temperature sensitive mutant *ts*-2 showed relatively little increase in the incorporation of ^{3}H-TD at 39·5° C over this period. The mutant *ts*-2, however, showed at least two to three-fold more thymidine incorporation on the first day at 39·5° C than at 33° C and this gradually decreased over the next 3 days. For the corresponding period incorporation of ^{3}H-UD by the mutant *ts*-2 had remained unaffected as compared with the parent cell line (BS-C-1). The increase in the incorporation of ^{3}H-TD by the mutant *ts*-2 at the pm$^-$ temperature of 39·5° C might be attributed to the enlarging of the cell[1], caused by some unscheduled activity in the cytoplasm under conditions of absence or reduction of nuclear DNA synthesis. This is also corroborated by the results of autoradiography (Figs. 3 and 4). It should be noted (Fig. 1) that ^{3}H-TD and ^{3}H-UD incorporation by the mutant *ts*-2 at 39·5° C at an earlier passage (passage 3), though showing lower incorporation of both thymidine and uridine, also exhibited a similar trend in gradual decrease in thymidine incorporation. The difference in the rate of incorporation of ^{3}H-TD by the mutant *ts*-2 at 39·5° C between successive passages could only be attributed to leakiness of the mutant itself. It has been noted that this particular mutant (*ts*-2) showed increased leakiness with every passage, and beyond the twelfth passage it reverted considerably in its growth and metabolic activity, and was comparable with the parent BS-C-1 cell line between 33° C and 39·5° C.

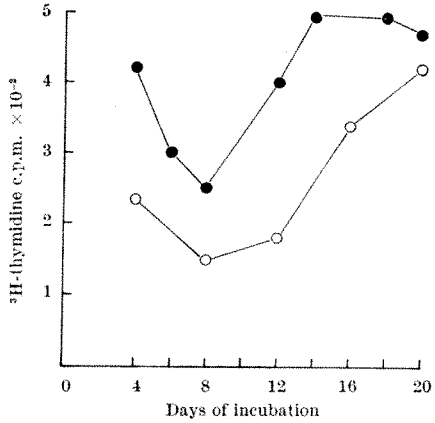

Fig. 2. Total incorporation of ^{3}H-TD by the temperature sensitive mutant clone *ts*-2, passage 5, grown at 39·5° C, shifted to 33° C for 4 h (●) following exposure to ^{3}H-TD (10 μCi/ml.). Replicate cultures used as controls (○) of *ts*-2 were exposed to ^{3}H-TD and incubated at 39·5° C for an equal length of time. Details in text.

To determine the inability of cells exposed to restrictive temperature for 20 days a temperature-shift experiment was done (Fig. 2). Replicate culture plates of the mutant cell line *ts*-2 passage 5 were incubated in conditions identical to those mentioned here, at the restrictive temperature of 39·5° C. Every 48 h culture plates were exposed to ^{3}H-thymidine (10 μCi/ml.) and incubated at the permissive temperature of 33° C for another 4 h. Replicates used as controls were incubated at 39·5° C. At least some cells remained viable for 20 days and continued to incorporate ^{3}H-TD when transferred to 33° C, though at a relatively lower rate. It should be noted that for the first 8 days the rate of ^{3}H-TD incorporation slowly decreased. This could indicate that the nature of the mutation had remained dominant in the initial stages of growth at 39·5° C, but, probably due to leakiness, the rate of ^{3}H-TD incorporation increased slightly from the eighth day onwards.

BS-C-1 and *ts*-2 (passage 5) cell lines grown at 33° C for 3–4 weeks were trypsinized, seeded overnight on coverslips in Petri dishes at 33° and 39·5° C and then exposed to 30 μCi/ml. of ^{3}H-thymidine for 48 h at the respective temperatures. Cells were then washed twice in PBS, fixed in acetic acid–ethanol (1 : 3) and the coverslips dried at room temperature. The latter were dipped

in Ilford 'L-4' liquid emulsion fluid in 1 per cent No. 1 gelatine solution and kept in the cold for 7 days before being processed. Control coverslips were run simultaneously to determine any background effect or artefacts.

The mutant *ts*-2 (clonal passage 5), although showing normal incorporation of thymidine at the pm$^+$ temperature of 33° C (Fig. 3*B*), had very little thymidine incorporation in the nucleus (and, probably, the nucleolus) at the pm$^-$ temperature of 39·5° C (Fig. 3*C*). When compared with the parent cell line BS-C-1 (Fig. 4*A*) at 39·5° C, the mutant (Fig. 4*B*) was uniformly labelled in the cytoplasm and/or nuclear membrane. A long pulse of 48 h of ^{3}H-TD was given to make sure that the reduced activity in the mutant cell line at higher temperature was not due to a low level of metabolic activity. This did not make it clear whether the incorporated thymidine was in fact in the cytoplasmic DNA or had been demethylated into uridine. Whatever the degradative product of thymidine incorporation, the temperature sensitive mutant (*ts*-2) was relatively inactive in the nucleus or nucleolus at the restrictive temperature of 39·5° C. The temperature sensitivity of *ts*-2 was probably due, therefore, to a mutation involving the nucleus.

Monolayer cell cultures of both BS-C-1 and *ts*-2 (passage 5) were grown in 20 ounce bottles for 3–4 weeks in L-15 medium at the permissive temperature of 33° C. Cells were then trypsinized and seeded at a density of 5×10^7/ml. in glass bottles and replicates incubated overnight at 33° and 39·5° C. After 24 h the culture medium was exchanged for fresh L-15 medium with 30 μCi/ml. of ^{3}H-thymidine and incubated 48 h more at the respective temperatures.

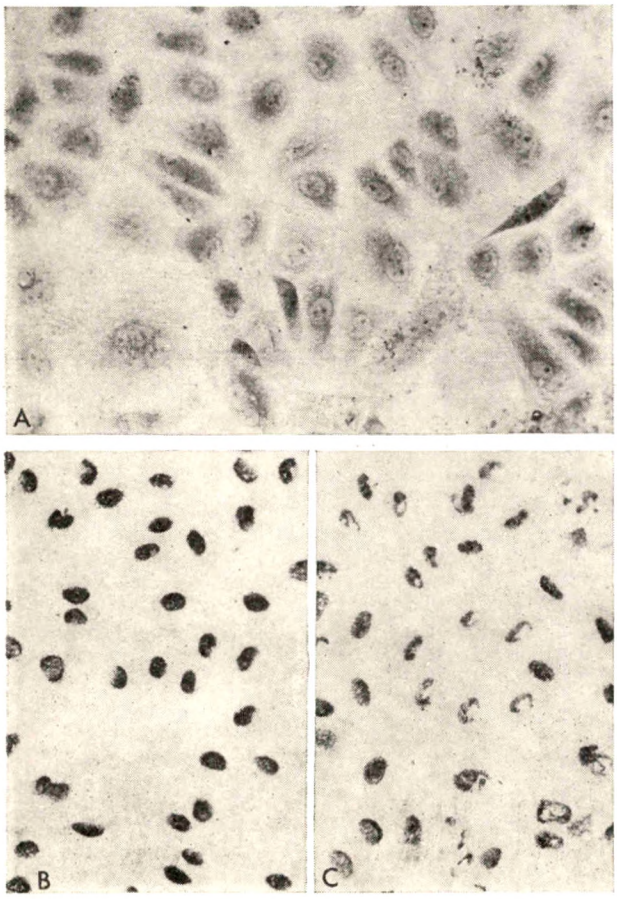

Fig. 3. *A* shows a confluent monolayer of mutant clone *ts*-2 grown at the pm$^+$ temperature of 33° C for 7 days and stained in pyronin methyl green (×180). *B* and *C* show autoradiographs (×120) of the mutant *ts*-2 at 33° C and 39·5° C respectively after exposure to ^{3}H-TD (30 μCi/ml.) for 48 h.

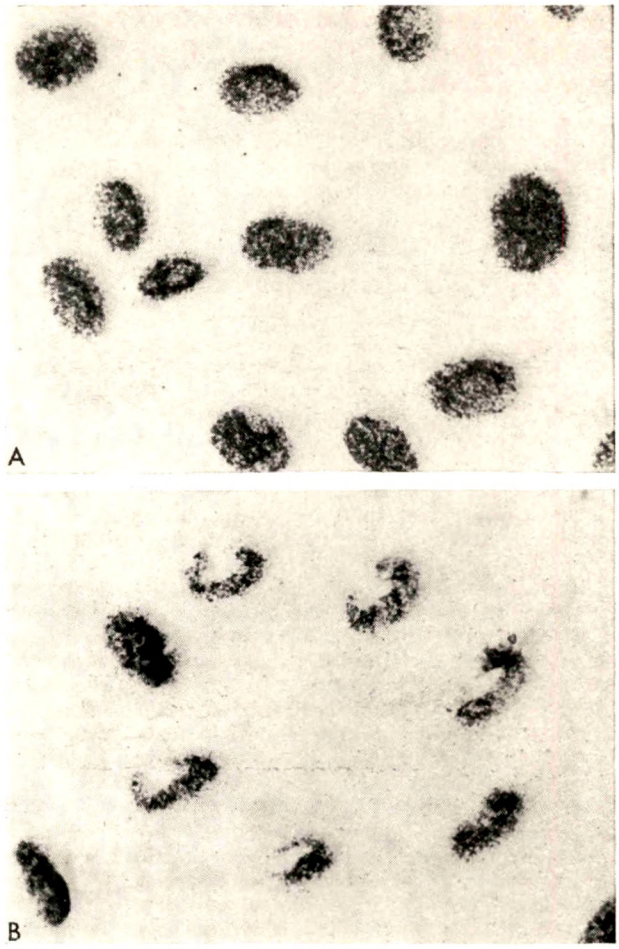

Fig. 4. Autoradiographic pictures (×288) of BS-C-1 (*A*) and the mutant *ts*-2 (*B*) grown at 39·5° C after exposure to ^{3}H-TD (30 μCi/ml.) for 48 h.

Cells were then washed twice with PBS, trypsinized and collected in PBS, centrifuged and washed twice in calcium and magnesium-free PBS buffer at 1,000 r.p.m. for 10 min. The centrifugate was resuspended in 2 ml. of Ca-Mg-free PBS (cell density $2·5 \times 10^8$/ml.) and layered over 10 ml. of 0·3 M sucrose and centrifuged at 1,000 r.p.m. for 20 min. The pellet containing whole cells was finally resuspended in 4·5 ml. of 0·3 M sucrose, disrupted by the Ultra-Turrax disintegrator[7] until 90 per cent cells were disrupted (observed under the microscope). 0·05 ml. of 10 mM magnesium acetate and 0·5 ml. of 100 mM KCl were added. Cellular fractions[7,8] of labelled nuclei, mitochondria, microsomes and cell sap were separated and the specific activity of the TCA insoluble protein in each fraction determined[9] using the method of Lowry *et al.*[10].

Fractions of cellular organelles were collected as follows. The homogenates were centrifuged for 30 min at 2,000 r.p.m. in the horizontal rotor to sediment the nuclei. The supernatant fluid was used for the isolation of mitochondria and microsomes. The nuclear pellet was further purified by washing twice in 0·3 M sucrose containing 1 mM $MgCl_2$ and 0·5 per cent (w/v) 'Triton X-100' and twice with 0·15 M NaCl. The supernatant fluid remaining after the sedimentation of the nuclei was centrifuged for 10 min at 10,000 r.p.m. in the Sorvall SS-34 rotor to sediment the mitochondria. The pellet was resuspended in 0·3 M sucrose and resedimented for 15 min at the same speed. The last two supernatant fluids remaining after sedimentation of the mitochondria were centrifuged for 1 h at 50,000 r.p.m. in the MSE-50 rotor (10×10 ml.) to sediment the microsomal fraction; the

supernatant contained the cell sap. The pellet was resuspended in 0·3 M sucrose and centrifuged for 10 min at 10,000 r.p.m. in the Sorvall to sediment the small amount of mitochondrial material carried over in the previous steps. The supernatant fluid was then diluted with an equal volume of 0·15 M NaCl and the mixture centrifuged at 50,000 r.p.m. for 1 h. All steps in the cellular fractionation were carried out at 0°–2° C.

Table 1. LEVELS OF INCORPORATION OF ^{3}H-TD IN DIFFERENT CELLULAR FRACTIONS OF BS-C-1 AND *ts*-2 CELL LINES AFTER 48 HOURS EXPOSURE TO ^{3}H-TD AT 39·5° C, CALCULATED IN RESPECT OF RADIOACTIVITY IN TOTAL COLD TCA PRECIPITABLE PROTEIN

	c.p.m./mg protein ($\times 10^{-3}$)	
	BS-C-1	*ts*-2
Nuclei	310·0	78·6
Mitochondria	10·4	4·8
Microsomes	5·1	50·2
Cell sap	3·6	4·2

The results (Table 1) showed a remarkably high radioactivity per mg of protein in the microsomal fraction of the cytoplasm in the mutant *ts*-2 when compared with the identical fraction of the parental cell line BS-C-1. The nuclei of *ts*-2, on the other hand, had relatively little radioactivity as compared with the BS-C-1 cell line. This is consistent with the autoradiographic data. The low level of incorporated ^{3}H-TD in the mitochondrial fraction of the mutant cell line *ts*-2 at 39·5° C was thought to be significant. The number of c.p.m. per mg of protein were reduced by nearly a factor of four in the nuclei of the mutant when compared with the parental cell line, and that of mitochondria had decreased by nearly a factor of two, which in the mutant was similar to the amount of radioactivity in the cell sap (mitochondria : cell sap = 4·8 : 4·2). It is difficult to say from these data that the low level of 3H-TD incorporation by the mitochondria of mutant cell line *ts*-2 at the pm$^-$ temperature (39·5° C) is a direct effect of the inactivity of the nucleus. Further experiments are in progress to determine the exact nature of thymidine metabolism in the cytoplasm of the mutant cell line *ts*-2. It might be mentioned in this connexion that there have been several recent reports[8,11,12] of DNA associated with the microsomal fraction of mammalian cells which closely resembles nuclear DNA but is more rapidly labelled with isotopic precursors.

We tentatively conclude that the mutant cell line *ts*-2 was probably defective in the nucleic acid metabolism in the nucleus or in the nucleolus at the pm$^-$ temperature. The mutant, however, was visibly normal in growth at the pm$^-$ temperature of 33° C (Fig. 3*A*). The parental cell line BS-C-1 had remained unaffected between these two temperatures. The metabolic end product of the incorporated 3H-TD in the cytoplasm of the mutant at the restrictive temperature was not studied during these experiments. Long exposures to ^{3}H-TD indicated that a small percentage of the [methyl-^{3}H] thymidine had been demethylated into uridine. This part of the work is now being carefully investigated.

Differences in Rh Type between Age Groups of Leukaemia Patients

IN view of the variation of the incidence of leukaemia in relation to age, sex and chronicity[1], I have investigated the ABO and Rh blood groups in subsamples of these categories. Significantly I found higher Rh negative frequencies among patients between groups 0–4 years old and more than 50 years old compared with those between 5 and 50.

The medical record numbers of all patients with a diagnosis of leukaemia were obtained from the Columbia–Presbyterian Medical Center, New York City, for the period 1945 to 1958; the data were collected in 1959. All information was taken from the medical record of each patient. The diagnosis of leukaemia was based on laboratory reports on bone marrow, blood and lymph node biopsy specimens, X-ray findings (children) and autopsy reports. Usually more than one of these sources of information was available for a given patient. There were 581 Caucasian patients—458 Gentiles and 123 Jews. Only the analysis of the Gentile sample was undertaken because the very limited size of the Jewish sample precluded meaningful analysis.

Because it is known that leukaemia is most frequent before 5 and after 50 yr (ref. 2), the study population was divided into three age groups: 0–4, 5–50 and more than 50 yr.

Table 1. DISTRIBUTION OF ABO AND Rh BLOOD GROUPS IN ACUTE AND CHRONIC LEUKAEMIA PATIENTS AND AGE AT DIAGNOSIS

Age at diagnosis	Chronicity	Rh type	ABO blood groups O	A	B	AB	Total	Per cent Rh
0–4	Acute	Positive	17	26	7	3	53	77·94
		Negative	5	7	2	1	15	22·06
	Chronic	Positive	3	3	0	0	6	66·67
		Negative	2	1	0	0	3	33·33
5–50	Acute	Positive	46	41	12	3	102	88·70
		Negative	8	4	1	0	13	11·30
	Chronic	Positive	11	19	3	1	34	89·47
		Negative	2	1	1	0	4	10·53
51–90	Acute	Positive	17	15	7	1	40	74·07
		Negative	6	8	0	0	14	25·93
	Chronic	Positive	32	27	9	3	71	78·89
		Negative	4	11	4	0	19	21·11

Blood group determinations were available for 374 Gentile patients, and the proportions of each sex within a given age group were comparable ($P > 0·15$ in each case). There is no suggestion of differences in the distribution of the ABO blood groups between categories of age or chronicity (Table 1), although a much larger sample is clearly required to give meaningful results. The Rh frequencies are remarkably similar between acute and chronic leukaemia patients within each age group, but the distribution of these frequencies among the three age groups differs significantly, $\chi^2 = 8·71$, 2 d.f., $P < 0·15$ (Table 2).

Table 2. DISTRIBUTION OF Rh TYPE IN RELATION TO SEX AND AGE OF PATIENT

Age groups	Rh type	Male *n*	Male Per cent	Female *n*	Female Per cent	Male and female *n*	Male and female Per cent	Total *n*
0–4	Positive	30	73·17	29	80·56	59	76·62	77
	Negative	11	26·83	7	19·44	18	23·38	
5–50	Positive	81	93·10	55	83·33	136	88·89	153
	Negative	6	6·90	11	16·67	17	11·11	
51–90	Positive	71	79·78	40	72·73	111	77·08	144
	Negative	18	20·22	15	27·27	33	22·92	
Total	Positive	182	83·87	124	78·98	306	81·82	374
	Negative	35	16·13	33	21·02	68	18·18	

When the data for males and females are analysed separately, the heterogeneity in the Rh frequencies among the age groups in males is statistically significant, but although the same trend prevails in females, it is not significant. None of the comparisons between males and females differs significantly.

Independent comparisons of age groups 0–4 and 51–90 yr with 5–50 yr indicate a significant excess of Rh negative patients in each of the two former groups in males, and in the combined data of males and females, $P < 0.02$ or less. Thus the increased Rh negative frequency is observed in the two age groups associated with a high incidence of leukaemia.

No factors seem to favour the admission of leukaemia patients to the hospital from which my sample was obtained on the basis of Rh type and age. Since for most patients the diagnosis was established at this hospital, it is not likely that blood groups were determined in relation to their disease before admission. Decreased agglutinability of the D (Rh) antigen, or two populations of cells (Rh positive and Rh negative), have been reported in very small samples of patients with leukaemia[3,4]. This evidence, however, does not warrant the assumption that "complete" loss of agglutinability of the D antigen can explain the excess of Rh negative patients in the age groups observed in this study. Furthermore, there is evidence of immunological similarities between certain autoimmune diseases and some leukaemic states[5], and that the thymus is involved in idiopathic autoimmune diseases and in malignant proliferation, such as leukaemia[6]. Thus it may not be fortuitous that an excess of Rh negative[5] was found in patients with autoimmune diseases[7], and, in this report, among patients in the age groups associated with the highest susceptibility to leukaemia.

I thank Professor James F. Crow for his help and Dr John S. Grove for statistical advice. This work was carried out in the Department of Medicine, College of Physicians and Surgeons, Columbia University, New York, and supported by the Commonwealth Fund.

Effects of Anti-lymphocyte Serum on Uptake of Uridine by Lymph Nodes during Carcinogenesis

ANTI-LYMPHOCYTE serum (ALS) has been shown to influence the course of experimental carcinogenesis, enhancing susceptibility to oncogenic viruses[1,2] and the carcinogenic action of dimethylbenz(α)anthracene (DMBA)(ref. 3). Subcutaneous administration of ALS augmented the production of tumours formed in hamster cheek pouches by topical applications of DMBA and details of tumour incidence have been reported[3]; 95 per cent of pouches contained tumours after 12 weeks, compared with 70 per cent in untreated animals.

In vitro studies have demonstrated that lymphoid blast cells incorporate more RNA precursor than other cells of the lymphatic population[4]. We wish to describe here some general aspects of regional lymphatic involvement during carcinogenesis in an immunologically privileged site, and an assay of lymphoid blast cells exhibiting RNA synthesis, possibly concerned in the elaboration of a cell mediated response to an antigen. The cheek pouches of twenty-eight conventionally bred and maintained golden Syrian hamsters (*Mesocricetus auratus*) were painted three times a week with 0·5 per cent DMBA in mineral oil (Sigma). Sixteen of these animals received ALS, which had been prepared in rabbits, had a cytotoxic titre greater than 256 as determined by the trypan blue exclusion test, and was administered according to a regimen described earlier[3]. Comparisons were made with ten untreated hamsters and seven animals whose cheek pouches were painted with butylated hydroxyanisole (BHA) for 15 weeks. The latter were a by-product of experiments to test the carcinogenic potential of hydroxyanisoles, chemicals known to cause chronic inflammation and structural changes in the hamster cheek pouch, comparable with the early effects of DMBA (ref. 5).

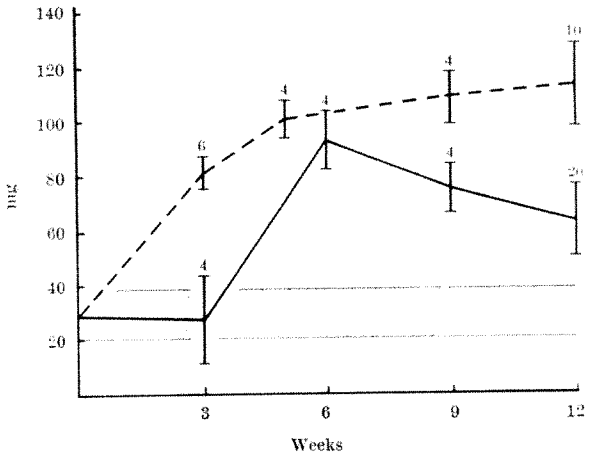

Fig. 1. Weights of submandibular lymph nodes; untreated hamsters (hatched area), treated with DMBA (- - -), treated with ALS/DMBA (———). Numbers of lymph nodes weighed are indicated.

When treatment commenced the animals were 4–6 weeks old and weighed on average 85 g. The BHA group was killed after 15 weeks; others were killed at intervals. Sub-mandibular lymph nodes were removed, stripped of extraneous tissue and weighed.

For autoradiography, two animals were taken at each of the following states: (i) without treatment; (ii) after 15 weeks of BHA; (iii) after 3 weeks of DMBA; (iv) after 3 weeks of ALS/DMBA; (v) after 12 weeks of DMBA; (vi) after 12 weeks of ALS/DMBA. Hamsters in groups (v) and (vi) carried one or more tumours in each pouch. Ninety minutes before being killed, each received intraperitoneally 10 μCi/g of 5-^{3}H-uridine (specific activity 5·0 Ci/mole; Radiochemical Centre, Amersham). Material for light microscopy was fixed in buffered formol saline and processed using Ilford K5 dipping emulsion. Tissue for electron microscopy (EM) was fixed in phosphate buffered 2 per cent osmium tetroxide and exposed with Ilford L4 emulsion. Most light autoradiographs were stained with haematoxylin and eosin but some were prepared with methyl green and pyronin. Cells were counted on six or more light autoradiographs of each node, examining twenty-four random areas of the node core at a magnification of × 800.

At the beginning of the experiment the lymph nodes were considered to be fully developed[6]. Their weights were recorded (Fig. 1) throughout the experiment and it was found that DMBA treatment caused increasing hypertrophy of the lymph nodes. ALS partially suppressed this enlargement.

In the light autoradiographs, the paracortical regions of all nodes examined contained large, pyroninophilic

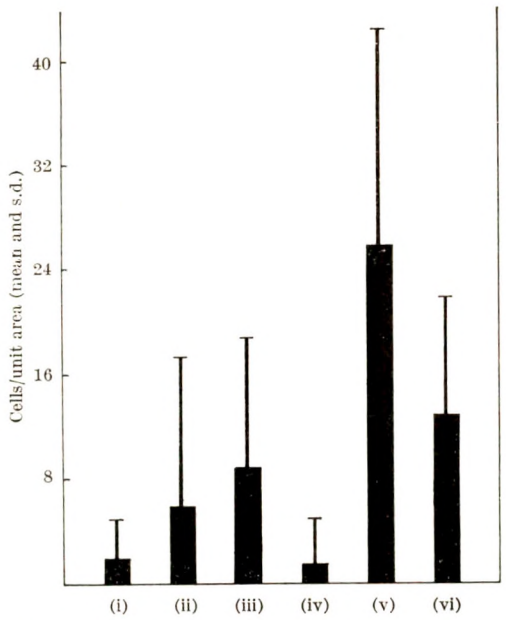

Fig. 2. Numbers of large, pyroninophilic, labelled cells counted/unit area in light autoradiographs. (i) Untreated; (ii) BHA 15 weeks; (iii) DMBA, 3 weeks; (iv) ALS/DMBA, 3 weeks; (v) DMBA, 12 weeks; (vi) ALS/DMBA, 12 weeks.

cells, some of which were labelled with uridine; their relative numbers are presented in Fig. 2. In electron microscope autoradiographs (Fig. 3) the labelled cells resembled lymphoblasts. They had a maximum diameter of 24 μm, their cytoplasm contained abundant polysomes and their nuclear chromatin was almost totally in the expanded form. They were surrounded by unlabelled small lymphocytes; medullary plasma cells with dilated endoplasmic cisternae, neutrophils, eosinophils and some blast-like cells were unlabelled.

The degree of lymph node hypertrophy was paralleled by the relative number of RNA synthesizing blast cells. The strongest reaction was evoked in the animals treated with DMBA which bore pouch tumours but whether this large number of active blast cells could be attributed to the cumulative effects of DMBA or to the presence o tumour antigens was not ascertained. Lymphoid hyper trophy and blast cell formation have been observed i mice receiving chronic ALS treatment[7] and, althoug similar hyperactivity was evident in the lymph nodes o the hamsters treated with ALS and DMBA, their respons was poor when compared with those on DMBA alone.

Lymphatic connexion between the hamster chee pouch and the submandibular lymph node can be demon strated by tracing with Evans blue (unpublished work c C. J. Smith), and therefore it is not surprising that a antigenic stimulus in the pouch, although the latter i immunologically privileged, may affect the regional node Treatment with ALS can influence the incidence an generation time of chemically induced cheek pouc carcinomas[3] and also partially suppresses regional lym phoid activity, which suggests that ALS interferes wit efferent and/or afferent cell traffic between the pouc and the regional node.

Impairment of the cell mediated immune response an blast cell activity by ALS, as evidenced by the relativ numbers of cells able to take up large quantities of uridine may be related to the enhancement of pouch tumours.

We thank D. F. Tucker, R. H. Raymond and Miss Su Northfield for advice and assistance.

Morphological Confirmation of the Herpes Nature of a Carcinogenic Virus of Primates (*Herpes saimiri*)

Interest in the possible relation of herpes viruses t cancer has been aroused by the discovery of the herpes like EB virus in cultured Burkitt tumour cells[1,2]. Th association of EB virus with malignant change has subse quently been strengthened by sero-epidemiological studie on patients with Burkitt's lymphoma[3,4], by observation on the effects of the virus when it infects and stimulate human lymphoid cells *in vitro*[5–7], and by its incriminatio as the aetiological agent of the limited *in vivo* lymph proliferation of infectious mononucleosis[8–10].

The importance of these findings has been confirme by new developments showing herpes viruses to b carcinogenic in animals. A herpes virus long known t occur in cells of the Lucké frog kidney carcinoma[11] ha been shown to cause malignant kidney tumours whe injected into frog embryos[12], and this carcinogenic fro agent shares a common antigen with EB virus[13]. I addition, a virus has at long last been isolated fro Marek's chicken lymphoma[14,15], has been identified as th causative agent[16,17], and has likewise been shown to be typical herpes virus[18,19].

Figs. 1–6. Electron micrographs of material from owl monkey kidney cultures infected with *Herpes saimiri*. Figs. 1 and 2 show thin sections which have been stained with uranyl acetate; Figs. 3 to 6 show whole-mount preparations in PTA. Fig. 1, part of a nucleus containing profuse, hexagonal, immature virus particles, either empty or with dense central (arrows) or ring-shaped nucleoids. (×35,825.) Fig. 2, mature particle with its additional outer enveloping membrane lying within a cellular space bounded by a fine membrane. (×125,000.) Fig. 3, empty hexagonal immature particle which has been penetrated by PTA. The structure of the hollow tubular surface capsomeres is seen well in side view. (×150,000.) Fig. 4, hexagonal immature particle; a central ring-shaped nucleoid is revealed following penetration by PTA. (×150,000.) Fig. 5, undamaged, complete, hexagonal immature particle with hollow capsomeres in end on view arranged in triangular facets. (×150,000.) Fig. 6, mature particle with damaged outer enveloping membrane; PTA has entered to reveal the hexagonal immature component within. (×150,000.)

More recently, a new virus has been propagated in tissue culture from normal squirrel monkey kidney cells[20], and, although without pathogenic effects on its natural host, it regularly induces fatal lympho-reticular tumours on inoculation into owl monkeys and marmosets[21]. The agent is thought to be a herpes virus on the basis of its biological properties, and has been designated *Herpes saimiri*[20], and we now provide definitive morphological confirmation that this squirrel monkey virus is indeed a member of the herpes family.

Confluent owl monkey kidney cell cultures were infected with sufficient virus to give moderate widespread cytopathic change after incubation at 37° C for 12 days. The infected cells were then gently scraped from the glass into suspension in 1 ml. of culture fluid. Thereafter, the cells were either fixed in glutaraldehyde followed by osmium, dehydrated and embedded in epoxy resin for thin sectioning as already described[22], or made into whole-mount negative-contrast preparations in phosphotungstic acid (PTA) by the method of Parsons[23]. Observations were made with a Philips EM 300 electron microscope.

On examination all the infected cultures contained profuse virus particles of herpes-type morphology (Figs. 1 to 6) which were absent in uninoculated control cultures. In thin sections immature hexagonal particles, either empty or with central ring-shaped or dense nucleoids and of about 108 nm diameter, were seen in both nuclei (Fig. 1) and cytoplasm. Mature particles with an additional enveloping membrane measured 140 nm across and lay in the perinuclear space, in cytoplasmic spaces (Fig. 2), or close outside the cell surface.

Whole-mount PTA preparations confirmed the size of the particles (Figs. 3 to 6). Empty particles without nucleoids were penetrated by PTA (Fig. 3) as were some with nucleoids (Fig. 4); intact particles were also seen and often showed triangular surface facets (Fig. 5). All the immature particles were covered by hollow tubular capsomeres 12·5 nm long and with a centre-to-centre spacing of 12·5 nm (Figs. 3 to 5). Although the exact number of capsomeres along the edge of a facet could not be accurately determined, the findings suggest that the immature particle is an icosahedron covered by 162 capsomeres. Mature particles appeared structureless except where the outer enveloping membrane was damaged and allowed PTA to enter and reveal the immature component within (Fig. 6).

On morphological grounds, therefore, *Herpes saimiri* has been confirmed as a member of the herpes virus group. Taken in conjunction with the frog kidney tumour herpes virus[6] and the herpes virus of Marek's disease[9], a carcinogenic herpes virus of primates has important implications for the problem of EB virus and human cancer. Our findings reinforce the need to explore fully the role of herpes viruses in the whole field of neoplasia.

Copper in Hepatocyte Lysosomes of the Toad, *Bufo marinus* L.

ALTHOUGH copper is essential for life, excessive concentrations are usually toxic and may lead to pathological changes in various tissues and eventually death. Acute disturbances, sometimes fatal, may occur in sheep and cattle grazing on pastures enriched with copper. Chronic copper toxicity in animals is unknown, although it occurs in human beings as Wilson's disease (hepatolenticular degeneration)[1]. In these patients greatly increased hepatic copper concentrations, approaching 2,000 μg/g dry tissue (normal: 20–45 μg/g)[2] cause degeneration of hepatocytes, necrosis and ultimately cirrhosis[2,3].

Beck, working in Australia, found copper concentrations as high as 1,640 μg/g dry tissue in the livers of the toad, *Bufo marinus* L.[4]. This was by far the highest hepatic copper concentration of eighty-three species studied. The toad's liver is undamaged by this level of copper, so we have compared the intracellular distribution of the metal in the toad with the distribution previously described in patients with Wilson's disease[3] and in newborn human infants whose livers also tolerate large amounts of copper[3,5].

Samples of liver from ten female toads from the Dominican Republic were fixed in neutral formalin and embedded in paraffin. Sections were examined by light microscopy after staining with: haematoxylin and eosin for histological detail; a modification[3] of Timm's silver sulphide procedure[6] for demonstration of heavy metals; rubeanic acid, for identifying copper[3,7]; and Perls's prussian blue technique, for staining iron[8]. Lipofuscin was identified by Schmorl's[8] and the 3,3′ diaminobenzidine (DAB) reactions[9]. To demonstrate lysosomes frozen sections of tissue fixed in formalin were incubated for acid phosphatase activity with β-glycerophosphate as substrate[10] and β-glucuronidase activity with naphthol-AS-Bl glucuronic acid as substrate[11]. Frozen sections were also stained with oil red O (ref. 10) to demonstrate fat. Portions of four livers were cut into small cubes, fixed in 3 per cent glutaraldehyde in 0·1 M cacodylate buffer, *p*H 7·4, osmicated, dehydrated and embedded in Epon. Thin sections were stained with uranium and lead for examination in a Siemens Elmiskop 1*a* electron microscope.

Grossly, these toad livers, like those of other amphibians, were generally black and under the light microscope there were large numbers of cells, probably macrophages[12], filled with melanin granules. Some livers were yellow, however, and in these specimens the hepatocytes contained numerous large lipid droplets, up to 10 μm in diameter. Cytoplasmic fat was seen in the black livers, but the droplets were about a tenth as large and far less numerous. No evidence of necrosis or fibrosis was seen in any of the ten livers.

Fig. 1. Copper demonstrated with rubeanic acid is localized in the pericanalicular pigment granules (arrows) of toad hepatocytes. (×1,800.)

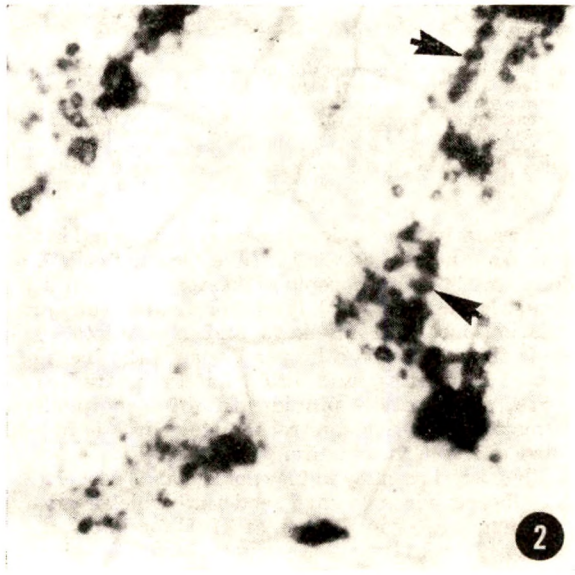

Fig. 2. Many pericanalicular granules (arrows) show the staining characteristic of lipofuscin in a section of toad liver stained with Schmorl's technique. (×2,000.)

In unstained sections numerous brown granules were seen arrayed along the bile canaliculi of hepatocytes and these contained heavy metals demonstrable with the silver sulphide procedure. Staining with both rubeanic acid (Fig. 1) and Perls's prussian blue procedure showed that the metal was copper and not iron. No copper was demonstrated elsewhere in the cell. The granules were Schmorl positive (Fig. 2), and showed heat stable peroxidase activity with DAB and acid phosphatase and β-glucuronidase activities, all characteristic of lysosomes that contain lipofuscin[5,9]. In the electron micrographs they were delimited by a single membrane and contained membranous, vesicular and granular components of varying electron density (Fig. 3).

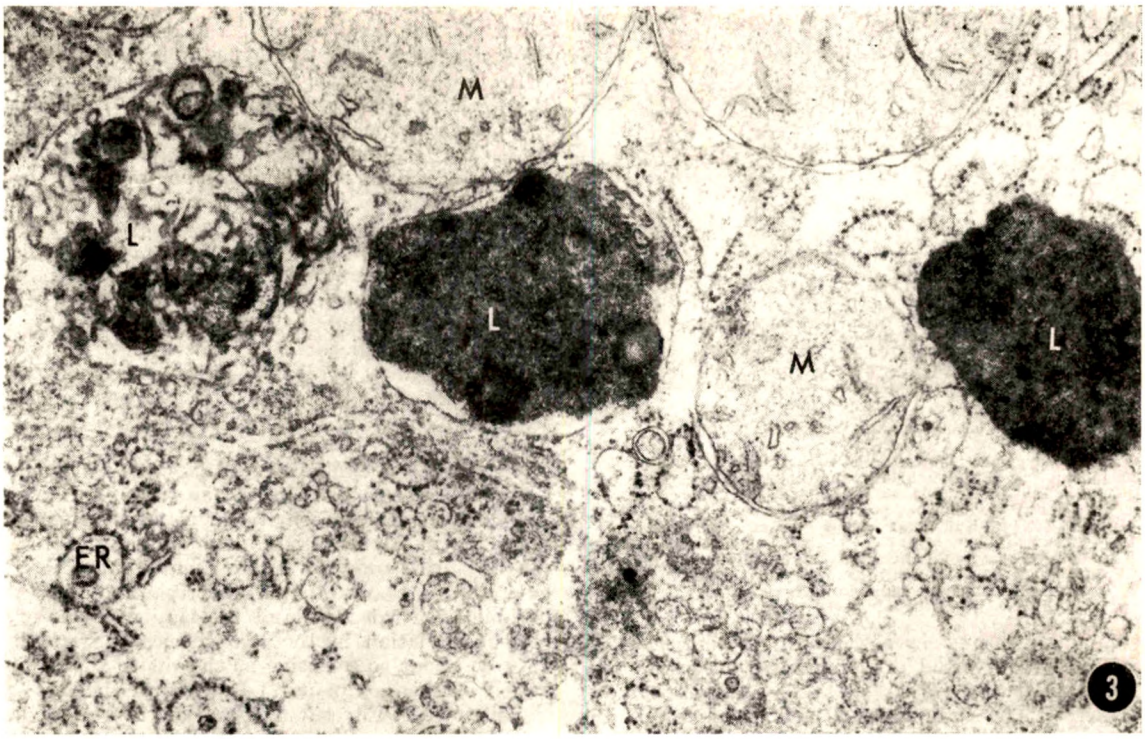

Fig. 3. Electron micrograph showing a portion of a toad hepatocyte with membrane bounded dense bodies or lysosomes (L) the contents of which are similar to those of human lipofuscin granules. Mitochondria (M) and endoplasmic reticulum (ER) are noted. (×20,000.)

Copper concentrations were determined quantitatively[13] on aliquots of liver from six of the toads. The black livers contained about three times as much copper as the fatty, yellow organs (Table 1).

Table 1. HEPATIC COPPER CONCENTRATIONS IN SIX TOADS

Specimen No.	Colour of liver	μg/g dry liver
1	Black	1,265
2	Black	1,248
3	Black	2,091
4	Yellow	367
5	Yellow	559
6	Yellow	459

The localization of these astonishingly high concentrations of copper to lysosomes is identical to our earlier findings in normal human neonates[3,5]. In both toad and baby no pathological effects are associated with these deposits. In contrast, very similar concentrations of copper are diffusely distributed in the cytoplasm of hepatocytes in patients with Wilson's disease and are associated with severe and often fatal pathological changes. Our present findings provide additional evidence of the view that sequestration of copper in lysosomes protects the cell from the toxic effects of the metal[3,14–16].

This work was supported in part by grants from the US Public Health Service and the Life Insurance Medical Research Fund. We thank Dr Richard M. Hays for the toad livers, Miss Edith Korotkin for the quantitative determinations of copper and Miss Marianne Van Hooren for the photomicrographs.

Metabolism of Dimethylnitrosamine by Human Liver Slices *in Vitro*

THE occurrence of carcinogenic nitrosamines in various environmental conditions and the possible hazard to human subjects and animals exposed to them have been discussed in several reviews[1–4]. A wide range of species is susceptible to the carcinogenic action of the nitrosamines but there is no direct evidence for the susceptibility of man. In the absence of such evidence, which could be obtained only by epidemiological studies, an attempt has been made to get indirect evidence by studying the metabolism of dimethylnitrosamine by human liver slices *in vitro* because it seems probable that this compound requires metabolic conversion to form an active carcinogenic intermediate. Dimethylnitrosamine is demethylated in the body to products which are further oxidized to carbon dioxide. One of these products is an alkylating intermediate which methylates cellular com-

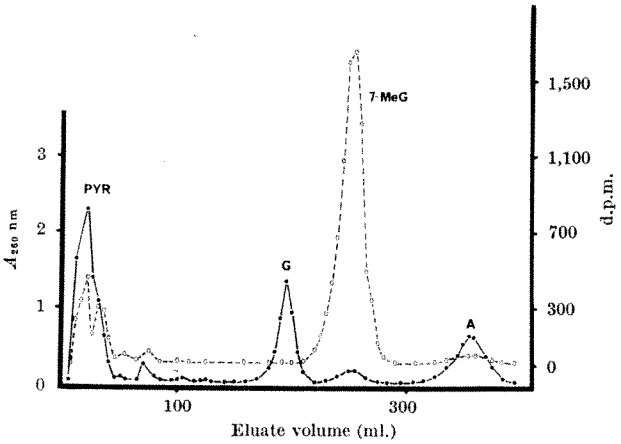

Fig. 1. Ion-exchange chromatography of nucleic acids of human liver slices incubated with [^{14}C]dimethylnitrosamine *in vitro*, conditions of incubation as in Table 1. Nucleic acids (DNA and RNA) were extracted from pooled slices by the Schneider procedure[12], followed by hydrolysis in 1 M HCl at 100° C for 1 h and ion-exchange chromatography on Dowex 50 (×12, H^+ form) with exponential 1–4 M HCl gradient elution, 5 ml. fraction volume. ●, A_{260}; ○, radioactivity; PYR, pyrimidine nucleotides; G, guanine; 7-MeG, 7-methylguanine; A, adenine. Carrier 7-methylguanine was added to the hydrolysate.

ponents including nucleic acids and proteins. DNA and RNA are methylated predominantly on guanine to yield 7-methylguanine, other sites being alkylated considerably less[5]. The significance of nucleic acid alkylation in cellular injury and carcinogenesis by nitrosamines has been discussed[1,6].

In the present experiments, incubation of human liver slices with [^{14}C]dimethylnitrosamine has resulted in the production of labelled carbon dioxide and in methylation of the slice nucleic acids, indicating metabolism of the carcinogen. The results have been compared with those obtained with rat tissue slices. The respiration rate of the rat liver slices (Table 1) was comparable with published data[7,8] and the human liver slices showed a lower rate. The ratio of the mean values of oxygen uptake by rat and human liver was 3·2 which is in good agreement with the report of Booth *et al.*[8].

The rate of oxygen consumption was relatively constant over the period of incubation (100 min) and not influenced by the presence of dimethylnitrosamine, as shown before[7].

Table 1. METABOLISM OF [^{14}C]DIMETHYLNITROSAMINE BY TISSUE SLICES *in vitro*

Tissue	Average weight/flask (mg)	O_2 uptake (μl. O_2/g wet wt/h)	Total radioactivity of $BaCO_3$ (d.p.m.)	$^{14}CO_2$ production (per cent ^{14}C added)
Rat liver	162	760	213,280	5·2
Human liver	162	240	126,100	3·0
Rat kidney	147	2,560	21,680	0·51

Rat tissues were obtained from female Wistar derived albino rats (about 200 g body weight) bred at the Courtauld Institute. Small pieces of human liver weighing approximately 1 g were placed in ice-cold incubation medium (Krebs–Ringer phosphate containing glucose) immediately after surgical removal. Slices were cut with a tissue slicer, weighed and transferred to Warburg flasks containing 2 ml. of ice-cold incubation medium. [^{14}C]Dimethylnitrosamine dissolved in medium (0·2 ml. containing 70 μg and 1·89 μCi) was added to each flask. Incubation was at 37° C in an atmosphere of O_2, with shaking, for 100 min, O_2 uptake being measured at 10 min intervals. Radioactive CO_2 was trapped by NaOH in the centre well and its radioactivity determined, after conversion to [^{14}C]$BaCO_3$, by scintillation counting as previously described[9].

Previous studies with rat liver slices *in vitro* showed that the extent of breakdown of dimethylnitrosamine was directly proportional to the amount of tissue as well as to the time of incubation[7]. In the present experiments (Table 1) the weights of the tissues were roughly the same and the time of incubation was constant, which allowed comparison of the results obtained with different tissue slices. The amount of dimethylnitrosamine (70 μg) was well above the level which could be metabolized by the amount of tissue present in each flask[7]. The rate of production of radioactive CO_2 with human liver slices was rather less than with rat liver slices but it was considerably greater than with rat kidney slices (Table 1). Similarly, the level of nucleic acid methylation (Fig. 1) in the human liver slices (0·13 per cent) was slightly lower than in the rat liver (0·19 per cent) but considerably greater than in the rat kidney slices (0·01 per cent). The degree of methylation of the nucleic acids, which is expressed as the percentage of the guanine converted to 7-methylguanine, was calculated as previously described[9].

The higher level of nucleic acid methylation in rat liver than in rat kidney observed *in vitro* is similar to previous findings *in vivo* when the percentages of methylated guanine in nucleic acids of liver and kidney were approximately 1 per cent and 0·1 per cent 5 h after injection of [^{14}C]dimethylnitrosamine (30 mg/kg body weight). In the rat a single dose of dimethylnitrosamine at this level produces a significant incidence of kidney tumours[10] and continuous feeding of this carcinogen induces liver tumours even with concentrations in the diet as low as 5 or 2 p.p.m.[11].

Although the significance of alkylation of nucleic acids in carcinogenesis by nitrosamines is not known, there is a correlation between the levels of methylation in an organ and the distribution of tumours in rats treated with dimethylnitrosamine[9]. These results show that human liver can metabolize dimethylnitrosamine at a rate comparable with rat liver and the similar levels of nucleic acid methylation in the two species suggest that man may be about as sensitive as the rat to the carcinogenic action of this compound. In view of the high carcinogenicity of the nitrosamines and of their presence in the environment, our findings emphasize the potential human hazard from exposure to this group of carcinogens.

We thank Professor Leslie Le Quesne and his colleagues of the Department of Surgical Studies, Middlesex Hospital Medical School, for providing the human liver tissue. This work was supported by a grant from the British Nutrition Foundation Ltd and the British Empire Cancer Campaign for Research. R. M. is a research training fellow of the International Agency for Research on Cancer, Lyon, France.

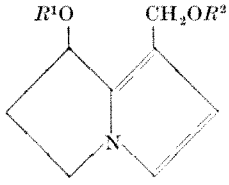
Role of the Acid Moieties in the Toxic Actions of Pyrrolizidine Alkaloids on Liver and Lung



MANY pyrrolizidine alkaloids have toxic effects in the livers and sometimes the lungs of experimental animals[1], and there is evidence that these effects are caused by metabolites formed by enzymic dehydrogenation of the alkaloids in the liver[2–4]. These metabolites are highly reactive dihydropyrrolizine esters which when released

in the liver cell can react with nucleophilic tissue constituents. The heterocyclic moiety can become bound to the tissue while the acid moiety is liberated as the anion.

This implies that the acid moiety may play only a secondary part in the toxic reaction. Yet alkaloids with the same basic moiety, esterified with different acids, have widely different toxic effects[1]. Thus retrorsine, monocrotaline and the semisynthetic diisovaleryl retronecine[5,6], all esters of retronecine (I, $R = H$), have to be administered to rats in doses of about 35, 120 and 500 mg/kg body weight respectively to produce comparable liver damage, while diacetyl retronecine (I, $R = Ac$) has to be given in doses above 900 mg/kg together with an esterase inhibitor to produce liver necrosis (my unpublished results). Moreover, of these compounds, only monocrotaline consistently damages the lungs as well as the liver.

(I)

(II)

Characteristic toxic effects in the lungs and livers of rats have been produced by intravenous injections of chemically prepared dihydropyrrolizine derivatives[2] into the tail vein (5 mg/kg) or a mesenteric vessel (15 mg/kg) respectively[7]. Similar doses of retrorsine pyrrole and monocrotaline pyrrole gave identical effects in both organs, but retronecine pyrrole (II, $R^1 = R^2 = H$), which has weaker alkylating ability[3], was ineffective. To test the importance of the acid moiety, diacetyl retronecine pyrrole (II, $R^1 = R^2 = Ac$) was prepared by acetylating retronecine pyrrole. This compound, when injected intravenously into rats, produced lesions identical to those given by retrorsine and monocrotaline pyrroles at similar dose levels. Like the other dihydropyrrolizine esters it had high alkylating reactivity and was strongly bound to lung and liver tissues after injection. I have previously shown that a crude mixture containing monoacetyl pyrrole derivatives, such as II ($R^1 = Me$, $R^2 = Ac$), can cause the characteristic lung lesions[2].

Thus the qualitative and quantitative differences in toxic effects produced by different alkaloids having the same base moiety (retronecine) but different acid moieties, are not found when the corresponding pyrrole derivatives are applied directly to the appropriate organs. The differences between the alkaloids seem to be due to (1) the different amounts which are metabolized to pyrrole derivatives, and (2) different stabilities of the reactive metabolites in the liver cells. Both these factors are influenced by the acid moieties. The latter can affect distribution of the alkaloids, binding to metabolizing enzymes, and ease of hydrolysis (leading to detoxication)[1]. The alkaloids are apparently not metabolized by lung tissue (unpublished results of I. White and myself). For lung damage to occur, sufficient reactive metabolite must be transported from liver to lungs. The concentrations of pyrrole metabolites found in the lungs of rats 2 h after being dosed with monocrotaline or retrorsine were approximately 34 and 7·5 per cent respectively of the amounts found in the livers. Monocrotaline pyrrole is less reactive than retrorsine pyrrole, requiring twice as long as the latter to react completely with 4-*p*-nitrobenzylpyridine (ref. 3); this probably accounts for its better ability to survive while being transported from liver to lungs.

The nature of the acid moiety seems to be unimportant at the sites of the toxic reactions themselves, for acetate, which is physiological, can be as effective as the complex acids of the natural alkaloids when incorporated in the reactive metabolite. Thus it may be inferred that it is reactions of the dihydropyrrolizine moiety with tissue constituents which are responsible for the toxic effects.

Stability of Cardiac Monoamine Oxidase Activity after Chemical Sympathectomy with 6-Hydroxydopamine

Monoamine oxidase (MAO) of sympathetically innervated organs has been classically considered to be involved in the regulation of intraneuronal catecholamine concentrations. This function of MAO implies that the enzyme is located within the presynaptic element of the adrenergic neuroeffector system. Recent studies, however, have indicated that MAO may be located extraneuronally[1,2].

To confirm these findings we performed a chemical sympathectomy, using 6-hydroxydopamine (6-OH-DA) because of its relative specificity in producing a total sympathectomy of most peripheral organs[3,4]. Data from experiments measuring catecholamine concentrations and tyrosine hydroxylase activity after the administration of 6-OH-DA support the evidence that a complete chemical sympathectomy has taken place[5].

Male Sprague–Dawley rats (5 weeks old, 100–125 g) were given four intravenous injections of 6-OH-DA. The first two injections (50 mg/kg of the salt in 0·01 N HCl bubbled with nitrogen) were given 8 h apart, as were the second two injections (100 mg/kg) 7 days later. Control animals received four intravenous injections of the acid bubbled with nitrogen on the same schedule. Animals were killed 1 day, 5 days or 14 days after the second series of injections and the hearts were removed, blotted dry and placed on ice. The cardiac MAO activity was determined using 5-hydroxytryptamine as a substrate according to the procedure of Weissbach *et al.*[6]. Cardiac noradrenaline concentrations were measured by the method of Chang[7], as modified by Maickel *et al.*[8].

The MAO activities of hearts from rats treated with 6-OH-DA did not vary significantly from controls 1 day after the second series of injections (Fig. 1). Enzyme levels determined 5 days and 14 days later were also well within the control range. Cardiac noradrenaline was not detectable 1 day after the last injection of 6-OH-DA (control, $0{\cdot}48 \pm 0{\cdot}09$ μg/g; 6-OH-DA pretreated, $< 0{\cdot}10$ μg/g). Groups of rats of different ages were also tested; the cardiac MAO activities are not reported because they also failed to show any changes in activity. The use of kynuramine as a substrate for measuring MAO activity did not reveal any changes in the enzyme level following 6-OH-DA (unpublished observation).

The dramatic drop in noradrenaline concentrations indicates that 6-OH-DA did produce a chemical sympathectomy of the heart, especially in view of the reports of the loss of tyrosine hydroxylase activity in rat heart after administration of 6-OH-DA[5]. If 6-OH-DA produces a chemical sympathectomy as stated by various workers, it may have been assumed that cardiac MAO activity would also decrease, especially if the enzyme is localized intraneuronally. The failure of 6-OH-DA to lower the MAO activity in rat heart is of special interest because it

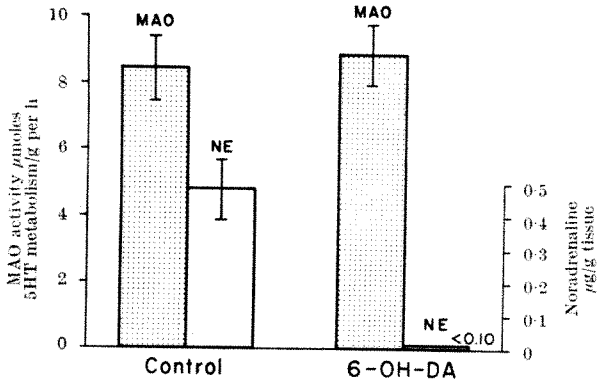

Fig. 1. Cardiac monoamine oxidase activities and noradrenaline levels in control rats and in rats 1 day after the administration of 6-OH-DA. Enzyme activity was determined on individual rat hearts of controls, or of 6-OH-DA pretreated animals (four or five per group). Noradrenaline levels were assayed on individual rat hearts (three per group) of both groups. Results are expressed as the mean ± the standard deviation of the mean. A t test for differences between groups give a P value of $< 0{\cdot}05$ for the noradrenaline levels.

immediately implies that most of the enzyme is of extraneuronal origin.

Several investigators have indicated an extraneuronal localization of MAO in certain sympathetically innervated organs, but its significance has not been pursued. Immunosympathectomy of the rat with the antiserum to nerve growth factor does not lower cardiac MAO[9]. Surgical denervation, as accomplished in autotransplantation of the heart of the dog, does not abolish cardiac MAO activity[1]. These investigations tend to support our contention that MAO of the heart is not totally intraneuronal. In fact, our results indicate that most of the MAO in the rat heart is extraneuronal. The results of our experiments are not specific only for 5-hydroxytryptamine because the use of kynuramine as a substrate for the MAO assay gives the same results.

The MAO activity of the rat heart is attributable to microsomal and mitochondrial components obtained by differential centrifugation[10], so it is possible that the cardiac MAO normally assayed is composed of different fractions, some contributed from neuronal tissues and others from non-neuronal tissues. Because the preponderance of MAO in the rat heart does not appear to be within the sympathetic nerves, it must be located in some other cellular component of the heart.

The finding that most of the cardiac MAO of the rat is not neuronal suggests a role for cardiac MAO other than that of regulating intraneuronal catecholamine levels. If catecholamines are transported across the sarcolemma of cardiac cells in their normal role as sympathetic neurohumours of the heart, then it would be possible to postulate an intracellular localization of MAO in cardiac muscle cells of the rat. The histochemical studies of Mueller and Pearse[11] and the differential centrifugation studies of deChamplain *et al.*[10] indicate that mitochondria and microsomes are the most likely subcellular locations of MAO in the rat heart.

Effects of Morphine and its Antagonists on Release of Cerebral Cortical Acetylcholine

Several studies have shown that the narcotic analge morphine and morphine-like compounds reduce t release of acetylcholine (ACh) at peripheral cholinerg junctions[1–3], but there is relatively little evidence that th have a similar action on the central nervous syste Beleslin and Polak[4] have shown that an intraventricul infusion of morphine in the anaesthetized cat leads to modest decrease in the release of ACh into the cereb spinal fluid. The morphine antagonists nalorphi ('Nalline') and levallorphan ('Lorfan') have been sho to reduce ACh released from the ileum of the guinea-p but a comparable action on the release of ACh from t brain has not been demonstrated. There is evidence th the brain contains a system of cholinergic neurones wi terminals which project to the cerebral cortex[5,6] a release ACh at the cortical surface[7]. If morphine impair the release of ACh at the cortical level, and if this acti was antagonized by narcotic antagonists such as lev lorphan, nalorphine and naloxone, such a reversal morphine action by the antagonists could yield importa information about the neurohumoral changes associat with the hyperactive state which follows the acute wit drawal of morphine in animals and man[8]. We ha therefore investigated the action of morphine on the cor cal release of ACh and compared this action with th of morphine antagonists.

Twenty-two adult cats were anaesthetized with sodiu pentothal and the anaesthetic was continued until t end of surgical procedures, when the animals were mai tained under very light 'Dial' anaesthesia (Dial Co pound, Ciba Ltd, 0·4 ml./kg). ACh was collected bilat ally for 15 min periods from the exposed sensorimotor a left auditory cortices in 'Perspex' cylinders, filled wi artificial cerebrospinal fluid[7] which contained 5×10^{-5} g/n of neostigmine bromide, and rested lightly on the corte After several control samples had been collected, morphi was applied topically on one side only and sampli continued from both sides. In most experiments morphi was injected intravenously following a noticeable effect morphine, topically applied onto one sensorimotor corte when ACh was released from both cortical hemisphere Antagonists were administered intravenously. AC released in the cylinders was assayed biologically on hear from the bivalve mollusc, *Mercenaria mercenaria*. Aft assaying, the hearts were treated with an ACh antagonis benzoquinonium ('Mytolon'), and the samples we re-tested to ensure that responses to both standard a unknown solutions were abolished.

Fig. 1*A* (i, ii and iii) illustrates an experiment in whi topical applications of morphine (1 in 1,000 and 1 in 10 to the right sensorimotor cortex reduced the resti release of ACh not only from the ipsilateral side but al from the contralateral cortex. To rule out the possibili that morphine was reducing the output of ACh on t contralateral side by depressing neural activity in t transcallosal pathway, the resting output of ACh w monitored simultaneously from the contralateral audito

cortex, an area of the brain not connected transcallosally to the morphinized sensorimotor cortex. Fig. 1*A* (iii) shows that there was a parallel decrease in the release of ACh from the auditory cortex. This result suggests that the contralateral effect of topical morphine may have been caused by absorption of the drug into the systemic circulation. Concentrations of morphine lower than 1 in 1,000 did not significantly affect the release of ACh on either side.

The results obtained with drugs administered intravenously are summarized in Table 1. Morphine in doses of 0·1, 1·0 and 5·0 mg/kg consistently reduced the resting release of ACh both in animals which were respiring spontaneously and in those undergoing artificial ventilation. After a reduction of ACh release by morphine to very low levels, levallorphan (5 mg/kg) restored the output to control levels (Fig. 1*B*, i and ii). Subsequent injections of morphine had no effect on release. Small doses of levallorphan (0·1, 1·0 mg/kg) alone decreased the release of ACh as did morphine, but they did not antagonize the effects of morphine. Naloxone itself did not decrease ACh release when given in doses of 0·1 or 1·0 mg/kg, but it readily antagonized the reduction in ACh release induced by morphine or levallorphan. Nalorphine produced effects which were essentially similar to those produced by naloxone in that, in doses of 0·1–5·0 mg/kg, it antagonized the actions of morphine but did not itself reduce the release of ACh.

These findings suggest that morphine depresses the resting cortical release of ACh when applied topically or given systemically. Levallorphan, which is a partial agonist, shares this property with morphine when given in small doses, but antagonizes the depressant effects of morphine in higher doses. Naloxone, which has been claimed to be a true antagonist of morphine[10], does not affect the output of ACh by itself in doses up to 1 mg/kg but readily antagonizes the depressant action of morphine on the cortical release of ACh. These results have not established the exact site of action of morphine and related drugs on the ACh releasing system in the brain. Such a site of action may involve cholinergic nerve endings located in the cerebral cortex or it may involve deeper elements, located subcortically. Our observations suggest that more than one site of action in the brain may be involved.

The exact significance of this decreased release of cortical ACh in the analgesic response produced by these agents has yet to be ascertained. It seems, however, that the immediate increase in the release of cortical ACh after treatment with a narcotic antagonist is partly responsible for the acute withdrawal syndrome precipitated by the administration of narcotic antagonists to morphinized animals. In view of this it is interesting that ACh antagonists have been recommended to ameliorate the narcotic abstinence syndrome[11].

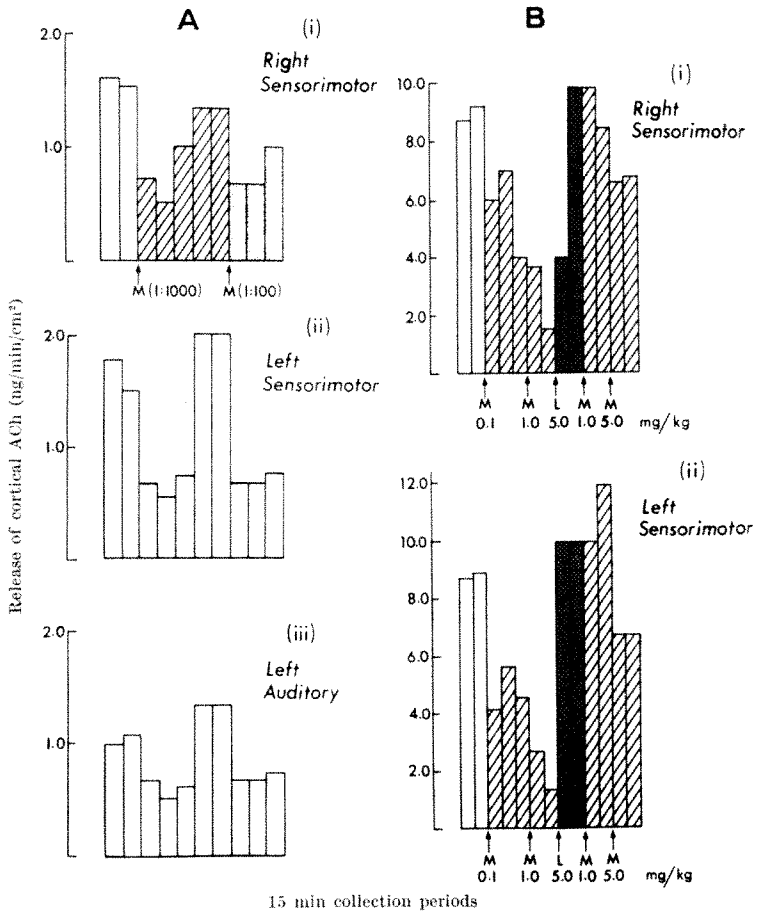

Fig. 1. *A*, Rates of release of ACh from different cortical areas of a cat anaesthetized by 'Dial' compound. Cups were placed bilaterally on the sensorimotor cortices and on the left auditory cortex. At the points indicated by the arrows the ACh collections were interrupted while morphine solutions (1 : 1,000 and 1 : 100) were placed in the cylinder over the right sensorimotor cortex for periods of 30 min. These solutions were replaced at frequent intervals during the periods of exposure. Collections of ACh from the three areas continued after a 5 min period during which the surface of the right sensorimotor cortex was washed repeatedly. *B*, Rates of release of ACh from (i) right sensorimotor cortex and (ii) left sensorimotor cortex after intravenous injections of morphine (M) and levallorphan (L). There was a 5 min break between collections following each drug injection. Actual doses (in mg/kg) of morphine and levallorphan are indicated on the figure.

Table 1. EFFECTS OF INTRAVENOUSLY ADMINISTERED DRUGS ON CORTICAL RELEASE OF ACh

Drug	Release of cortical ACh (ng/min/cm²) Control*	In first 15 min after administration	In second 15 min after administration
Morphine sulphate, 1·0 mg/kg; 12 hemispheres	3·41 ± 0·74	1·30 ± 0·25	0·76 ± 0·16
Levallorphan tartrate, 0·1 mg/kg; 6 hemispheres	2·94 ± 0·87	0·74 ± 0·27	0·91 ± 0·38
Naloxone hydrochloride, 1·0 mg/kg; 4 hemispheres	4·03 ± 0·29	4·75 ± 0·74	5·0 ± 0·57
Nalorphine hydrochloride, 1·0 mg/kg; 4 hemispheres	1·95 ± 0·09	1·95 ± 0·18	2·95 ± 0·61

* Control release represents average of release during two 15 min periods immediately preceding drug administration. Post-drug administration collections commenced 5 min after injection. Values ± standard error.

Production of Poly-unsaturated Ruminant Body Fats

THERE seems to be a significant relationship between serum cholesterol concentrations and the incidence of atherosclerosis in man[1-4]. In the past, considerable attention has been focused on the possible relationships between the consumption of ruminant products (for example, lamb, beef, milk, butter, cheese and cream), high concentrations of serum cholesterol and coronary heart disease in man[5]. These relationships have been attributed largely to the relatively high proportions of saturated fatty acids that occur in ruminant fats, and the possible role of these fatty acids in increasing serum cholesterol concentrations[6,7]. Moreover, it is now firmly established that the substitution of poly-unsaturated fats for saturated fats in human diets will cause a reduction in the concentration of serum cholesterol[5-10]. For these reasons, ruminant fats are largely excluded from the diets of patients being treated for coronary heart disease[5,11]. The availability of poly-unsaturated ruminant products would therefore assist in the formulation of special diets for experimental work and for therapeutic use in patients with atherosclerosis.

It has not been possible, in the past, to increase the proportion of poly-unsaturated fats in ruminant animals by feeding poly-unsaturated oils or by intraruminal infusion of these oils[12,13]. This is because the oils are extensively hydrogenated by the microorganisms present in the rumen[14-16]. If the oils are administered into the abomasum or small intestine, to by-pass the rumen and escape hydrogenation, however, there are substantial increases in the proportion of poly-unsaturated fatty acids in ruminant adipose tissues[13,17].

A procedure has been described for protecting dietary supplements of poly-unsaturated fatty acids from ruminal hydrogenation; when these supplements were fed to lactating ruminants there were substantial increases in the proportion of poly-unsaturated fatty acids in the milk fat[18].

Here we show that feeding these special supplements of poly-unsaturated oils will cause an increase in the proportion of C_{18} poly-unsaturated fatty acids in ruminant depot fats.

Poly-unsaturated lipid-protein particles were prepared by spray-drying a homogenate consisting of equal parts by weight of safflower oil (75 per cent linoleic acid) and sodium caseinate[18]. This procedure stems from previous work on the production of butter powders[19]. The lipid-protein particles (approximate size 15–50 μm) were protected against ruminal hydrogenation by spraying with formalin (37 per cent formaldehyde)[18,20], at a rate of approximately 50 ml./kg of powder. To ensure uniform treatment with formalin, the particles were sieved through a fine screen into the top of a cylindrical tower (3·6 m high and 0·75 m in diameter). As the particles descended through the tower, they were treated with formalin vapour which was introduced into the system through four injection ports located approximately half-way up on the wall of the tower. The formalin treated particles were collected and stored in sealed polyethylene bags for at least 24 h.

Six lambs (8–10 weeks old) were fed daily a pelleted diet of chopped lucerne hay and oats (800 g, 1:1 w/w) and formaldehyde treated safflower oil-protein particles (200 g). Two control lambs of similar age were fed a diet of chopped lucerne hay and wheaten hay (1,000 g/day). All lambs consumed approximately 85–90 per cent of the ration offered. Half of the lambs on each diet were slaughtered after three weeks of feeding; the remainder were killed after 6 weeks. Samples of perinephric, mesenteric and subcutaneous fat were removed, frozen on solid carbon dioxide and transferred into chloroform and methanol (2:1 v/v). The tissues were homogenized, lipid extracts were prepared, and fatty acid compositions determined as previously described[21].

The results in Table 1 show that feeding formaldehyde treated safflower oil supplements caused a 3 to 5-fold increase in the proportion of C_{18} di-unsaturated fatty acid in the depot fats; the greatest increase was observed in the perinephric fat. The change that was induced by feeding the supplement for 6 weeks was not greatly different from that after 3 weeks. This suggests that in lambs of this age there is a fairly rapid exchange between the fatty acids of plasma triglycerides and depot fats. The fatty acid compositions of fats from the control lambs were similar to those reported previously[22,23]. Preliminary analyses on the fatty acid composition of muscle show that the proportion of linoleic acid in the triglycerides is also significantly increased and the values are similar to that obtained for subcutaneous fats. Further studies are required to examine the relation of poly-unsaturated fatty acid concentration in tissues to the dietary intake of protected lipid. Possibly higher levels than those reported here could be attained in a shorter period of time. Comparable experiments with beef animals (12 months old) have shown that the proportion of poly-unsaturated fatty acid is significantly increased after feeding protected lipids for 4 to 8 weeks.

The results show that it is now possible to produce poly-unsaturated ruminant fats by feeding diets containing formaldehyde treated safflower oil-protein particles. Using these procedures it is only necessary to feed the animals for a few weeks before slaughter to produce significantly elevated proportions of poly-unsaturated fatty acids. Although in these experiments only safflower oil was used, the principle would be applicable to other oils (sunflower, soybean, linseed).

The availability of poly-unsaturated ruminant meats (for example, beef, veal, mutton and lamb) and dairy products[18] should offer patients who are being treated for cardiovascular diseases a greater variety of edible

Table 1. FATTY ACID COMPOSITION OF FATS FROM LAMBS ON A DIET CONTAINING SUPPLEMENTS OF FORMALDEHYDE-TREATED SAFFLOWER OIL-PROTEIN PARTICLES

Fat	Period of feeding (weeks)	Treatment	Fatty acid* (weight per cent) 14 : 0	16 : 0	16 : 1	18 : 0	18 : 1	18 : 2†	18 : 3†

Prostaglandin E_1 and the Release of Growth Hormone *in Vitro*

THE presence of prostaglandins in the hypothalamus of the dog[1] raises the interesting possibility that they are important in regulating the release of pituitary hormones. This possibility is strengthened by the demonstration that prostaglandin E_1 (PGE_1) acts on the anterior pituitary *in vitro*, activating adenyl cyclase and increasing the concentration of adenosine 3′5′-cyclic monophosphate (3′5′-AMP)[2]. Theophylline also increases the concentration of 3′5′-AMP in the anterior pituitary, by inhibiting cyclic nucleotide phosphodiesterase[3], and has been shown to stimulate the release of growth hormone *in vitro*[4]. If the increase in 3′5′-AMP in the tissue mediates the stimulation of release by theophylline, prostaglandin E_1 should also stimulate release. The effect of PGE_1 on the release of growth hormone has therefore been determined using the incubation system and radioimmunoassay which I have described before[5].

Pituitary slices, obtained from heifers[4], were incubated at 37° C during transport to the laboratory in 100 ml. of bicarbonate buffered salt solution[6] which had been gassed with oxygen: carbon dioxide (95: 5) and which contained glucose, sodium hydroxybutyrate and sodium glutamate at 0·26 mM. The slices were then divided along the midline and pairs of half slices were incubated with shaking in 3 ml. of the same medium for 30 min. They were then distributed among 10 ml. flasks containing 3 ml. of the same medium and the appropriate concentration of PGE_1, and incubated at 37° C for 45 min. In a second series of experiments the incubation medium also contained 0·5 mM theophylline at this stage. At the end of the incubation the slices were removed, blotted and weighed, and the incubation medium was centrifuged at 3,000*g* for 5 min, and a 50 μl. sample was diluted for growth hormone assay[5].

Table 1. EFFECT OF PGE_1 ON RELEASE OF GROWTH HORMONE IN THE ABSENCE OF THEOPHYLLINE

Concentration of PGE_1 (M)	Rate of release of growth hormone (μg/mg wet weight/h)
0	1·63 ± 0·09
5×10^{-8}	1·46 ± 0·17
5×10^{-7}	1·70 ± 0·13
5×10^{-6}	2·12 ± 0·12*

Results are expressed as mean standard error of the mean for sixteen slices at each concentration of PGE_1, obtained from three pituitary glands.
* $P < 0·005$ compared with control without PGE_1.

Table 2. EFFECT OF PGE_1 ON RELEASE OF GROWTH HORMONE IN THE PRESENCE OF THEOPHYLLINE

Concentration of PGE_1 (M)	Rate of growth hormone release (μg/mg wet weight/h)
0	0·94 ± 0·08
5×10^{-8}	1·53 ± 0·12*
5×10^{-7}	1·70 ± 0·14*
5×10^{-6}	1·40 ± 0·08*

Theophylline (0·5 mM) was present in all samples. Results are expressed as mean standard error of the mean for sixteen slices at each concentration of PGE_1, obtained from four pituitary glands.
* $P < 0·005$ compared with control without PGE_1.

The effect of PGE_1 on the release of growth hormone is shown in the tables. In the absence of theophylline, PGE_1 increased the release of growth hormone by about 30 per cent ($P < 0·005$) in the largest concentration tested (5×10^{-6} M) but had no effect in lower concentrations (Table 1). In the presence of theophylline, the release of growth hormone was increased at a PGE_1 concentration of 5×10^{-8} M, and a maximum increase of about 80 per cent ($P < 0·005$) was obtained at 5×10^{-7} M (Table 2). The ability of theophylline to lower the effective dose and potentiate the action of PGE_1 is to be expected if 3′5′-AMP is involved in growth hormone release, for PGE_1 activates pituitary adenyl cyclase[2] and theophylline inhibits pituitary cyclic nucleotide phosphodiesterase[3]. PGE_1 has been shown to increase *in vivo* release of insulin[7] and ACTH[8], and there are conflicting reports of its effects on the release of catecholamines[9,10]. My finding that PGE_1 stimulates the release of growth hormone *in vitro* demonstrates that stimulation by PGE_1 is not specific to one cell type or to one hormone. Prostaglandins may function as modulators of the action of the well documented hypothalamic releasing factors at the pituitary receptor level, in the same way as they have been proposed as modulators of the action of transmitters in smooth muscle[11]. It is perhaps relevant that lipid extracts of the hypothalamus have been reported to cause weight gain in young rats[12].

I thank Miss Rita Ruddy for technical assistance, and Professor P. J. Randle for advice and encouragement. The work was supported by grants from the British Diabetic Association and the British Insulin Manufacturers to Professor Randle. Prostaglandin E_1 was a gift from Dr J. E. Pike of the Upjohn Company, Kalamazoo, Michigan.

Effects of High Levels of Yeast Feeding on Uric Acid Metabolism of Young Men

THE possible use of single cells of yeast and bacteria as food is receiving much attention[1,2]. It has long been recognized[3–9] that feeding yeast can increase urinary uric acid excretion, but the levels of its use in processed foods have been so low that no problems have arisen. If yeast and other single cells are used, however, as sources of protein rather than of vitamins, the intakes involved are much higher.

Man and higher apes lack the enzyme uricase, which catalyses the oxidation of uric acid to the more soluble allantoin, so that in individuals with a genetic tendency to primary over-production of uric acid there may be precipitation of uric acid crystals in joints (gout), soft tissues (tophi) or the formation of stones in the urinary tract. The increase in uric acid secondary to a high intake of dietary purines and other exogenous factors may have a similar effect.

Four healthy male MIT students aged 18 to 27 years, weighing 65 to 90 kg, were fed a controlled, low-purine diet providing adequate calories, minerals, and vitamins together with 100 g of protein and about 11 mg purine nitrogen per day. The subjects received the basal diet for 16 days followed by consecutive 9-day periods with 45, 90, and 135 g of food yeast (*Torula utilis*, NF 12 Type 300, Lake States Division, St Regis Paper Co.) distributed equally among four meals. Total protein intake was maintained at 100 g per day. The weight of the subjects remained constant throughout the experiment.

The experimental diets contributed 2·9, 5·8 and 8·7 g of yeast nucleic acid (DNA and RNA) by analysis[10]. Uric acid was determined[11] on plasma taken at 8.00 h, 11 h after the start of the last meal. Creatinine excretion[12] was measured daily throughout the experiment.

The results in Table 1 show that 45 g of yeast containing 2·9 g of nucleic acid was sufficient to raise the serum uric acid levels of the subjects to approximately 7·0 mg/100 ml. Doubling this quantity increased the uric acid levels of all subjects to unacceptable levels, and tripling it brought about a further but much smaller increase.

The only comparable data are those of Waslien *et al.*[13], who fed healthy young men 0, 2, 4 and 8 g of yeast RNA for 5 consecutive days in a constant 75 g egg-protein diet distributed among four equal meals. The resulting average uric acid levels of 4·9, 6·0, 7·7 and 9·4 mg/100 ml. are similar to ours when allowance is made for differences in the exact level of nucleic acid fed. All five of their subjects fed 2 g of yeast RNA had serum uric acid level which remained within normal limits, while all four of our subjects fed 2·9 g of nucleic acid had levels which were at or slightly above 7·0 mg/100 ml.

Because this is a level which separates most patients with primary gout from most normal subjects[14–16], the combined results for blood uric acid levels suggest that 2 g of single-cell protein (SCP) nucleic acid per day is probably a safe limit to feed most normal subjects, but 3 g of SCP nucleic acid per day might place some normal subjects at risk.

The influence on urinary uric acid excretion of feeding the yeast is shown in Table 1. The lowest level of yeast nucleic acid fed, 2·9 g, increased uric acid excretion to more than 1,000 mg per day, and the additional increase was proportional when nucleic acid ingestion was doubled. A further increase in nucleic acid intake did not produce any consistent further change.

The urinary uric acid excretion values reported by Waslien *et al.*[13] were lower—373, 667, 939 and 1,393 mg per day for the intakes cited previously—but our data suggest that for most normal individuals a daily intake of approximately 3 g of SCP nucleic acid results in undesirably high levels of urinary uric acid because the majority of normal persons on ordinary diets excrete less than 600 mg of uric acid per day[17,18]. A dietary level of 2 g of SCP nucleic acid would seem to involve little risk of stone formation; slightly higher levels probably pose no hazards as long as urine volume and *p*H are not abnormally low. At no time was any gastrointestinal disturbance encountered even at the level of 135 g of yeast per day.

Table 1. EFFECT OF YEAST NUCLEIC ACID ON SERUM AND URINARY URIC ACID IN YOUNG MEN

	Serum uric acid (mg/100 ml.)				Urine uric acid (mg/24 h)			
Yeast fed (g/day)	0*	45	90	135	0*	45	90	135
Yeast nucleic acid intake (g/day)	—	2·9	5·8	8·7	—	2·9	5·8	8·7
Subject number								
1	4·5	7·5	9·2	10·1	533	1343	2007	2100
2	4·7	7·4	9·1	9·9	405	1200	1880	2400
3	4·5	6·8	8·6	8·5	504	1100	1800	1585
4	4·3	7·2	8·5	9·1	599	1125	1725	1400

* 100 g "purine-free" protein per day.
The values for serum and urine uric acid are the means of the values for the 5th, 6th and 7th days of each dietary period.

New Process for Reducing the Nucleic Acid Content of Yeast

It has been shown that if single-cell protein is to be used as a primary protein source for human populations, the nucleic acid content should be reduced to a level which would allow a maximum intake in the range of 2 g of nucleic acid per day[1]. For a processing method to be acceptable, it must not only decrease the nucleic acid level to the required degree, but it must also be inexpensive and must not contaminate the product with undesirable chemicals.

Candida utilis was grown in continuous culture[2] with glucose as the carbon source at *p*H 4·0 and at a dilution rate of 0·19 h^{-1} ($\mu_{max} = 0{\cdot}4\ h^{-1}$). The initial nucleic acid content of the cells in these growth conditions was approximately 7 per cent. After collection, the cells were treated in a three-step heating process to produce cells with 1·0–1·5 per cent nucleic acid and approximately 50 per cent protein. The successive steps involved were: (1) heat shock of a few seconds duration at 54°–70° C; (2) incubation at 45°–50° C; and (3) incubation at 55°–60° C. All three steps seem to be necessary for optimum results although a compromise temperature between 50 and 60° C is possible for the last two steps.

The heat shock was performed by passing a suspension of *C. utilis* in spent medium through a 56 cm length of 1/32 inch inner diameter (1/16 inch outer diameter) stainless steel tubing immersed in a vigorously stirred water bath at the desired temperature. For the remaining steps a nominal residence time of 5·5–6·0 s and a temperature of 68° C were chosen. After heat shocking, the cells were collected at 0° C or were treated immediately at 45°–50° C. The method of collection did not affect the final results.

The data in Fig. 1 indicate an optimum temperature range of 62°–68° C for a heating time of 17 s and an optimal temperature of 68° C for treatments of shorter duration. Other experiments have shown that longer heating times at lower temperatures or shorter heating times at higher temperatures do not lead to an optimal process under any conditions of subsequent incubation. When the heat shock is omitted the remaining two steps result in only a 10 per cent reduction in nucleic acid compared with an 80–85 per cent reduction when heat shock was used. After heat shock alone the nucleic acid content of the cells is not significantly altered.

Recalculation of data presented by Bodley[3] for the rate of *E. coli* ribosome denaturation indicates a half life of 0·6 s at 68° C. Haight and Ordal[4] have shown a ribonuclease associated with staphylococcal ribosomes which is activated by heat and attacks only the RNA closely bound within the same ribosome. The heat shock in our process may serve either or both of these functions. The final two steps probably allow a complex series of enzymatic hydrolysis reactions to occur culminating in the leakage of these products from the cells into the surrounding medium.

One of the principal functions of the third step is to allow leakage of the accumulated hydrolysis products from the cells, but there is also a significant amount of additional hydrolysis of polynucleotides. If the second step is conducted at 45° C there is essentially no leakage of UV absorbing material into the medium in the absence of step 3. The optimal time and temperature of incubation of this third step were found to be 1 h at 55° C when the second step was conducted at 45° C. A slightly higher temperature of 60° C results in poorer nucleic acid removal, possibly because of the denaturation of the endogenous ribonucleases preventing further degradation of polynucleotides or alternatively of the formation of RNA aggregates resistant to enzyme action. The optimum range for the overall process is between *p*H 5·0 and 6·5.

In view of the close similarity between the optimum conditions of heat shock for breakdown of *C. utilis* RNA and the conditions required for irreversible thermal denaturation of *E. coli* ribosomes[3], we expect that our method can be applied to other types of microbial cells. We have begun to scale up the process of *C. utilis* in order to prepare enough product to conduct feeding studies. We are also trying to determine the exact nature of the reactions involved in each of the steps.

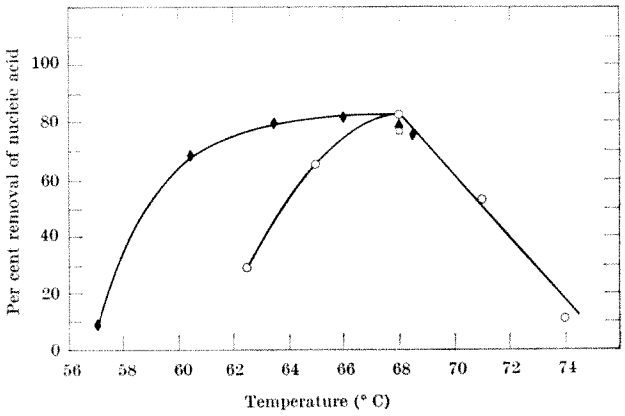

Fig. 1. Effect of heat shock temperature and time on nucleic acid removal. Step 1: variable; step 2: 45° C, 2 h; step 3: 55° C, 1 h. Residence time: ▲, 3 s; ○, 6 s; □, 12 s; ◆, 17 s.

Absence of the Pigments of Photosystem II of Photosynthesis in Heterocysts of a Blue–Green Alga

All filamentous blue-green algae capable of fixing elementary nitrogen have heterocysts. Stewart *et al.*[1] have strong evidence that these differentiated cells are the sites of nitrogen fixation. They did not, however, show that photosystem II, responsible for the evolution of molecular oxygen (O_2), is not functional in heterocysts. Because high oxygen tension inhibits nitrogen fixation, heterocysts should not possess the pigments of photosystem II. Fay[2] produced evidence *in vitro* suggesting that heterocysts do not contain c-phycocyanin (c-PC), a principal constituent of photosystem II. Stewart *et al.*[1] found much less c-PC in heterocysts than normal cells and believed that photosystem II could be absent in heterocysts. Others[3,4], however, have demonstrated the evolution of O_2 from blue–green algae in the absence of c-PC. Thus the points to be resolved are whether heterocysts *in vivo* contain c-PC and the other pigments comprising photosystem II, and whether, in the absence of one or more of these, photosystem II is functional in heterocysts. A comparison of the *in vivo* pigment composition of normal cells and heterocysts has indicated that heterocysts lack a functional photosystem II.

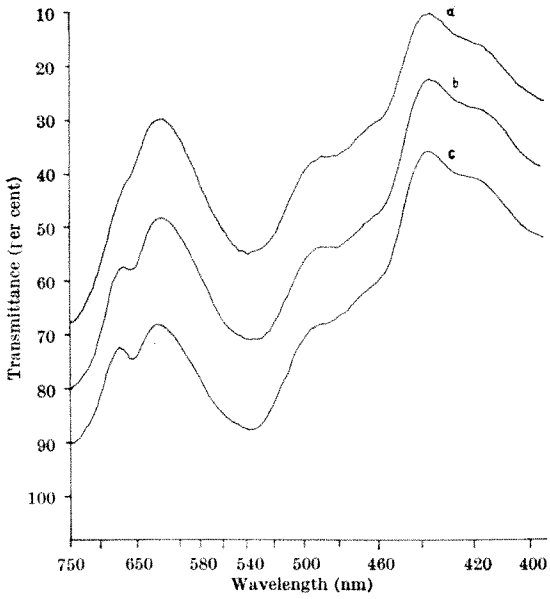

Fig. 1. Typical absorption spectra of single normal cells of *Anabaena* sp. L-31: (*a*) very young cells, (*b*) young cells and (*c*) old cells spectra. *a* and *b* are superposed by twenty and eight divisions respectively in percentage transmittance scale to facilitate comparison.

Anabaena sp. L-31 was grown in batch and continuous cultures in Watanabe's medium[5] without combined nitrogen. Cultures were aerated at a rate of 5 l./min. Light intensity was about 5,000 lux, and the algal suspension was 5 cm deep. The temperature was maintained at $29 \pm 1°$ C. Details of the continuous culture procedure have been reported before[6]. Samples were pipetted out aseptically and either centrifuged, washed and suspended in 50 per cent glycerol or directly mounted on quartz slides.

I used the microspectrophotometric technique, which is suitable[7] for the *in vivo* determination of the spectral characteristics of the pigments of single algal cells. Using a Universal Microspectrophotometer (UMSP I, Zeiss), all measurements were made on an area of diameter 3·2 μm in the spectral range 400 to 750 nm on single cells of *Anabaena*. Absorption spectra of nearly 180 normal cells and 80 heterocysts were measured.

Fig. 1*b* shows a typical absorption spectrum of normal cells, which comprised nearly 60 per cent of the population examined. The principal chlorophyll *a* peak is near 666 nm, while the c-PC peak is near 620 nm. C-phycoerythrin (c-PE) is not distinct, except for a slight change of slope of absorption near 580 nm. The absorption maxima due to carotenoids are near 490 and 460 nm. The spectrum in Fig. 1*a* is characteristic of very young cells constituting nearly 18 per cent of the total population and is distinctly different. The chlorophyll *a* (Chl *a*) and c-PC peaks are not well separated. Allophycocyanin (allo-PC) absorbing near 650 nm has been shown to be present in blue–green algae[8,9]. In young cells there seems to be more allo-PC. Absorption near 650 nm is enhanced and in the resultant overall envelope distinct peak characteristics are obliterated. Older cells, constituting nearly 22 per cent of the population, contain less allo-PC, so that there is a progressively deeper trough near 650 nm (Fig. 1*c*).

With the decrease of allo-PC in old cells there is a less drastic decrease in the peaks of Chl *a* and c-PC. Moreover, the Chl *a* peak is then no longer near 666 nm but is close to 680 nm, which indicates that it is the short wave form of Chl *a*, generally referred to as chlorophyll C*a* 670, which is decreasing in quantity.

The typical absorption spectrum of fully differentiated heterocysts characterized by thick walls, distinct polar bodies and homogenous protoplasm is shown in Fig. 2*c*. The chlorophyll peak is much reduced and near 680 nm, demonstrating that the long-wave form of Chl *a* (chlorophyll *a* 680) is present while the short-wave form, chlorophyll *a* 670, is absent. The peak of c-PC is absent, or, when present, appears as a very small hump. Peaks due to allo-PC and c-PE are also absent. The carotenoid peaks near 490 and 460 nm are, however, present and there is no significant change in their heights.

Spectrum 2*c* is typical of heterocysts of *Anabaena* grown in continuous culture and in samples examined during the exponential phase of batch cultures when light-saturated growth is prevalent. But in samples collected from batch cultures during the late linear phase of growth when growth is limited by light, heterocysts with distinctly different spectral features are observed (Fig. 2*b*). Under the microscope, these appear more opaque than those visible before. c-PC is present, but in much smaller quantities than normal. c-PE is also present. Low light intensities seem to favour the synthesis of biliproteins in heterocysts, as in normal cells of other blue–green and red algae[10,11]. Allo-PC seems to be absent, causing a deep fissure in the absorption curve near 650 nm. The chlorophyll peak is much reduced and is near 680 nm, which suggests that chlorophyll *a* 670 is not present.

These results indicate that heterocysts have two distinct types of spectral characteristics depending on culture conditions. But all heterocysts, irrespective of type, seem to lack the short-wave form of Chl *a* and allo-PC (Table 1). The range in the wavelength of absorption maxima of Chl *a* peak in the normal cells is between 662 and 672 nm, with a mean at 666 nm. In heterocysts the range falls within 678 to 685 nm, with the average value at 681 nm.

Table 1. WAVELENGTH OF MAXIMUM ABSORPTION OF CHLOROPHYLL *a* IN NORMAL CELLS AND HETEROCYSTS OF *Anabaena* sp. L-31

Normal cell		Heterocyst	
Range in λ max. (nm)	Mean λ max.* (nm)	Range in λ max. (nm)	Mean λ max.† (nm)
662–672	666	678–685	681

* Average value obtained from 179 measurements.
† Average value obtained from 76 measurements.

Photosystem II of blue–green algae responsible for the evolution of molecular O_2 is chiefly composed of c-PC and Chl *a* 670. The accessory pigments allo-PC and c-PE are also thought to be involved. It is generally believed

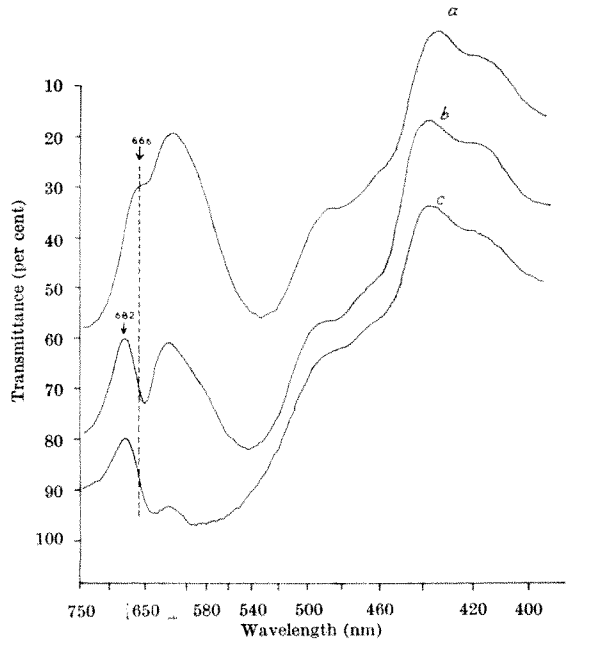

Fig. 2. Absorption spectral characteristics of single normal cells and single heterocysts of *Anabaena* sp. L-31. Typical spectra of (*a*) a normal cell, heterocysts in (*b*) light limited and (*c*) light saturated growth respectively. Spectra *a* and *b* are superposed by thirty-three and seven divisions respectively in percentage transmittance scale to facilitate comparison.

that the energy absorbed reaches the reaction centre by sequential resonance transfer between pigments with overlapping absorption bands, down the gradient from the region of higher energy (shorter wavelengths, accessory pigments) to regions of lower energy (longer wavelengths, chlorophyll *a*)[12]. In blue–green algae the sequence would be

c-PE→c-PC→allo-PC→Chl *a* 670→reaction centre

Even when c-PC is present, as in the second type of heterocysts, the absence of allo-PC and chlorophyll *a* 670 would seriously hamper energy transfer. Photosystem II, responsible for the evolution of molecular O_2, thus may not be functional in heterocysts.

The presence of chlorophyll *a* 680 and carotenoids indicates that photosystem I exists in heterocysts. Goedheer[13] showed that in blue–green algae energy transfer from β-carotene to chlorophyll occurs exclusively in photosystem I. This suggests that in heterocysts there is a functional photosystem I and that ATP generated by cyclic photophosphorylation can promote the reduction of nitrogen.

The evolution of O_2 observed by others[3,4] in the absence of c-PC in normal cells of blue–green algae is compatible with our results. Even if c-PC is absent, molecular O_2 would still be evolved under white light in the presence of chlorophyll *a* 670. The findings that both chlorophyll *a* 670 and allo-PC are invariably absent in heterocysts and that a functional photosystem I is present suggest that these differentiated cells would be ideal sites for nitrogen fixation in blue–green algae.

I thank Dr A. R. Gopal-Ayengar for encouragement and interest.

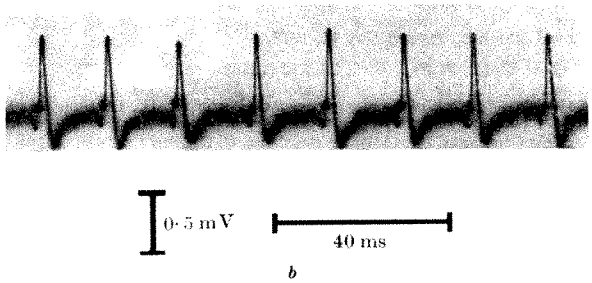
Internal Muscle in the Eye of an Insect

THE muscles associated with the vertebrate eye are well known, comprising those responsible for eye movements and the muscles within the eye controlling the iris and lens. The compound eyes of insects form part of the head capsule, and movements of the eye as a whole seem to demand that the whole head be moved as in the peering movements of young locusts[1]. There is only one little-known reference to a muscle within the compound eye itself, in the blowfly *Calliphora*[2]. Lowne called it a "ciliary muscle", but only noted its outer attachment. Fig. 1*a* shows that the muscle is attached externally to the medial border of the membrane at the base of the receptor layer, and internally to the tentorium (the internal supporting structure of the insect head). It is supplied by a fine branch of the antennal nerve. We have found comparable muscles in other Diptera, for example, syrphids, tipulids and culicids.



Extracellular recordings using a 30 μm tungsten electrode in contact with the muscle have been made in several species of syrphids, but mostly in *Calliphora vomitoria* L. The responses of the muscle in the intact head consist of a repetitive discharge of potentials of up to 1 mV amplitude and 25–100 Hz frequency (Fig. 1*b*). These potentials, to judge from their complex wave form, change in frequency with temperature and position of recording, and are the same as those described in *Calliphora erythrocephala* by Leutscher-Hazelhoff and Kuiper as "clock spikes"[3]. They described them as coming from the optic ganglion, but as the muscle is near the optic lobe (Fig. 1*a*) this location of the response could be due to electronic spread. They did not find any response to light.

We have found a marked response to light. Fig. 2*a* refers to flies which were adapted to white tungsten light of 6,500 lux and suddenly darkened, when there was a sharp increase in the rate of discharge of the muscle (shown by the shorter interspike interval). Conversely, as Fig. 2*b* shows, illuminating a dark adapted eye results in a slower rate of discharge (that is, a longer interspike interval).

Changes in the rate of response of the eye muscle would be expected to change its length and alter the position of structures to which it is attached. The tentorium would be expected to remain relatively static and the base of the eye would be expected to move. Two pieces of evidence suggest that this happens. First, light adapted insects were fixed rapidly while under light of 6,500 lux by injecting Bouin's fluid into the head; and dark adapted insects were fixed in the same way under red light to which

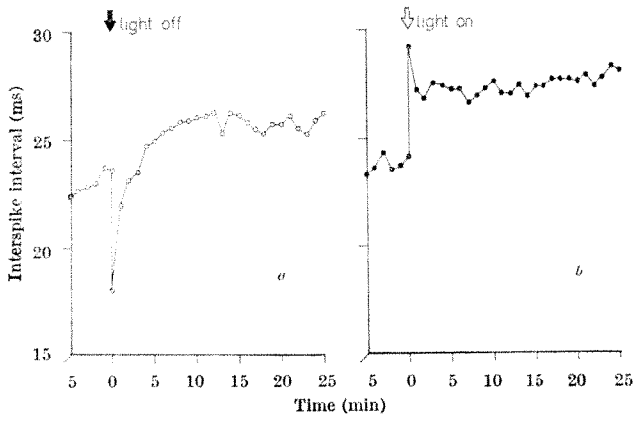

Fig. 2. Interspike interval plotted against time for female *Calliphora vomitoria* L. (means of ten animals). *a*, Light adapted in response to light "off". *b*, Dark adapted in response to light "on".

Calliphora is less sensitive. Frozen sections were compared in two groups each of thirty eyes from female flies by measuring the depth of region X in Fig. 1*a*. This was deeper in the light adapted state—$459 \pm 3{\cdot}9$ against $445 \pm 3{\cdot}5$ μm (s.d. of mean) in darkness, $P = 0{\cdot}01$–$0{\cdot}002$. Second, the eye was illuminated from within the head as described by Gemperlein and Jarvilehto[4], and the illuminated rhabdomeres were observed by a microscope through the outer surfaces of the eye. Changes in illumination of the eye in these conditions produced readily visible movements of the rhabdomeres.

Changes in the rate of discharge of the muscle can also be caused by moving large striped patterns across the visual field, and (which is rather unexpected) by air currents on the head.

Considering the function of the muscle, we thought earlier that it might cause the proximal migration of the rhabdomeres on adaptation to light first reported in Hemiptera[5] and we have found a similar muscle in Notonecta. Among Diptera, rhabdomere movements have been found in culicids[6], tipulids[7] and chironomids[8]. They also occur in Coleoptera[9]. In *Calliphora*, however, there are no movements of the rhabdomeres relative to the crystalline cone of the eye when the insect undergoes light adaptation. The occurrence of a response in the muscle to moving striped patterns (which in themselves would not cause a change in total illumination on the eye) suggests that the muscle causes scanning movements of the compound eye by displacing the photoreceptors. Movements of the photoreceptors relative to the lens system occur in the eye of salticid spiders[10] and in the copepod *Copilia*[11]; while the importance of small rapid movements of the eyes is seen in the human eye[12] and in the eye-stalks of crabs[13].

Analysis of Running and the Prediction of Ultimate Performance

Several people have attempted to analyse world running records in the hope of explaining why man runs slower as the distance run increases. Meade[1,2] and Lietzke[3–5] have pointed out that the ratio of records for two distances has remained more or less constant since reliable athletic data have been kept. By showing that the rate of running during world record performances varies smoothly with distance (when plotted in logarithmic form), Francis[6] pointed out inconsistencies in the records and predicted which records should be broken and by how much. A physiological approach by Henry[7] yielded a polynomial expression relating mean running speed and total running time. The coefficients of the polynomial were related to the consumption and production of chemicals involved in muscle contraction, for example, glycogen and lactic acid.

Henry's work highlights the defect in all previous approaches in that each attempted to explain the process of fatigue (slowing down with distance) of one man by an analysis of world records set by several men. The hypothesis presented here applies to the fatigue of a single man and yet may explain many of the factors noted earlier, namely, smooth variation of record running rates with distance and the constant ratio of record times for two distances. In particular the success of this analysis allows a realistic estimate of the ultimate running performance.

We assume intuitively that the rate of running decays naturally (exponentially) with distance to be run. The expression

$$V^{-1} = f \ln d + c \qquad (1)$$

where V^{-1} is reciprocal of running rate (min/mile is a convenient unit); d is distance; c is a constant, and f is a constant called "fatigue coefficient", applies to many athletes engaged in aerobic running (distances above 1/4 mile). For example, in Fig. 1 the dotted lines and points demonstrate that equation (1) applies to three well known athletes, J. Ryun (United States, world record holder at 1/2 and 1 mile), R. Clarke (Australia, world record holder at 3 and 6 miles) and R. Hill (Great Britain, world record holder at 10 miles and second fastest marathon runner) and shows how f can vary considerably. Ryun has a high fatigue coefficient of 1·30 which is about double that of Clarke (0·62) while Hill (0·51) has one of the lowest fatigue coefficients we have found. The full line in Fig. 1 shows the smooth current world record curve and the data for Ryun and Clarke show that this arises

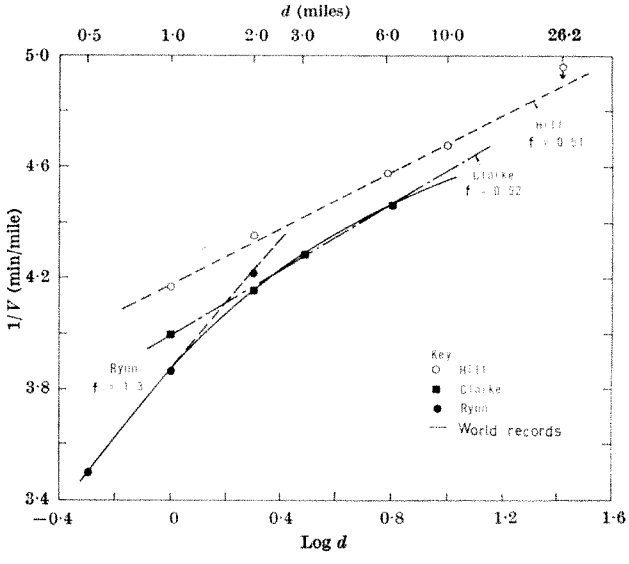

Fig. 1. Equation (1) plotted for three athletes and the current world records. Common logarithms are used.

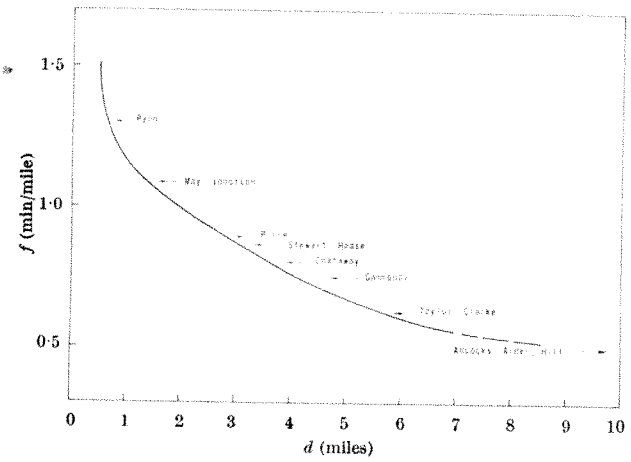

Fig. 2. Variation of f with distance for the current world records. Horizontal arrows indicate the coefficients established for a selection of prominent athletes.

from the overlapping of their individual straight lines; this curve explains the "constant ratio observation". Also, although there is an abrupt break in the world record curve above 6 miles, the linear relationship is retained by an individual up to the marathon distance (for example, Hill). This implies that the present 10 miles track record is slower than it should be.

Tangents to the world record curve at distance d will give the fatigue coefficient of the athlete likely to hold that particular record and thus f will vary smoothly with d. This is shown by Fig. 2 and so are the values of fatigue coefficient determined for several prominent athletes, past and present. Thus Fig. 2 shows effectively the event at which the athlete can perform best—the distance at which the slope of his "straight line plot" most closely approaches the tangent to the world record curve. The athlete has in most cases found by experience at which event he is best, but the significance of this idea to the non-world class or junior athlete is that it provides a means of determining which is his best event and also tells him, for example, whether his 9 min 2 mile run today is as good as his 14 min 3 mile run a month ago.

Equation (1) seems to hold for all runners but breaks down when the exercise is anaerobic. (At distances below about 1/4 mile $f \simeq 0$, that is, there is little loss in speed with distance.) This means that the performance of any aerobic exercise such as swimming or cycling should also obey the hypothesis, and this is found to be so. As the athlete improves, c is reduced and the performance line approaches the anaerobic region. But the data available for mature athletes indicate that f is constant and therefore an innate characteristic of the body.

In adult runners maximum running speed is almost invariant and the fatigue coefficient is probably a constant, and so we have a means of estimating the best possible performances of which an athlete is capable; these are the performances which lie on a line that passes through the runner's maximum running rate, for example, his 100 yards rate. Further, we can estimate the ultimate running times by taking the lowest observed fatigue coefficient, $f = 0{\cdot}5$, and a 100 yards time of 9·0 s (0·1 s below the present world record) and using equation (1) calculate the rates and times at other distances from 1/2 mile up to the marathon. The predicted limit of human performance is shown in Table 1 and compared with the present world records. If the present linear improvement in running records continues the ultimate performances should be reached in about 100 yr.

Table 1. ULTIMATE RUNNING PERFORMANCES

Distance (miles)	$f = 0{\cdot}5$ Present world record	100 yards in 9·0 s Ultimate performance
0·5	1 min 44·9 s	1 min 27 s
1·0	3 min 51·1 s	3 min 00 s
3·0	12 min 50·4 s	9 min 43 s
6·0	26 min 47·0 s	20 min 24 s
10·0	46 min 44·0 s	35 min 00 s
Marathon	2 h 8 min 56 s	1 h 37 min 30 s

Quantitative Assessment of the Flight of *Archaeopteryx*

The coracoids, humeri and sternum of *Archaeopteryx* indicate that it was a poor flier[1]. Recent work on pigeon flight[2] suggests that an analysis of the strength of the wing bones should allow a quantitative evaluation of the flight potential of *Archaeopteryx*. While Pennycuik's experimental techniques could not be used, a theoretical approach seemed feasible.

The bones which are subjected to the highest stresses in flight are the humeri because these have to bear the total lift force. I decided to calculate the maximum bending moment which the humerus in *Archaeopteryx* could tolerate and from this to determine the ultimate load factor of the wings.

The shaft of the humerus is almost circular in cross-section and its narrow distal end approaches a cylindrical form. This bone was not pneumatic[1] and it was therefore assumed that the distal end was solid. The equation relating the maximum bending moment M to the tensile strength of the bone T and its radius r is as follows[3]

$$M = \frac{T\pi r^3}{4}$$

The radius at the narrowest portion (both London and Berlin specimens) is 0·15 cm and T is taken as $1{\cdot}3 \times 10^9$ dynes/cm^2, this being the highest recorded value[4,5].

The maximum bending moment of 3,500 g cm which the humerus could sustain can be related to flight performance if the weight and the position of the centre of lift are known. I agree with Jerison's estimate[6] of 500 g for the weight. Locating the centre of lift and relating this to the orientation of the humerus requires an accurate reconstruction of the wing profile. That shown in Fig. 1

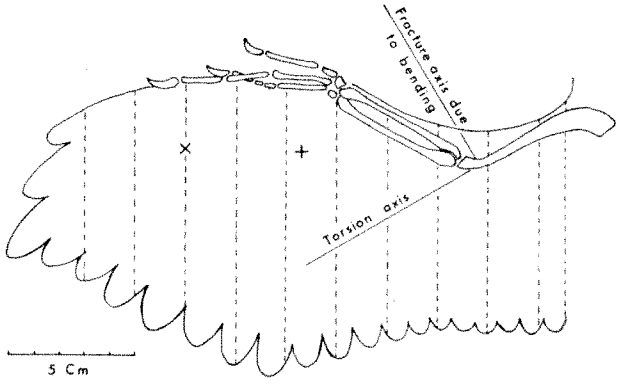

Fig. 1. Wing of *Archaeopteryx lithographica* spread out in the manner adopted during flight. Dashed lines divide the wing up into the eleven strips which were used in calculating the positions of the centre of lift while gliding (+) and hovering (×).

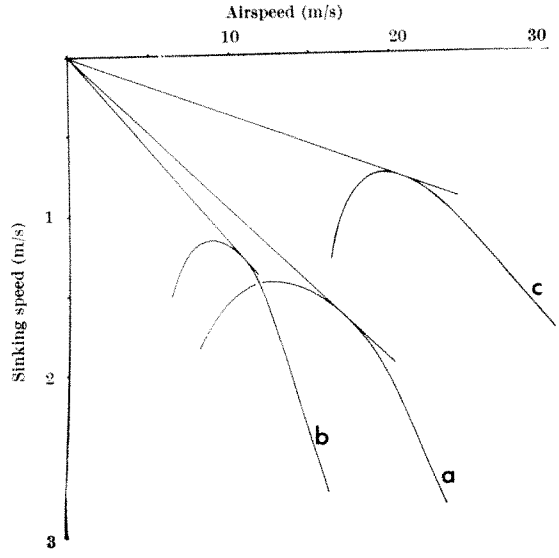

Fig. 2. The gliding polar illustrating the relationship between sinking speed and airspeed for (*a*) *A. lithographica*, (*b*) the fulmar petrel and (*c*) a typical man-made glider (*b* and *c* after Pennycuik[10]). The tangent to each curve shows the best gliding angle.

is based on the known feather pattern[1]. The centres of lift for gliding and hovering were located using Pennycuik's method[2] of dividing the wing into strips and calculating the lift generated by each strip. After locating the centres, the humerus was re-oriented slightly so that the ratio of the distances to the fracture axes was the same as that for the pigeon. In this configuration the humerus would have offered maximum strength to bending and torsion[2].

Considering first gliding flight, the distance from the centre of lift to the suggested fracture axis caused by bending is 5·9 cm, giving a maximum permitted lift on each wing of 590 g. We can ignore the lift which could be generated by the large tail, because, in ordinary flight, it would have acted so far back as to seriously upset the animal's balance. If the body also provided negligible lift, then the wing had an ultimate load factor of 2·4. This seems remarkably low and compares very unfavourably with the figure of 8·8 for the pigeon[2]. This weakness must have limited the animal's manoeuvrability, particularly in its circular paths. Assuming that during its tightest turns the wings were subjected to a load factor of 2·0 (that is, 0·4 reserve), then the maximum angle of bank was 60° (ref. 7). The minimum radii of these circular paths can be computed if the velocity is known. This is calculated from the same equation as that used by Bramwell and Whitfield in their analysis of the flying speed of *Pteranodon*[8], that is,

$$v = \sqrt{\frac{2L}{C_L \rho A}}$$

Here the lift L had a maximum value of $9{\cdot}8 \times 10^5$ dynes, the area of the wings A was 373 cm^2, the lift coefficient C_L is taken as 1·0 (that is, a cambered plate)[9], and the density of the atmosphere ρ is assumed to have been the same as at present. The maximum velocity is found to have been 20·9 m/s.

In pursuing a horizontal circular path the horizontal component of lift balanced the centrifugal force from which it is found that the minimum radius was 27·7 m, that is more than eight times that of the pigeon[2]. In pulling out of a dive the wings had to provide sufficient force to balance both centrifugal force and the bird's weight. At the lowest point the lift required to maintain a circular path (radius p) is as follows

$$L = \frac{mv^2}{p} + mg$$

The minimum radius of 44·5 m again compares unfavou ably with the 4·4 m calculated for the pigeon.

The performance of *Archaeopteryx* in gliding flight c be estimated theoretically[7]. The equation relating sinki speed to airspeed at low gliding angles (ø) is

$$r \sin \varphi = \rho \frac{AC_D r^3}{2\ mg} + \frac{2k\ mg}{\pi \rho S A r}$$

where C_D is the drag coefficient at the angle of inciden at which there is no lift, S is the aspect ratio and k is constant. C_D is taken as 0·04, this being the value for cambered plate at Reynolds numbers within the ran of *Archaeopteryx*[9]. According to Alexander[3] k cannot less than 1·0 and this value may be taken for most practic purposes.

The computed curve (Fig. 2*a*) shows the minimu sinking speed to have been 1·5 m/s and the best glidi angle 6°. Compared with fulmars and a typical man-ma glider (Fig. 2*b* and *c*)[10], it can be seen that *Archaeopter* was inferior to both. In view of the high sinking spe it is surprising that its pelvis was not better adapted withstand the impact of landing. De Beer pointed ou that the skeleton in modern birds is increased by t uncinate processes on the ribs, the extensive sacru and the elaborate articulations between the vertebra *Archaeopteryx* had none of these safeguards, from whi he concluded that it could not have landed from a gre height nor at great speed. No matter what method landing was adopted it would have been more viole than that of the fulmar and probably of most mode birds for, as will be shown, flapping its wings would on have produced a fraction of the lift needed for hoverin

Flapping flight imposed greater stresses on the win than gliding because the centre of lift moved further o from the body, the limiting case being reached if hovered. This centre during hovering was 9·8 cm fro the fracture axis caused by bending (see Fig. 1); thus t humerus would have fractured at a wing loading 360 g. In spite of this low figure the wings were stro enough to bear the animal's weight, but the possibili of hovering must be excluded on other evidence. T wings were aerodynamically poor because the long cla on the leading edge would have disrupted the air flo Taking a maximum lift coefficient of 1·5 it is calculat that in order to hover, *Archaeopteryx* would have had flap its wings at 20 beats/s, that is, more than twice t rate of a pigeon[2]. To achieve this the pectoral musc would have had to be even more powerful than t pigeon's, but it is clear from the anatomical eviden that they were not.

In every aspect of flight it seems that *Archaeopter* was inferior to modern birds. Calculations on the strengt of the humeri of some pterosaurs and other fossil bi have led to similar conclusions. These will be discuss elsewhere[11].

Book Reviews

PLEASURES OF RESEARCH

First and Last Experiments in Muscle Mechanics

By A. V. Hill. Pp. xv+141. (Cambridge University: London, May 1970.) 55*s*.

It was a pleasure to read this book by Professor Hill, not only because it provides an excellent up to date review of the subject of the mechanics of muscle, but also, and perhaps chiefly, because the pleasure which the author took in writing it shines through so clearly in every chapter. In his years of retirement he looks back over everything he has done on this special aspect of muscle physiology during his long career. He traces the development of the various theories and notes where he went wrong and why. He shows where the work of others caused some revision in his thinking and he very generously gives credit, sometimes perhaps too much credit, where he feels it is due to others. He takes the reader through what he calls "the bad old days of the visco-elastic theory" and shows why the theory needed modification. Actually it was not a bad theory and served very well for many years, but the author did not hesitate to discard it in the light of new evidence as it appeared. For one who at one time worked in Professor Hill's laboratory and who participated to a small extent many years ago in some of the work described, the book is fascinating reading and a fine example of the power of simple but meticulous experiments coupled with sagacious and sophisticated interpretation.

The first experiments by Gasser and Hill in 1923, with nothing more than a simple lever and a smoked drum, were as original and bold in concept as any in the book and they differed from the "last" experiments chiefly in the type of recording equipment available at the time. The book ends with a speech made by its author at the International Congress of Physiological Sciences held in Tokyo in 1965 when he was given the keys of the city by his former student, the governor of Tokyo, Ryotaro Azuma. He certainly enjoyed that occasion, but mentions that it interrupted his "last" experiments. Even after that gala occasion he was eager to get back to the laboratory to put the finishing touches to his work on the mechanics of muscle.

One does not get the impression from this book, however, that the subject is now closed. Rather the book indicates many places where more work is needed. One chapter, for example, ends with the plea: "Will someone please make the experiment in this way ?". At another point he asks for better time records of delayed isometric contractions in single fibres without an external series elastic component (s.e.c.): "Then we could answer the question at the head of this chapter", that is, "How much of the s.e.c. can be accounted for within the sarcomere ?".

The book makes particularly clear that a muscle is a population of many fibres differing greatly in their velocities of shortening and in their response times. Indeed, the book might have been entitled a reappraisal of muscle mechanics in terms of the statistical distribution of fast and slow fibres, for this explains many of the anomalous records obtained. Similarly, the differing population of sarcomeres within a single fibre is considered, because the stronger units stretch the weaker ones, thus modifying the rate of development of tension externally.

Another complication, clearly recognized by Hill, is the fact that the excited state does not develop instantaneously at the moment of stimulation, nor at the same speed in all fibres. To avoid this, many experiments had to be carried out with "delayed isometric contractions" when the muscle is stimulated so that it would shorten a bit before reaching the length desired for recording. With this procedure the excited state is fully developed when the important part of the record begins, thus eliminating one complicating factor.

One interesting new fact in the book is the observation that "a preliminary high tension makes the series elastic component (s.e.c.) less extensible, but the greater stiffness rapidly passes off under low tension". With regard to this odd finding Hill remarks with characteristic humour, "There are more things in heaven and earth, Horatio—and even in frog muscles". True, but it takes a keen mind or an A. V. Hill to discover them. Many such "things" are described in this book. They are all in a sense trivial, but they add up to provide a penetrating view of muscle mechanics which is by no means as simple as it sounds.

Professor Hill's many contributions to this subject will always be remembered as "classics". It is only to be regretted that he is no longer active in the laboratory where he inspired so many younger physiologists by his approach to research, which was fundamentally so serious but outwardly rather gay and humorous. He thoroughly enjoyed his work and so did his students. This book accurately reflects the stimulating atmosphere of his laboratory.

Wallace O. Fenn

INTRODUCTION TO LIFE

The Life Process

By J. A. V. Butler. Pp. 256+12 plates. (Allen and Unwin: London, August 1970.) 60*s* boards; 35*s* paper.

This book is in the same style as its two predecessors by the same author, *Inside the Living Cell* and *The Life of the Cell*. It is intended as a relatively elementary book for students beginning university studies and is probably set at about the right level to achieve this aim. Like its predecessors it covers a wide range from the chemistry of proteins and DNA, on the one hand, to the function of the brain and ageing on the other. Professor Butler has a knack for couching complicated facts in simple language and he manages to present a large amount of information in digestible form. But, perhaps inevitably, the book is patchy. Some parts are extremely well done, especially the chapters on molecular biology, that is, those on DNA and replication, the genetic code, viruses, the genetics of bacteria and viruses, and regulatory mechanisms of bacteria. These are quite detailed and yet easy to read. On the other hand, the chapter on the hormones provides little more than a list of known hormones. Those in sense organs, cell membranes, nerves and brain also receive superficial treatment. Because textbooks abound

on each of these topics, it is not easy to see what useful information could be crammed into chapters of five to ten pages in an elementary textbook. Perhaps it might have been better to limit its scope. Apart from this shortcoming the book provides a readable and up to date introductory text.

An interesting feature of Butler's style is that he is meticulous in mentioning the names of the scientists associated with each discovery. The book is well illustrated with clear line drawings and plates of moderate quality. It has a well-selected bibliography for each chapter.

JOHN PAUL

SCAVENGING CELLS

The Macrophage

By Nancy N. Pearsall and Russell Weiser. Pp. x+204. (Lea and Febiger: Philadelphia, 1970. Distributed in Great Britain by Henry Kimpton, London.) 76*s*.

IT is impossible in a short review to do justice, critically and otherwise, to this little book in which the authors have compressed an enormous amount of information, in fact, more than it can hold, and under chapter headings which frequently indicate overlap.

Although the book is called *The Macrophage*, great emphasis is laid on the diversity of macrophage populations and the great inter- and intra-species differences that exist among these populations morphologically, biochemically and functionally. Strangely, the fact that cultured fowl macrophages proliferate actively in homologous serum is not mentioned; yet the special macrophage growth factors necessary for the proliferation of macrophages ("mammalian" should have been added) receive due consideration.

In the first half of the book, the structure of macrophage (poorly illustrated by only a few electron micrographs), phylogenetic and ontogenetic aspects, sources and lifespan, cellular interrelationships (incidentally, the claim that lymphocytes transform into macrophages only in the presence of polymorphs still awaits confirmation), metabolic activities, phagocytosis and functions (sic!) of macrophages are reviewed and discussed. The chapter on metabolism contains a useful, comprehensive table on enzymes found in macrophages.

The second half of the book is concerned with the role of macrophages in immunological situations and is addressed more to the expert in this field than to the uninitiated reader. It deals with contributions of macrophages to the antibody response, with antibodies cytophilic for macrophages, with delayed sensitivity and antitissue and antimicrobial cellular immunity with special discussions of tuberculosis, leprosy, the *Listeria* and the *Salmonella* systems. There is no doubt that macrophages act as scavengers, trapping, processing and storing antigenic material, but whether they are specific effector cells remains still an open question; and it is perhaps significant that one of the authors' concluding sentences reads: "Overall, lymphocytes and macrophages cooperate in an effective cellular immune response".

The great merit of the book lies in the accumulation of numerous data on the subject which have appeared in recent years in widely scattered journals. Of the 699 references quoted, only 160 were published before 1960; this makes the work invaluable as a reference book. One can say, it is up to date as far as this is possible these days. Some of the papers quoted are reviewed in detail; others are summarized in such a condensed form that this does not give sufficient information or sometimes even a misleading or an inaccurate one; and any reader of this monograph would be well advised to go back to the original reference, because this is, after all, one of the aims of this book.

F. JACOBY

BEFORE THE ANTIBIOTICS ERA

A History of Medical Bacteriology and Immunology

By W. D. Foster. Pp. xi+232. (Heinemann (Medica London, July 1970.) 40*s*.

THERE is a wide variety of general books on the history medicine but, on the whole, the history of its special are is less well served. Thus this book is only the third histo of bacteriology in English to appear and the need for has been evident for some time because neither of i predecessors, Bulloch's *History of Bacteriology* (1938) a Ford's *Bacteriology* (1939), is entirely adequate. Bulloc for example, dealt at great length with the earlier perioc finishing at 1900, and did not cover the medical aspects the subject fully.

Dr Foster is ideally suited for the task of providing competitor for Bulloch and Ford because he has alreac published excellent accounts of the history of clinic pathology and of parasitology. He begins his book with brief introduction to the germ theory of disease which w established in the 1870s, and then discusses in detail tl contributions of Pasteur and Koch to its foundatio There is a good chapter on the discovery of the mo important human pathogenic bacteria, a vital aspect of tl subject but hardly mentioned by Bulloch. As his tit indicates, Foster includes the history of immunology, fir its scientific basis and then its practical application medicine; in this regard he might have mentioned *History of Immunization* by H. J. Parrish (1965). The la two chapters comprise an excellent account of the princip developments in bacteriology during the early twentiet century, and in the chemotherapy of bacterial diseas Medical students should be encouraged to peruse thes carefully in order to counter the commonly held view tha specific therapy commenced in the 1930s and 1940s wit the introduction of sulpha drugs and antibiotics. Or useful secondary source Foster omits to cite here is *Tl Impact of the Antibiotics on Medicine and Society* (edite by I. Goldston, New York, 1958).

A criticism of this book could be levelled at the intr ductory chapter dealing with events before the ger theory. From it important men such as Fracastoro, wl gave the first "modern" interpretation of contagio Semmelweis and Oliver Wendell Holmes of puerperal fev fame, and others of merit have been excluded. Admitted Bulloch perhaps discussed early concepts in too gre detail, but Foster would seem to have gone to the oth extreme. It can be argued, however, that, given a limite amount of space, more should be allocated to the mo modern rather than to the earlier period. This may be le acceptable to the historian but it certainly is an advanta to students and practitioners who prefer to know of tl immediate rather than the distant past.

Foster is to be congratulated on his achievement, for l has produced a history of bacteriology which is orientate adequately to medicine and which provides for the fir time an account of the most recent history of the subjec up to 1938, a convenient date because it marks the eve the antibiotics era, as well as the appearance of tl previous histories by Bulloch and Ford. Moreover, he giv evidence throughout of appreciating the meaning an methodology of history. His book can be warmly recon mended and parts of it should be required reading f medical students.

EDWIN CLARKE

TIPS FOR MICE BREEDERS

Methods in Experimental Embryology of the Mouse

By Keen A. Rafferty, jun. Pp. xi+94. (Johns Hopkin Baltimore and London, August 1970.) 81*s*.

WALTER HEAPE, the father of experimental embryology i mammals, wrote: "On the 27th April, 1890, two ova wer

obtained from an Angora doe rabbit which had been fertilized by an Angora buck 32 hours previously.... These ova were immediately transferred into the upper end of the Fallopian tube of a Belgian hare doe rabbit which had been fertilized three hours before by a buck of the same breed as herself.... In due course this Belgian hare doe gave birth to six young—four of these resembled herself and her mate, while two of them were undoubtedly Angoras". Although he tried on many occasions to repeat his earlier feat, it was not till 1897 that Heape achieved two further successful transfers. In the intervening years, he developed the less exacting technique of artificial insemination.

In the early 1950s, when Donald Michie and I began to transfer eggs from one mouse to another, nobody in Britain had used the technique; one worker on the Continent of Europe and two or three in the United States had recently revived the art. Like Heape, we had beginners' luck, but many months of frustration followed. We wrote to L. M. Boot in Amsterdam, the nearest practitioner, who replied with three close-typed pages of excellent advice, and our fortunes improved.

Had Rafferty's book been available at that time, our appeal to Dr Boot might not have been necessary. During the past 15 years, mammalian eggs (most often mouse eggs) have not only been transferred in their tens of thousands, but have been fused together and split apart, cultured *in vitro* and even fertilized *in vitro*, grown in ectopic sites, used for micro-injection experiments and subjected to biochemical analysis and electron microscopy. (Rafferty comments: "One hardly knows where it will all end".). All these techniques and more, together with the equipment which they demand, are described in lucid detail in this book.

Of course the book is not perfect. Rafferty is more successful in his description of techniques than in his accounts of the literature, which are often confused. For instance, it is not true that Billington, Graham and McLaren found that ova "cultured to the blastocyst stage and then transplanted to kidney or testis give much better embryonic development than do blastocysts which developed *in vivo*". The table of normal development, in appendix E, does not emphasize sufficiently that rate of development varies widely from strain to strain. The timing that it gives for blastocyst stages contradicts both my experience and his own Table 1.

Some of the procedures that he describes sound clumsy, and most experienced workers will probably continue to use the methods to which they are accustomed. A day spent in a laboratory where techniques are in constant use is worth many pages of text, however clear. Nonetheless, this book needed to be written and will be widely used.

ANNE MCLAREN

SURVEYS OF HUMAN GENETICS

Modern Trends in Human Genetics

Vol. 1. Edited by Alan E. H. Emery. (Modern Trends Series.) Pp. ix + 379. (Butterworth: London, March 1970.) 95*s*.

AMONG the multi-author publications which plague the scientific literature this is one of those rare exceptions which show unity and little repetition. The editor deserves congratulations for what must have been a tough assignment.

With the exception of the first chapter, the thirteen chapters, all by different authors or pairs of authors, cover most of the areas in which human genetics has made substantial advances recently. Surprisingly omitted are the analysis of autosomal linkage and population genetics. The first chapter, by Boyer, is somewhat out of context. It is, nonetheless, a valuable and stimulating discussion of the various levels at which, in higher organisms, one might expect that regulation of protein synthesis could operate. Hopkinson then summarizes the techniques and the results of the study of enzyme variation—especially electrophoretic variation—in man. The survey carried out in Harris's laboratory at University College, London, reveals the enormous degree of individual enzyme diversity in human populations. Out of eighteen randomly selected enzymes, seven show genetic polymorphism.

Two chapters of great topical interest survey exhaustively two facets of the genetics of the immunological system. One, by Schimke and Kirkpatrick, deals with the genetics of gamma globulin synthesis; the other, by Grove and Bach, with that of leucocyte antigens. How wide can be the range of refinement in genetic analysis is clear in the former: at one extreme, variation is analysed down to amino-acid sequences, for example, in the immunoglobulins; at the other extreme, variation is recognized only at the gross level of organ abnormality, for example, in thymus aplasia. The progress on leucocyte typing—an important tool in transplantation—is well summarized in the second of these two chapters.

Davidson covers the relatively new field of somatic cell cultures as tools in human genetics. The human genetic markers recognizable at the cell culture level so far identified are not far from forty. In addition the number of cellular enzymes known to differ interspecifically, for example, between mouse and man, is increasing rapidly. By using interspecific cell hybridization it has now become possible to identify which human chromosome determines a particular enzyme by finding which chromosome must be present in an interspecific hybrid for the human enzyme to be synthesized. This technique, first successfully applied by Weiss and Green in 1967, has recently led to most interesting developments for the identification of linkages and even of the linear order of human genes.

A chapter by Edwards and Fowler deals with female meiosis and the genetics of human pre-implantation, and their abnormalities, from non-disjunction and abnormal fertilization to errors in cleavage and chimaeras. Meiosis in males with normal or abnormal chromosome complements is treated by Kjessler. Sanger and Race's summary of the present state of mapping of the human *X*-chromosome makes most interesting reading. They conclude by stressing the extraordinary conservatism of the *X*-chromosomes in mammals—no less than five genes, *X*-borne in man, are also so in species ranging from rodents to ungulates.

Four chapters cover some more strictly clinical aspects of human genetics. Emery considers the antenatal diagnosis of genetic disease. In addition to gross chromosomal abnormalities, there are already more than ten conditions which can be diagnosed by culture of amniotic fluid cells or by analysis of the amniotic fluid. This is, of course, of importance in high risk families where early diagnosis can permit prevention (for example, in the case of pyridoxine congenital epilepsy) or termination. Finn gives a very stimulating account of the reasoning which led to the use of anti-Rh immunoglobulin for the prevention of Rh haemolytic disease. The wider implications for the prevention of genetically determined diseases are ably discussed. Wynne-Davies copes with a most difficult field, that of congenital malformations which represent only extreme deviations in a continuous distribution curve. Here the genetical component can only be inferred by comparing the incidence of the malformation among relatives of various degrees. Carter discusses the prospects in genetic counselling and its three purposes: to advise parents at risk on the chance of further affected children; to alert the medical profession on early diagnosis and possibly early treatment and to reduce the incidence of affected children in the population.

Finally, Smith deals with the ascertainment of those at risk in the prevention and treatment of genetic disease. The reduction of infant mortality in Britain has had the dramatic effect of bringing to the forefront the fraction connected with genetic conditions. These now account for

20 per cent of all infant mortality; four times more than at the beginning of the century. Similarly, in adult mortality the genetic component is now relatively greater than in the past. These two facts increase the importance of diagnosis, prevention and, in a small number of cases which will gradually increase, treatment. Carter surveys the various aspects of this increased importance of genetic disease and the formidable ethical problems it raises.

On the whole this very readable book is of interest both to the specialist and to the layman. G. PONTECORVO

BIOLOGY UNDER PRESSURE

High Pressure Effects on Cellular Processes

Edited by A. M. Zimmermann. (Cell Biology: A Series of Monographs.) Pp. xvi + 324. (Academic: New York and London, April 1970). 182*s*; $19.50.

THIS book has thirteen contributors, including the most distinguished recent investigators in the field, several of whom might now be regarded as reaching the peaks of highly productive careers. Each of the eleven chapters is a separate essay, with an extensive bibliography, but together they form a coherent whole, with author and subject indexes. The book is good value; it is packed with information, is well illustrated and is interesting to biochemists, physiologists, microbiologists, protozoologists, embryologists and marine scientists.

F. H. Johnson and H. Eyring, drawing on the theories of Arrhenius and of absolute reaction rates, show how the pressure-temperature relations of bacterial luminescence and muscle tension are probably connected with the volume changes involved in enzyme activity and inactivation. J. V. Landau, with full experimental details, similarly explains the effects of pressure on biosynthesis of protein and nucleic acids, and discusses the possibility that protein synthesis requires the maintenance of a gel matrix, which breaks down under pressure. R. Y. Morita and R. R. Becker, citing dilatometric and other relevant studies on enzymes and aqueous systems, point out the difficulties which arise because the effects of pressure are so various and impossible to control experimentally. T. H. Murakami surveys studies in Japan, covering pressure effects on mitosis, nerve and muscle action, cell permeability, oxygen consumption, enzyme inactivation and protein denaturation. C. E. Zobell broadly reviews effects on the morphology and metabolism of microorganisms.

No bacteria have been found capable of growth at pressures much greater than those in the deep ocean trenches. There are, however, many phyla of marine animals represented at the greatest depths, as H. Flugel and C. Schlieper show, and they report further that the tissues of different shallow-water species are pre-adapted to varying degrees for functioning at abyssal pressures. Some effects of pressure on freshwater heliozoans, suctorians and ciliates are described by J. A. Kitching, who discusses possible mechanisms of response and adaptation. In another chapter on Protozoa, Selma Zimmerman and A. M. Zimmermann show how earlier studies on the division and movement of cells have been extended to ultrastructural and molecular levels. A. M. Zimmermann contributes another shorter chapter, with T. H. Murakami, on the curious cathodal galvanotaxis of *Tetrahymena*, which weakens and eventually reverses if the pressure is increased sufficiently. He goes on to review previous and current research on biosynthesis in the eggs of sea urchins. Finally, D. A. Marsland, to whom the volume is dedicated (on or around his seventieth birthday), adds a particularly well organized chapter about the mechanisms involved in cell division. Knowledge of that has advanced considerably as a result of pressure experiments, but for each question tentatively answered, several new ones have arisen.

E. W. KNIGHT-JONES

DIVERSE MICROBES

The Actinomycetales

The Jena International Symposium on Taxonom September 1968. Edited by H. Prauser. Pp. 439. (Gusta Fischer Verlag: Jena, 1970.) 184*s*.

THIS book consists of papers presented at a symposiu held in September 1968. Although the actinomycet include microbes of economic importance and attract tl attention of a great many workers, a meeting on the sca of this one had not been held for some time. The need f such a publication was therefore considerable.

Treatment of actinomycetes has always reflected tl fact that they have affinities with both bacteria and fun so that there has been a considerable diversityof taxonom theory and method applied to the group, which is w illustrated by this collection of papers. Papers by specialis working on most of the best known genera are include with an understandable emphasis on the most studi *Streptomyces* genus, although it is somewhat surprisi that there is only one paper dealing specifically with t genus *Nocardia*. There is also a section on metho applied in taxonomy which covers techniques such infrared spectrophotometry, cell wall analysis, serolo and numerical taxonomy. The book is concluded by fo papers dealing with taxonomic problems in the Actin mycetales as a whole.

All papers are in English and in spite of occasion inaccuracies the choice of a single language has obvio benefits. Minor misprints are quite frequent and referenc are given in full in most but not all papers. The standa of production of plates and figures is satisfactory. It m confuse some readers to see the name *Actinomyces* used two different senses and it would have been useful to ha an indication in all cases when it was used to descri *Streptomyces* species. There is an index of taxa nam but no author or subject index.

To the specialist and non-specialist alike, this is valuable reference book. The comprehensive range current views and techniques presented provides an acc rate impression of the present state of the taxonomy this group and should serve as a stimulus for future wo Thus frequent discussions on the "importance" of par cular taxonomic characters and the variety of suggest classification schemes illustrate the need for more objecti assessments of character value and the purpose of clas fication schemes. Also, the many new methods providi additional characters may increase confusion if they are r integrated with existing characters in such schemes.

The editor and symposium organizer, Dr H. Prauser, to be congratulated for providing a much needed review this topic. S. T. WILLIAMS

WAR ON WANT

Evaluation of Novel Protein Products

Edited by A. E. Bender, R. Kihlberg, B. Löfqvist a L. Munck. (Proceedings of the International Biologi Programme (IBP) and Wenner-Gren Center Symposi held in Stockholm, September 1968.) (Wenner-G Center International Symposium Series, Vol. 14.) viii + 390. (Pergamon: Oxford and New York, June 197 140*s*; $18.50.

THIS book covers proceedings held two years ago Stockholm. Two years later, the Third Internatio Congress of Food Science and Technology on "Science Survival" in Washington DC again devoted its attent chiefly to "protein problems". A fair comparison therefore be drawn and progress can be measured.

It speaks well for the Stockholm meeting if I state tl no strikingly new approach or discovery was revealed Washington, and anybody reading this well edited b

may, as a listener in Washington, be entitled to say I have read it "all" before, and I mean "all", because this book deals with nutrition and malnutrition seemingly *in toto*.

J. Vogt takes cognizance of the nutrition problems as an economist and discusses the different attitudes expressed in the past two hundred years by men like Quesnay, Malthus and Marx. Few principles expressed are still pertinent today, others have been totally drowned by men with better appreciation of the problem.

J. C. Waterlow describes the protein requirements of men, and is then reminded by S. A. Goldblith how food habits and taboos have often prevented man from using available nutrients. Millions of persons will rather starve than eat food they are not accustomed to and this is a stark reminder to the food scientist trying to make a contribution to overcome world hunger. "You must first reach them, before you can teach them," Goldblith says, and we can only ignore this wise admonition at great peril to our effort.

Looking at the strategy in the evaluation of novel proteins, C. G. King begins by stating that malnutrition reflects a failure of man to adjust to his environment, and corrective measures must embrace not only an understanding of the science of nutrition, but also the essentiality of family planning. This underlines the stark naked truth that no effort, however far reaching, can resolve the world food problem without a measurable successful effort in limiting world population increase.

The second session of the book deals with world protein sources. Nobody seems better qualified than A. M. Altschul to begin this session with a review on oilseed proteins followed by G. Borgstrom's excellent address on fish proteins in all their various forms. New high protein cereal varieties receive a short mention, followed by an evaluation of leaf protein, and the session concludes with a very comprehensive address by L. Enebo on single-cell protein. These newcomers to the field of edible proteins will in time play an important part, and will receive increasing attention.

Nutritional evaluation of proteins by chemical and biological methods follows in session three, giving a much needed up to date picture of a field that has made great strides in the past few years. This valuable reflexion on the science of nutrition is followed gy a look at toxic, hygiene and functional properties of proteins giving the food scientist guidelines, hints and an understanding of this important aspect of food evaluation at a time when legislation in this field is more and more restrictive and embracing. No symposium on food could be complete without stressing the importance of processing and storage on protein quality. In the sixth session a number of well known authors deal with this area of food science competently and comprehensively.

The authors rightly conclude the book with a panel discussion on science and the world food problem, and here scientists who have become household names—while stressing a divergence of views—do not fail to impress on the reader the seriousness of the situation and the need to declare "a war on want" the fight is of global science against global hunger. Who could afford not to read this book ?

A. SPICER

VIRUSES AND PLANTS

Plant Virology

By R. E. F. Matthews. Pp. xv + 778. (Academic: London and New York, May 1970.) 275*s*.

THE rapid expansion of research on plant viruses and virus diseases in the past decade has outrun the few general textbooks available in English. Professor Matthews aimed his book at graduate students, teachers and research workers in virology and allied fields. They will welcome it, within the limitations set by its price, for its many attributes.

The book attempts, and succeeds in large measure, to cover the whole field of plant virology, beginning with assay methods and ending with speculation on the origin and evolution of viruses. One may cavil at the relative length of the sections—60 of its 700 pages devoted to replication and movement seems excessive—but in general the balance seems about right, for it reflects both topical emphasis in research and the fields in which the author has been most active himself.

The style, though often terse, is certainly clear. The author emphasizes his intention: "immunology has been plagued by a complicated and sometimes obscure terminology. Here we will attempt to use a minimum of such words". In defining terms in another context, he carries brevity without lucidity to the extreme: "The term protein shell means protein shell".

I noted some instances of pointless repetition and no doubt missed others. For example, the loss of transmissibility of potato yellow dwarf virus is quoted on pp. 547 and 549. The behaviour of cacao swollen shoot virus in transmission by its mealy bug vector is twice described in the same words on consecutive pages. Extra "polishing" could have shortened the text, although perhaps with little reduction in the price of the book. I noticed few misprints and these did not affect the sense. More serious is the occasional error of fact, such as quoting sudden death of cloves as an example of virus transmission through natural root grafts; the pathogen is a fungus.

The book is lavishly and clearly illustrated. In spite of the author's claim that he went to "some pains in selecting graphs and photographs to illustrate and supplement the text", a little more labour might have produced better examples than some he chose; others, including a full-page portrait of aphids possibly feeding and doing nothing else, would not be missed.

But, on the whole, this is an excellent book which fulfils its purpose and amply justifies the immense work carried out in its compilation.

A. F. POSNETTE

FUNDAMENTALS OF DESALINATION

Reverse Osmosis

By S. Sourirajan. Pp. xix + 580. (Logos, in association with Elek Books: London, August 1970.) 160*s*.

THIS book describes a new process which is developing rapidly. It is concerned primarily with the application of semipermeable membranes to separating water from solutions. This development occurred first because of its potential as a new and economically attractive method of desalination for the supply of potable water. Now its wider scope for separating the components of other aqueous solutions and possibly non-aqueous ones has been realized. The author was directly involved in the discovery of the method of manufacture of special forms of cellulose acetate membrane which formed a basis of this development, and is well fitted to write about the subject of reverse osmosis. He has produced a comprehensive publication dealing with important fundamental aspects and including much useful experimental data.

An introductory chapter deals with historical aspects and outlines the scope of the process. Subsequent chapters deal with the preparation and properties of suitable semipermeable membranes, transport through the membranes, fluid phase mass transfer and process design, the use as a general concentration technique, treating multicomponent mixtures and organic solutions and details of existing engineering designs. These chapters illustrate the much wider scope for the use of reverse osmosis and include appreciably more material than previous publications. Of particular interest is the treatment of stagewise operations to which this process lends itself on a large scale for concentrations and multicomponent separations. The precise mechanism of selective permeation through the

reverse osmosis membranes is not yet clear. The author's preferential sorption theory cannot be considered separately from the repulsion model for electrolyte solutions by Glueckauf and the diffusion models of others. The mass transfer theory correlates small-scale data but has yet to withstand the test of scale-up to large plant because only pilot scale equipment has so far been constructed. Nevertheless, the book is full of well presented informative detail and has brought together extensive information which, up until now, has been scattered through the literature. It can be recommended not only to scientists and engineers for research purposes but also to process and equipment designers who are concerned with the uses of the method for desalination, in the food and chemical industries, and for effluent treatment and other applications.

J. W. CARTER

ORGANIC REACTIONS

The Chemistry of Cyclic Enaminonitriles and *O*-Aminonitriles

By Edward C. Taylor and Alexander McKillop. Pp. xii + 415. (Advances in Organic Chemistry, Vol. 7.) (Wiley (Interscience): New York and London, July 1970.) 280*s*.

THIS book is the seventh volume of an excellent series which one of the authors edits. Whereas the series is chiefly composed of comparatively brief reviews of subjects of wide interest, this volume is devoted to a single subject, and that an esoteric one. Nevertheless, the authors' active interest in the subject over seventeen years has helped them to make a very thorough job of reviewing a field, which is of that kind for which the usual source of information, the indexes of *Chemical Abstracts*, is of little help. This is just the kind of review to present in book form and makes this one excellent value. In design it resembles a superior chapter from *Organic Reactions*, having extensive tables of the known syntheses of enaminonitriles in the first chapter and of *o*-aminonitriles in the second; the word *ortho* in the latter covers all 1-amino-2-cyano aromatic systems and is not restricted to the benzene ring. The first chapter is thus an extensive review of the Thorpe–Ziegler reaction: a persuasive case is made that, although this reaction is well known, it is undeservedly neglected by practising organic chemists. The second, longer, chapter is of more interest to a specialist in heterocyclic chemistry, but it clearly makes a good case for the usefulness of these compounds, and of the reactions used to prepare them, both in heterocyclic synthesis and in the transformations of heterocyclic compounds.

The price is a reflexion of the fact that only libraries will buy copies. They can do so in the full assurance that the book they get is concise, readable and extensive.

IAN FLEMING

PHYSICS OF SEMICONDUCTORS

Lectures on the Electrical Properties of Materials

By L. Solymar and D. Walsh. Pp. xiv + 350. (Clarendon: Oxford; Oxford University: London, August 1970.) 80*s* boards; 40*s* paper.

THE chief purpose of this book would seem to be the development of the physical arguments necessary for an understanding of semiconductor devices. This it does extremely well in nine chapters, starting with the concepts of the electron as a particle and as a wave, introducing Schrödinger's equation and using it to describe the hydrogen atom, bonding, free electron theory and zone theory before discussing semiconductors and devices. Four additional chapters, covering dielectric materials, magnetic materials, masers and lasers, and superconductivity, appear rather as afterthoughts. The treatment is clear, concise and logical, and that of the Ginsberg–Landau phenomenological theory of superconductivity is one of the best I have ever encountered. Non-physicists will have no difficulty in following the arguments as they are developed.

Much material has been omitted which, from the title, one might reasonably expect to be present. There is no discussion of the effect of the structure of real materials on electrical resistivity, dielectric properties, or the irreversible behaviour of magnetic and superconducting materials. To one whose understanding of electronics is extremely limited, the device chapter is the most interesting. Problems of switching speed are, however, neglected: a comparison between the speeds of semiconductor, thin film magnetic (completely ignored), and superconducting switches might have prevented the erroneous statement that the latter are the faster. The implication that lasers are a solution without a problem will please at least one of my colleagues.

The style is chatty and condescending; the many sneers directed at physicists ("honest engineers" obviously implies "devious physicists") do nothing to heal the unfortunate breach between the two professions. The treatment is uneven; an acquaintance with advanced mathematical techniques, such as Fourier transforms, is assumed while many simple physical concepts are laboured or dismissed as being too difficult.

As described in the preface, the book is very obviously an almost verbatim account of a lecture course given by the authors to second-year undergraduate engineers at Oxford and herein lies the source of the weaknesses criticized earlier. Careful editing could have produced an extremely valuable and self-sufficient textbook. As it stands, the book is unlikely to be used as a course text (most lecturers use an informal style similar to that of this book, and require the backing of a more authoritatively written text) but can be highly recommended for additional reading. The authors at least are to be commended for submitting their manuscript to a British publisher, thus ensuring that the price is still within the reach of some pockets.

DAVID DEW-HUGHES

FINDING EIGENVALUES

Latent Roots and Latent Vectors

By S. J. Hammarling. Pp. x + 172. (Hilger: London 1970.) 100*s*.

As the publishers say on the dust-cover of this book, latent roots, characteristic values, eigenvalues—call them what you will—are of fundamental interest in almost any field of study to which mathematics has been applied. For the mathematician there is Dr Wilkinson's authoritative treatise to refer to, but that work lacks the simple numerical examples which the engineer, physicist or economist needs before he can understand the many and various methods of finding eigenvalues and their associated eigenvectors and appreciate to which type of problem each is most applicable.

In this book, after two chapters in which basic theorems are proved and some applications presented, a separate chapter is devoted to each of the better known methods: Danilevsky, Givens, Householder, Krylov and Lanczos. Iterative methods and, in particular, the Q–R algorithm are described. Each method is illustrated by simple but not trivial examples and there are a number of well chosen exercises to consolidate understanding. A final chapter summarizes some other methods and indicates the reasons why they are not so popular.

This book gives an introduction to the problem of finding eigenvalues pitched at just the right level for the non-mathematician, but I am afraid that its price may prevent it being read as widely as it deserves.

A. H. CRAVEN

Correspondence

Apartheid for Whom ?

SIR,—Your review (*Nature*, **227**, 5; 1970) of my two papers in the *South African Journal of Science* (**65**, 329; 1969, and **66**, 12; 1970) gives a false impression both as to the extent of duplication of research in South Africa and its cause. The question asked in the survey was, "Have you ever had the experience of discovering after you had completed a piece of research that someone else had already discovered and published substantially the same facts ?". Although 17·5 per cent of the responses were affirmative, one is not justified in concluding that "nearly one South African scientist in five is duplicating research being carried out in other laboratories", or that this is a "feature of the isolation of South Africa". It is interesting to note that my figure for South African research workers is remarkably close to those obtained in similar surveys by Martyn[1] and Flowers[2] in the UK, Törnudd[3] in Scandinavia and Glass and Norwood[4] in the USA. Likewise the reasons for the failure of scientists to learn of other work in their fields in time to avoid duplication of research are much the same in those countries and are related rather to the literature searching habits of the scientists themselves than the political systems under which they work, as seems to be implied in your choice of headline.

Owing to a delay in the publication of my paper by the *S.A. Journal of Science*, the figures for the remuneration of research scientists are grossly out of date. I am happy to be able to report that currently the financial rewards of scientific research in South Africa are some 15 to 20 per cent better than those listed for various groups in my paper.

Yours faithfully,
D. RYLE MASSON

CSIR Natal Regional Laboratories,
Post Office Box 1, Congella,
Durban, South Africa.

Phytopathology in Brazil

SIR,—I read with great interest the short report on the occurrence of coffee rust in Brazil (*Nature*, **226**, 997; 1970). I was also interested in the fact that many of the author's conclusions were based on observations made by Professor F. L. Wellman on the occasion of his recent visit to the rust-infected area.

I have known Professor Wellman for many years and also met him during his recent visit to Brazil, so I am sure he would be the first to agree with me about the need to add more details to the report and to give credit to a larger number of phytopathologists. He did not fail to give generous credit to others in another recent report[1].

The occurrence of the disease was observed by Brazilian phytopathologists, who also made a correct diagnosis of the causal agent. This diagnosis was later confirmed by other Brazilian colleagues. Among the Brazilian phytopathologists concerned with the problem I should mention Mr Arnaldo Gomes Medeiros (Centro de Pesquisas do Cacáo, Itabuna), Dr A. A. Bitancourt, and Miss Victoria Rossetti (Instituto Biológico, São Paulo) and Professor Charles F. Robbs (Universidade Federal Rural, Rio de Janeiro).

There is a relatively large number of phytopathologists working in Brazil, and they joined a few years ago to form the Brazilian Society of Phytopathology (Sociedade Brasileira de Fitopatologia.) In this connexion it should be mentioned that the first foreign phytopathologist approached by the Brazilian authorities to take part in the planning of control measures was Professor A. Branquinho D'Oliveira (Centro de Pesquisas sôbre ferrugem do Café, Oeiras, Lisbôa, Portugal). Some phytopathologists from other countries, such as Dr E. Schieber from Guatemala, were also given the opportunity to study the problem *in loco*.

Yours faithfully,
KARL M. SILBERSCHMIDT

Instituto Biológico,
Caixa Postal 7119,
São Paulo, Brazil.

The Definition of Aggression

SIR,—In his article in *Nature* (**227**, 1006; 1970) reviewing trends in neuroscience, F. O. Schmitt considers the role which neurophysiological investigations may play in the understanding and control of social behaviour, and of aggression in particular. I do not wish to challenge the methodology nor the interpretation of studies on the implantation of electrodes, etc, nor do I wish here to question the ethics of such research on human subjects. What is of concern, however, is the apparent failure to define the behaviour which is being modified.

Schmitt states, for example, that "violent and aggressive behaviour is an all too prevalent manifestation of social imbalance in many parts of the world", and he later refers to "aggressive and *other aberrant* behaviour" (italics added). It is debatable to what extent any scientist can evaluate or initiate research in the context of the bias inherent in the view that aggressive behaviour is an aberrant form of behaviour and that aggression is too prevalent in the world.

Aggression is a term which can be used to cover a wide variety of forms of behaviour and to be of any value in a scientific context it must be defined in as neutral and precise a manner as possible. Any investigation of social behaviour has to identify the structure of the behaviour and the structure of the situation in which that behaviour is displayed. It may be that a definition of aggression will include reference to injury or harm to another person, but an analysis of other components in the sequence of behaviour is necessary and account must also be taken of the situation in which the behaviour is manifested. Schmitt's view that aggression is a "manifestation of social imbalance" has prejudged and loosely defined the determinants of the behaviour and has stated an hypothesis in the context of a set of values which prevents rather than facilitates the understanding of the behaviour and its causes. In social science research it seems important to make explicit those value premises which may bias the form of research and the interpretation and utilization of the results of research.

Yours faithfully,
JOHN M. INNES

Department of Psychology,
University of Birmingham.

Theories of Electromagnetism

SIR,—McCaig gives a quite unwarranted impression of confusion in electromagnetism (*Nature*, **227**, 935; 1970). It is not the case that the Kennelly and the Sommerfeld formulations lead to self-contradictory results. McCaig has misinterpreted the basic claims of the two theories. The field of a physical magnet depends on its shape, so the statements that the H-field of a magnetic dipole is inversely proportional to μ_r in the one system, and inde-

pendent of μ_r in the other, are to be understood in reference to a particular shape. The early treatments of magnetism were based on the formulae for isolated poles, so when the same formulae are applied to magnets the shape assumed is that for which the magnet approximates to an ideal dipole, namely bar-shaped. The formulae must then only be used within their range of applicability. (For a magnet which is infinitesimally thin, the field at all points at a finite distance is indistinguishable from the field of a pair of isolated poles.) Kennelly is in this respect an MKS version of the traditional theory of electromagnetism, and his views presuppose the bar shape; Sommerfeld is explicit on the question of shape[1]. Thus it is incorrect to apply the relations uncritically to an ellipsoidal shape.

Both the traditional and the Sommerfeld systems are self-consistent, in magnetic media as well as vacuum. The two theories, however, make different statements about observable results; therefore they are not both consistent with the facts. The difference between them is of fact, not of arbitrary convention. The difference is not shown simply in the position of μ_r, for this difference can be accommodated by a different interpretation of magnetic moment. The difference in factual content comes when one asserts what magnetic quantities are constant. I gave the references previously[2].

An experiment has been performed[3], which decided in favour of the traditional view, and against the view now associated with the name of Sommerfeld; but it was not satisfactory and should be repeated. But in the meanwhile one can readily show that the factual falsity of Sommerfeld follows from the basic equations of magnetostatics, namely, div $\mathbf{B}=0$, curl $\mathbf{H}=0$, $\mathbf{B}=(\mathbf{H}+\mathbf{M})/\mu_0$, if one supposes that an ideal "hard" magnet is one in which magnetization $\mathbf{M}$ is unchanging. I propose publishing a fuller discussion on another occasion.

The clear understanding of electromagnetism is difficult; it is therefore important to eliminate mistakes as quickly as possible.

Yours faithfully,

H. V. Stopes-Roe

Department of Extra-mural Studies,
University of Birmingham.

Disputed Pronoun

Sir,—It is simple to make the disputed sentence make sense by re-arranging the clauses in their syntactical order of importance—a sequence used by every competent journalist in this country. Thus: "John was surprised to learn (that) he had won the race." Mis-related participles are unacceptable because of their lack of precision.

I must confess surprise that the medical and scientific communities, who put so much stress on publication, are unaware of this basic rule, which is, I admit, related in practice to the degree of concentration available for sentence construction.

What does genuinely worry me is that people who can not set down their thoughts clearly may not be capable of thus assembling them. I trust, to preserve our belief in the omniscience of the communities concerned, I am forthwith proved wrong.

Yours faithfully,

Alistair Campsie

Highfield East,
Bridge of Allan,
Scotland.

Obituary

Professor W. O. Kermack

William Ogilvy Kermack, who died on July 20, 1970, made distinguished contributions to chemistry, biochemistry and statistics. He was born in Kirriemuir, Angus, on April 26, 1898, attended Webster's Seminary, Kirriemuir, and graduated at the University of Aberdeen in 1918. The following year he joined Professor W. H. Perkin, jun., at the Dyson Perrins Laboratory, Oxford, and succeeded in synthesizing heterocyclic compounds related to the alkaloid harmaline. In 1921 he became head of the chemical research laboratory, Royal College of Physicians, Edinburgh, but a laboratory accident in June 1924 rendered him totally blind. Such a catastrophe, which would have ended most research careers, presented a challenge to him to seek a way of resuming his scientific life. This he was able to achieve by the careful design of experiments which were undertaken by others under his direction. He kept abreast of the literature by having selected articles read to him, sometimes by colleagues, but especially by his wife without whose help he could not have continued. By 1930, in addition to his work in synthetic organic chemistry, he had studied the mechanism of flocculation of colloidal solutions and investigated certain aspects of glyconeogenesis.

After 1930, his organic chemical interests led him to look for new antimalarials. Many new quinoline and acridine derivatives were synthesized and, later, some substituted pyridoacridines and phenanthrolines, a few of which had great chemotherapeutic potency. The decade 1930–1940 was also the period of his greatest activity in the sphere of medical statistics, where he made important contributions to the mathematical theory of epidemics. At the same time, he began to write review articles on recent advances in biochemistry. Over a period of twenty years, few aspects escaped his notice. In 1938, he collaborated with Dr Philip Eggleton in writing *The Stuff We're Made Of*. This layman's guide to the basic sciences on which biochemistry is founded is still an entertaining book.

In 1949 he was appointed to the Macleod Smith chair of biological chemistry in the University of Aberdeen and characteristically accepted the task of creating a new department. His teaching commitments, University administrative duties, committee work in connexion with local research institutes, and plans for a School of Biochemistry left little time for research, yet he managed to study several biochemical problems principally concerned with amino-acids and enzymology. By the time of his retirement in 1968, he had established an active and effective department of high reputation.

During his career, many honours came his way, including Fellowship of the Royal Society of Edinburgh (1924), honorary LlD of St Andrews University (1937) and Fellowship of the Royal Society (1944). His scientific knowledge was broadly based and the clarity of his thinking, the logic of his arguments and his understanding of first principles were widely acknowledged. His advice was always generously given to colleagues who brought their problems to him. He enjoyed discussion within a small group, and had a good memory for scientific anecdotes and a sense of fun. His achievements would have been remarkable for anyone, but for a man blinded so early in life they could well be unique.

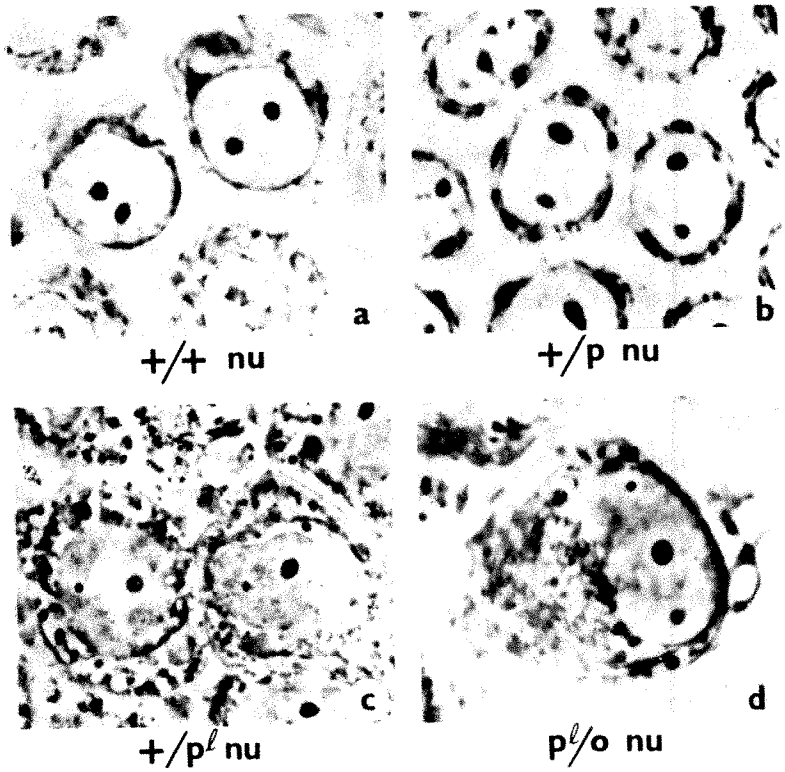

Fig. 1. Phase contrast preparations of epithelial cells from tadpoles having (*a*) two equal nucleoli (*+/+ nu*); (*b*) two slightly unequal nucleoli (*+/p nu*); (*c*) two very unequal nucleoli (*+/p^l nu*); and (*d*) one nucleolus and two extra nucleolus-like bodies (*p^l/0 nu*). *a* and *b* are from tentacles of stage 56 tadpoles, while *c* and *d* are from the tail tips of stage 42 tadpoles.

ERRATUM. Fig. 1 was unfortunately omitted from the paper "Mutations affecting the Size of the Nucleolus in *Xenopus laevis*" by Leo Miller and J. B. Gurdon (*Nature*, **227**, 1108; 1970). Under the subheading "Development of *p nu* Mutants", the third and fourth sentences should read: "The *p/0 nu* embryos, with a single large nucleolus in each cell, develop and metamorphose normally. In contrast, *p^l/0 nu* embryos, which contain extra nucleolus-like bodies in addition to a large nucleolus in some of their cells, die as tadpoles before starting to feed".

Announcements

University News

Mr P. E. Doak has been appointed to the Hawker Siddeley chair of theoretical acoustics in the **University of Southampton.**

Dr A. R. Lansdown has been appointed director of the Tribology Centre, **University College of Swansea,** in succession to Professor F. T. Barwell.

Appointments

Dr K. E. Scheer, University of Heidelberg, has been appointed director of the Division of Life Sciences in the Department of Research and Isotopes, **International Atomic Energy Agency.**

Dr Gordon K. Moe, director of research at the Masonic Medical Research Laboratory, Utica, New York, has been appointed to the National Advisory Heart and Lung Council of the **US National Heart and Lung Institute.**

Professor A. J. Cole, University of St Andrews, has been elected chairman of the **Inter-University Committee on Computing.** The committee reports to the Vice-chancellors and Principals Committee on matters of policy concerning the teaching of computer science and the development of computer services.

Mr H. J. Habakkuk, University of Oxford, **Professor J. B. Jepson,** Middlesex Hospital Medical School, and **Mr D. T. Richnell,** University of London, have been appointed to the **Advisory Committee for Scientific and Technical Information,** under the chairmanship of **Dr L. Rotherham.**

Miscellaneous

The Presidium of the Academy of the Sciences of the USSR has awarded the **I. I. Mechnikov gold medal for 1970** to **Boris L'vovich Astaurov** for his work in experimental genetics.

The European headquarters of the **Stanford Research Institute** has been established in London, and **Dr Torben Meisling** has been appointed managing director of SRI–Europe.

The first congress of the **European Association for Cancer Research** was held in Brussels last month. Membership of the association is open to individuals who are, or have been, engaged in either clinical or experimental cancer research. Further information can be obtained from the secretary, Dr G. J. V. Swaen, Wilhelmina Gasthuis, Amsterdam, Holland.

Price of Nature

From this week, the price of *Nature*, which has been unchanged since January 1963, will be increased from 4*s* to 5*s* for those who buy the journal through newsagents or who buy single copies. The subscription price of the journal will remain unchanged. The present increase, which will apply to some ten per cent of the weekly production of *Nature*, is made necessary by the increased cost of printing.

British Diary

Monday, October 12

Cytology of the Living Vocal Cords (5.30 p.m.) Dr Renato Segre, University of London, at the Institute of Laryngology and Otology, 330–6 Grays Inn Road, London WC1.

Jacking of Railway Bridge Abutments (5.30 p.m. informal discussion) Institution of Civil Engineers, at Great George Street, London SW1.

Tuesday, October 13

Driers (7 p.m.) Mr J. Turner, Oil and Colour Chemists' Association, at the Pendragon Hotel, Clarence Parade, Southsea, Hants.

Industrial Reciprocating and Rotary Compressors: Design and Operational Problems (three-day conference) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

Medical Education in the United States, 1870–1970 (5 p.m.) Dr John Field, University of London, at St Mary's Hospital Medical School, Wright Fleming Institute Lecture Theatre, Norfolk Place, London W2.

Radiological Safety Aspects of Nuclear Power Stations (10 a.m.) Society for Radiological Protection, at London.

Some New Applications of Atomic-absorption Spectroscopy in the Metal Industry (7.15 p.m.) Mr P. Davy, Mr W. W. Fletcher and Mr E. Waugh, Society for Analytical Chemistry, Atomic Spectroscopy Group, jointly with the Modern Methods of Analysis Group of the Sheffield Metallurgical and Engineering Association, at BISRA Group Laboratories, Hoyle Street, Sheffield.

The Idea of a University (1.20 p.m.) Professor Richard Wollheim, University of London, in the Botany Theatre, University College London, Gower Street, London WC1.

Traffic Engineering (7 p.m.) Mr T. D. Hobbs, Society of Environmental Engineers, at the University of Birmingham.

Wednesday, October 14

Aircraft and the Bird Hazard (6 p.m.) Mr G. W. Underwood, Society of Environmental Engineers, in the Mechanical Engineering Department, Imperial College, Exhibition Road, London SW7.

Cellular Growth, The Role of Hormones and Nutrition (5.30 p.m.) Professor Donald Cheek, University of London, at the Institute of Child Health, 30 Guilford Street, London WC1.

Rheology and Processibility of Printing Inks (7 p.m.) Mr C. O. Rosted, Oil and Colour Chemists' Association, at the Borough Polytechnic, Borough Road, London SE1.

Some Aspects of Paint Formulation (4.30 p.m.) Mr T. W. Wilkinson, Oil and Colour Chemists' Association, at the Manchester Literary and Philosophical Society, 36 George Street, Manchester 1. (Student Lecture.)

Whither Fats in Animal Feeds (6.15 p.m.) Dr L. G. Chubb, Society of Chemical Industry, Food Group—Nutrition Panel, at 14 Belgrave Square, London SW1.

Thursday, October 15

Food from the Means—is the Future Really Promising? (1.20 p.m.) Dr I. Morris, University of London, in the Botany Theatre, University College London, Gower Street, London WC1.

Problems of Sludge Treatment and Disposal (5.30 p.m. informal discussion) Institution of Civil Engineers, at Great George Street, London SW1.

Some Aspects of Coil Coating (6 p.m.) Mr J. Hortensius, Oil and Colour Chemists' Association, at the St Enoch Hotel, Glasgow.

Some Botanists of South and South East Asia (5 p.m.) Dr J. C. Marr, Linnean Society of London, jointly with the Royal Asiatic Society, at Burlington House, Piccadilly, London W1.

The NPL Mekometer and Its Application to Mine Surveying and Rock Mechanics, Mr C. M. St John and Dr T. L. Thomas; **The Hathern Anhydrite Series, Lower Corboniferous, Leicestershire, England,** Dr P. G. Llewellyn and Dr R. Stabbins; **The Hamersley Iron Pellet Plant,** Mr J. R. Hammond, (5 p.m.) Institution of Mining and Metallurgy, at the Geological Society, Burlington House, Piccadilly, London W1.

The Storage and Stability of Radiochemicals (6.30 p.m.) Dr Catch, Society for Analytical Chemistry, Radiochemical Methods Group, at the Leicester Lounge, Glasshouse Street, London W1.

What are Patents Anyway (5.50 p.m.) Mr Kingsley M. Wray, Society of Chemical Industry, Road and Building Materials Group, at 14 Belgrave Square, London SW1.

Friday, October 16

Engineering Aspects of Rock Weathering with Examples from the Dartmoor Area (5 p.m.) Mr P. G. Fookes, Mr W. R. Dearman and Mr J. F. Franklin, Geological Society, Engineering Group, at Burlington House, Piccadilly, London W1.

Polymer Developments—The Seventies and Beyond (6.30 p.m.) Mr G. L. Holbrow, Oil and Colour Chemists' Association, at the Chamber of Commerce House, 75 Harborne Road, Birmingham 15.

Saturday, October 17

Water and Plant Life (10 a.m. conference) Joint Biology Committee, in the William Beveridge Hall, University of London, Senate House, Malet Street, London WC1.

Monday, October 19

Development of Immersed Tunnelling in Eurpoe (5.30 p.m.) Mr Alex Christiani, Institution of Civil Engineers, at Great George Street, London SW1.

Karl Marx and the Withering Away of Social Science (5.30 p.m.) Mr G. Cohen, British Society for the Philosophy of Science, in the Joint Staff Common Room, University College London, Gower Street, London WC1.

Physiological and Clinical Results from Cardiac Pacing (4 p.m.) Dr Edgar Sowton, University of London, at the Royal Postgraduate Medical School, Du Cane Road, London W12.

The Work of the ALRC (2.15 p.m.) Dr P. T. Haskell and Mr R. D. MacCuaig, Society of Chemical Industry, Pesticides Group, at the Anti-Locust Research Centre, College House, Wrights Lane, London W8.

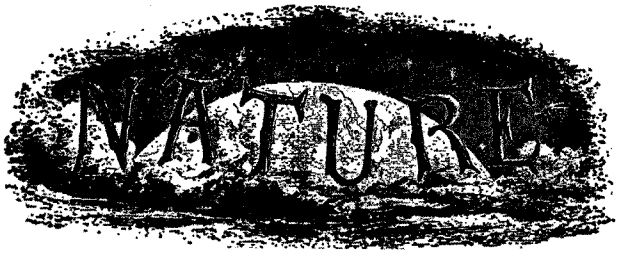
We Are All Luddites Now

TACTICALLY, the new British Government's proposals for trade union legislation have been a minor masterstroke. For one thing, they have acutely embarrassed the Labour opposition by stealing many of the proposals for legislation which the old Labour government first urged on the House of Commons but then withdrew in the face of opposition from the trade unions. Second, they are at first sight a judicious mixture of restraint on employers and employees, even though everybody must know that the balance of advantage will depend entirely on how the proposed system for regulating disputes functions in real life. Third, the new proposals have been introduced at a time when Britain seems likely to be plagued by a rash of industrial disputes in industries as different as coal mining, refuse collection and motor car assembly. Evidently the government will only win friends for itself by seeming to grasp the nettle of industrial disputes at this stage in the economic history of Britain, and this is undoubtedly just. Some regulation of this kind is no doubt necessary. Even if employers and employees have conflicts of interest, there is no reason why these should not be resolved within the compass of a legislative framework. But this is only half the battle and the more immediate half. The question which neither the government nor the opposition has tackled is that of providing a pattern for labour relations decades from now, when there is a danger that many of the jobs on which people's livelihoods at present depend may have become fossilized survivals from the past.

One sign of the way the wind is blowing can be seen easily enough in the pattern of the industries in which there have recently been labour troubles. Garbage collectors, and the army of low paid workers who work for the local authorities in Britain, are unfashionably employed. Nobody loves them, they are badly paid and they are denied even the glamour of technology. Nobody should be surprised that people trying to keep families alive on basic wages of less than $2,000 a year should now be up in arms. Unhappily, however, there is very little chance that their just demands on society could be satisfied without their jobs being priced out of the market. Local councils are prepared to pay garbage collectors less than a seemly wage for demeaning work, but would quickly install machines instead if the going rate were several times as much. And the same is true even in technically advanced industries such as motor car assembly. Here, too, the chief difficulty is that the jobs that are being carried out resentfully are jobs in the twilight that exists between work for human hands and work for machines. The higher the rates for which the motor assembly unions settle the more rapid will be the conversion to machines. What those now grappling with trade union legislation should appreciate is that the time will come when unfashionable jobs are entirely out of fashion. What will labour relations be like then?

What are the goals at which to aim? And if technology will change the pattern of employment in the years ahead, does it also suggest how industrialized societies should adapt to change? In the flurry of excitement about what is sometimes called technological forecasting, there has been too little attention to side-effects like these. In basic industries such as coal mining, however—one of those in which labour troubles seem unavoidable—it should be possible to make quite precise calculations of the effects of technical development.



Ten years ago, 500,000 miners were able to produce close on 200 million tons of coal a year, but it was also clear that wages accounted for such a large proportion of the total cost of coal production that coal would price itself out of the market if there were not a rapid improvement of the productivity of miners—another way of saying that mechanization had become essential for the survival of the industry in competition with petroleum. In the event, there has been a dramatic improvement of the efficiency with which coal is extracted from British mines, but this has not been dramatic enough entirely to cancel out the rising cost of labour, which is quite properly linked with the prosperity of the country as a whole. Moreover, it now seems that the improvements of efficiency which marked the sixties are coming to an end (although this is a point on which the National Coal Board should have more to say). The result is that coal is moving rapidly into a situation in which miners feel hard done by, in which coal is, in any case, uncompetitive and in which even the most optimistic supporters of the industry can only look forward to a further decline of output. In circumstances like these, nobody should be surprised that the miners are up in arms. The best strategy for the National Coal Board to follow would be to abandon the concept that coal can still be an important source of power in Britain (which would also imply an abandonment of the tax penalties to which oil-burning power stations are subjected) and a determination to sell coal for chemical purposes (as in iron ore reduction) at a price high enough for miners to be paid a decent wage. No doubt there is also a moral in this for the declining industries.

The rash of strikes among the badly paid employees of the local authorities is, for example, reminiscent of the way in which trouble over coal was avoided in the

early sixties. If the local authorities wish, as they should wish, to contain the cost of municipal services, they can only hope to do so by mechanizing demeaning jobs such as the collection of garbage—still one of the most quaint mediaeval survivals in modern British cities. If it is not obvious how the job is to be done, then the local authorities will simply have to spend money on the necessary research.

But will the unions stomach changes of this kind? Perhaps the most serious defect of the government's discussion on paper is that it does nothing to provide the unions with an incentive to act in the best interests of the industries in which they are involved. For the years ahead, this should be the central problem. Out and out syndicalism is not quite inappropriate, but the objectives have something to be said for them.

100 Years Ago

The New Postal Act

AT page 474 Mr. Reeks complains as to the working of the new Postal Act. It seems intended to obliterate the old parcel post. He says, "Herbarium specimens are not excluded." Perhaps so; but they are not included. The provisions of the new Act are limited to books, written and printed matter, genuine trade samples and patterns, so far as regards the two ounces for a halfpenny. All parcels other than books, &c., as described above, go at the letter rate of one penny for each half-ounce.

The postal card is the thin end of the wedge that will hereafter open to us a regular letter rate of a quarter of an ounce for a halfpenny. For instance: we may now send ordinary business communications up to two ounces, thus embodying the matter of twenty postal cards, for the halfpenny, if folded in a paper wrapper. An ordinary business communication of half-ounce weight goes for the halfpenny, if folded as a letter but left unsealed.

I ask, If Government will now take an open letter for a halfpenny, why not take it closed at the same rate? Common sense will hereafter equalise this disparity. The parcel post, however, is at present discontinued. P. N. Row

October 14

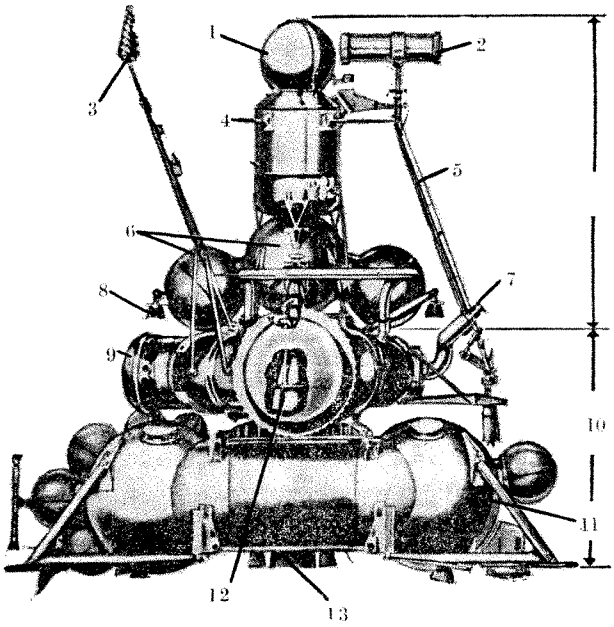
Science and the Government

THE reason that the Government has refused to aid "the expedition to observe the approaching eclipse" is, that it is perfectly assured that "men of science and culture" are nothing but a set of lying impostors, and would swindle the public out of thousands of pounds to take an observation which might be done for 10*l.* and much less. The nation is fast beginning to perceive that astronomy is a monstrous cheat—and the Transit of Venus has no more to do with the distance of the sun than it has with the number of fingers on my hand.

JOHN HAMPDEN

[We congratulate Mr. Lowe on his ally, merely remarking that the same Government which has refused the Eclipse Expedition has granted 20,000*l.* for observations of the Transit of Venus. Perhaps Mr. Hampden can explain the cause of this inconsistency on the part of the Government.—ED.]

From Nature, **2**, 494, *October* 20, 1870.



OLD WORLD

SPACE

Moves towards Cooperation

from a Correspondent

As the annual COSPAR symposium (in spring) gets duller and more specialized, the autumn congress of the International Astronautical Federation (of national rocket societies) becomes more lively. The most productive aspect of last week's meeting at Konstanz, Germany, was the discussion on the standardization of manned spacecraft docking, so that the craft of one nation could come to the rescue of that of another. For the foreseeable future only the United States and the Soviet Union are likely to have manned spacecraft in orbit, and so this amounts to a joint enterprise between the chief space rivals with far reaching implications.

The overall structure of Luna 16 (*Pravda*, No. 227, 1970). 1, Return craft; 2, drilling mechanism; 3, antenna; 4, instrument compartment of the rocket; 5, rod for drilling mechanism; 6, fuel tanks of the rocket; 7, telephotometer; 8, guidance nozzle; 9, instrument compartment of descent stage; 10, descent stage; 11, fuel tank; 12, rocket motor for journey from Moon to Earth; 13, descent stage motor.

The move has been endorsed by a letter from the Soviet Academy of Sciences to the American chairman of the Space Rescue Studies Committee. No Russian delegate attended the previous two meetings of the committee, but this year the leading Soviet space medicine expert Dr O. G. Gasenko took part, accompanied by one of the three Soviet cosmonauts present at the congress, Boris Yegorov. The academy letter undertook that there would be a picked Soviet delegation of four at the next full committee meeting, which will be held at the 1971 congress in Brussels. There is also widespread expectation that bilateral exchanges will be pursued during the visit of four Soviet cosmonauts to the Houston Manned Spacecraft Center in a fortnight's time.

Delegates to the congress also heard detailed accounts

of the rigors of the Apollo 13 mission, when three American astronauts survived by using one compartment of their vehicle as an emergency lifeboat, and of the eighteen day spaceflight by two Soviet cosmonauts in Soyuz 9 last May. Reporting on the Soyuz 9 flight, the ship's captain, Andrian Nikolayev, commented that month-long flights already seemed feasible, but anything longer called for additional and more effective conditioning procedures and new medical treatments. He reported that the post-flight effects lasted much longer than anything encountered on shorter flights. During the first few days both cosmonauts found walking a considerable strain, they were red in the face and they stumbled frequently. It was almost impossible to climb stairs and hard to stand upright. There had been considerable wasting of their lower limbs—as much as 4 cm round the hips and 2 cm in the measurement of the shins. This is attributed to the loss of muscle tissue in the legs, used to supporting the body's full weight at 1 G. Loss of total body weight was about 5 kg for the novice cosmonaut, Sevastianov, and rather less for Nikolayev, but both took about three weeks to recover the loss. This was in contrast to earlier post-flight experience, when lost weight was regained within a day or two. In spite of the weight loss both men felt two to three times heavier than usual for the first few days back on Earth.

In a report on the successful flight of Luna 16 (see illustration), which took place two weeks before the Congress, the deputy director of the Moscow Institute of Space Research, Mr Y. Hodarev, and Mr J. Surkov of the Geochemistry Institute of the Academy of Sciences said little more than the account released last week through the Novosti press agency. Privately, however, the experts revealed that Luna 16 had recovered 200 grams of lunar material, all contained in a single core 35 cm long and 4 cm in diameter. The Soviet members of the congress stressed the role of man in space with as much vigour as the role of automated instruments. There was no sign that NASA intends to revise or review its plans for the remaining four Apollo flights in the light of the new proof of what instruments alone can do.

SEWAGE

River at Risk

THE emphasis during the second week of the strike by British sewage workers shifted suddenly from the exaggerated concern over the danger to human health (*Nature*, **228**, 102; 1970) to justifiable anxiety about the threat to river life. Only two years after the lower reaches of the Thames had become so clean that more than forty species of fish were recorded there, a conservation specialist described the situation as "very serious, if not yet desperate".

Limited stretches of the Thames only have been affected so far, but it has been estimated that 10–20,000 fish may have been destroyed. It will take from three to five years for the rivers to recover completely from the damage caused by the sewage which has poured into them during the past two weeks. Lord Nugent, chairman of the Thames Conservancy Board, said last Sunday that if the strike was settled in a week, normal conditions could be substantially restored by early November. A spokesman for the board said later that as long as the sewage works remained in operation the situation would remain in hand; the staffing problem was getting worse each day, however, and if breakdown or closure of any of the sewage works resulted in further pollution of the river, the threat to river life would be grave.

Toxic substances apart, the presence of sewage in a river makes heavy demands on the amount of oxygen available to the inhabitants of the river. A heavy deposit of sewage on the river-bed requires a great deal of oxygen over a very long period for complete oxidation. Many fish are extremely sensitive to the amount of oxygen in the water in which they live, and cannot survive if the concentration falls below a particular value. Furthermore, the upper reaches of the Thames have, in recent years, become very clear with increasing sewage control, and in consequence the growth of algae and rooted water plants has been much encouraged. Such growth would be sadly cut back in the cloudy and turbid conditions which inevitably follow gross river pollution. Fish and plants will not be the only organisms affected. Invertebrates, such as water fleas and insect larvae, would perish, with disastrous consequences for the short and long term ecological balance of the river.

If the worst comes to the worst it will take a conservatively estimated ten years for the Thames to return to its former healthy state. It is unlikely, however, that the river could again become devoid of life, for fish, insects and plants will quickly return when pollution decreases to a tolerable level. But it would be a pity if the time and money spent during the past ten years in cleaning the Thames were to go to waste for the sake of an extra few thousand pounds on the municipal wage bill.

OCEANOGRAPHY

Mountains under the Mediterranean

from a Correspondent

FRESH information about the geological history of the Mediterranean Basin has been gleaned during the most recent stage of the National Science Foundation's Deep Sea Drilling Project (DSDP). On its voyage through the Mediterranean between August 13 and October 6—leg 13 of the DSDP—the Glomar Challenger collected twenty-seven corings from fourteen sites. Part of NSF's broader National Ocean Sediment Coring Programme, leg 13 was planned by an advisory panel of JOIDES, the Joint Oceanographic Institutions for Deep Earth Sampling.

According to Dr Kenneth J. Hsu, speaking in Paris on October 9, Glomar Challenger's scientific team recovered "long cores of sediments and rocks astonishingly similar to those found in many parts of the Alpine chains of Europe and North Africa". Using these cores it will be possible, for the first time, to compare the nature, age, thickness and sequential relationships of the material of the ocean with those of the surrounding land.

Signs were detected that in at least two places sedimentary formations have been displaced from their original sites of deposition beneath the floor of the Mediterranean. In one case, in the Hellenic Trough, 120 million year old Lower Cretaceous limestones were found immediately above young, soft Pliocene oozes not more than a few million years old. In another place,

north-west of the mouth of the Nile, a huge thickness of abyssal sediments (1–2 million years old), originating in the Nile River, was found upheaved on the submarine Mediterranean Ridge. "These circumstances represent the embryonic stage in a development process," Dr Hsu noted, "which when continued for millions of years will lead to the formation of mountains from the oceanic crust." It seems that Africa and Europe are pressing towards each other and squeezing the Mediterranean sea smaller and smaller, causing parts of the oceanic crust to rise and form mountains.

Glomar Challenger's scientists also found in the Atlantic Ocean samples of the igneous rocks called ophiolites, including gabbros and serpentinites formed at great depths beneath the sea's bed. A large thrust fault seems to have borne these high enough to come within reach of the ship's drill. Just above the ophiolites were Early Cretaceous and Late Jurassic pelagic oozes, the oldest yet to be recovered in the eastern North Atlantic and "strikingly similar" to some recovered 3,000 miles away during leg 11. Discovery of this old sediment, west of Portugal, confirms that the Iberian and African masses broke away from Europe, during one of the first phases of the broadening of the Atlantic, more than 130 million years ago.

Cores from the Mediterranean's three deep basins also yielded dolomites, gypsum anhydrite, diatomites and organic sapropels. According to Dr Hsu, the discovery of an abrupt transition, 5,000,000 years before the present, between evaporites and normal open marine pelagic oozes "marked an abrupt drowning of associated basins through the opening or connexion with the Atlantic Ocean". In the intervening several million years, life has "flourished with very high organic productivities", whereas the eastern Mediterranean's deeper sections were stagnant for several millenia at a time when the enormous ice sheets of the Pleistocene spread and receded. During the same period of about 2 million years "dozens of major volcanic explosions" seem to have occurred in these Mediterranean regions.

CONSERVATIVE PARTY

Mr Davies's Debut

THE Conservative Government's plans for matters technological have at last been spelt out in broad outline by Mr John Davies and others at the Conservative Party conference at Blackpool. In his first and possibly almost last principal speech as head of the Ministry of Technology in its present form, the word denationalization was rather obviously absent and Mr Davies spoke only of private capital "playing its part" in the development and management of already nationalized industries. This is a concept rather different from that feared by Mr Anthony Wedgwood Benn in his sombre warnings to the Labour Party conference the week before. Mr Davies's implication was that there should be no wholesale denationalization but that extra capital should be injected, possibly by the sale of nationalized industry bonds. Could this be symptomatic of a general easing of Conservative policy or is it merely a sop to the more progressive elements?

As far as state aid for private industry is concerned, the cry was very much in favour of help for industries which are temporarily weak, but against any further assistance for those which clearly had no chance of ever regaining strength. This seems to be an economically sane philosophy on the surface, but carries with it the risk of considerable unemployment. The probable fate of the Industrial Reorganization Corporation, which was partially responsible for the merger of British Leyland and BMC, will not please as many people as might be expected. The removal of such an interventionist body ought to be popular, but there is support both among Conservative MPs and throughout industry for the continuation of the corporation in a reduced capacity. Its rapid and complete demise, however, seems inevitable. Casualties among the little neddies—ancillaries of the National Economic Development Council responsible for particular industries—will probably be lighter, and decisions are likely to be taken for reasons that are definitely practical rather than doctrinal. Future plans for the regions were distinctly lacking at the conference although the Conservative Government claims to attach a fair amount of importance to them.

If other proposals for ministry mergers go ahead as planned, it would seem that Mr Peter Walker will eventually be overseer of environment and planning, because his Ministry of Housing and Local Government is likely to expand by swallowing up large parts of the Ministries of Transport and of Public Building and Works. Mr Walker showed good intent by announcing that more green belt would be designated during the lifetime of the present Parliament. Rumours are also flying that the Ministry of Aviation is to be revived under the general eye of Mr Davies.

There is time before the official announcements are made to Parliament for plans to be modified or shelved, but the overall picture must now be considered to be fairly accurate although the details are probably awaited with as much interest as the broad outline.

CERN ACCELERATOR

Two Months to Decide

THE conflicting arguments for and against the construction of a 300 GeV accelerator at CERN are likely to take a firmer shape in the next few weeks, now that the CERN council has officially asked the governments of the member countries to consider the fresh plans for the accelerator (see *Nature*, **226**, 301; 1970). At its meeting on October 8 the council approved the text of the plan prepared by Dr J. B. Adams, the director of the project, and asked the member governments to report back on the documents in time for the council to take a final decision on the project at its next meeting in December.

Three of the four pamphlets which the governments will be considering are concerned with the broad timetable and expenditure involved during the eight year construction programme. The fourth pamphlet is a report on the proposed site for the accelerator, which straddles the French and Swiss frontier near Geneva. One of the attractions of the revised scheme, produced earlier this year, is that the accelerator would latch on to the beam from the 28 GeV accelerator already operating at CERN. Personnel at the 300 GeV machine could also make use of the established support facilities at CERN, although one of the points raised at the recent meeting was whether the increase in the staff for the new accelerator—about a thousand new people are anticipated—could be linked to the building of a European University in the neighbourhood.

The result of borings and investigations of availability suggest that it will be possible to acquire an area large enough to house an accelerator of 2·2 km diameter. This is more than adequate for the revised plan, which envisaged a ring of 1·8 km diameter, but would preclude the option of reverting to the old 1964 design of accelerator if that were ever seriously reconsidered. Discussions are also in progress to arrange for cooling water to be transported from Lake Geneva to the CERN site and for the necessary facilities to draw the vast amount of electric power for the accelerator from the French and Swiss grids.

At the recent meeting the Italian and German delegations expressed concern that the cost of the accelerator should not exceed 1,150 million Swiss francs (£110 million), the amount foreseen in the Adams proposals. Of this about Sfr 250 million is expected to come from economies in the existing installations at CERN. The Italians also stressed the importance of Britain's participation in the new accelerator, which will cost about a third less than the 1964 proposals which the previous British Government found too expensive.

COMPUTERS

Market looks Ahead

IT has been said that the fourth generation of computers may be a long time coming, because the emphasis in the computer world has shifted from the design of bigger and better computers to the efficient use of those currently available or in the pipeline. To a certain extent this has been borne out by Computer 70, an international exhibition held last week at Olympia, London.

Acclaimed as the biggest computer show so far outside the United States, and certainly the most comprehensive in Europe, Computer 70 displayed a vast range of computer peripheral equipment, including countless alphanumeric display terminals and not a few complete computer mailing systems. British manufacturers do not on the whole seem to match up very well to the mainly American competition, and it is widely believed that there are more manufacturers of computer equipment in the northern suburbs of Los Angeles than in the whole of the United Kingdom.

Computers as such were not much in evidence at the exhibition, and the fact that the machines themselves are now taken very much for granted is probably the key to understanding the direction in which computing is heading. Traditional names in the peripheral market, such as IBM and ICL, have now been joined by hundreds more. For several firms, such as Scientific Data Systems Israel Ltd, Computer 70 is their first exhibition appearance. Together these manufacturers seem to cater for the organizational and decorative schemes of any imaginable office. A piece of computer equipment can certainly no longer be called laboratory apparatus, for it has become as basic as an office desk or a typewriter. These may be the first indications that the computer is coming out of the woods as far as society is concerned and is at last becoming almost respectable, in spite of the suspicions of a continuing hard core of opinion.

The general impression created by Computer 70 was underlined by Mr Alex d'Agapeyeff, when he delivered his presidential address to the British Computer Society at its annual dinner last week. Giving his views on the definition of computing and its role in society, he was at pains to make the point that this is no longer a branch of mathematics or physics as it was at one time, but of communications if, indeed, it is possible to classify it at all. He summed up his philosophy neatly by suggesting that computing should now be understood principally as the technology of computer use, with those who follow the profession doing so in a way very similar to the practice of lawyers or engineers.

LABOUR RELATIONS

Upholding Chemists' Rights

THE Royal Institute of Chemistry, one of the largest organizations of its kind, has shouldered the responsibility for negotiating directly with employers the wages and conditions of its 25,000 members. A statement of these plans, issued this week by the institute, comes at a time when graduate scientists are worried that they are being left behind by the progress made by militant trade unions.

The institute has made this change in policy because it is unconvinced of the suitability of trade union policy and tactics for the specific purpose of looking after the interests of professional chemists, particularly those in private industry. The institute claims to have the necessary background of information and experience which the unions lack, and to have better facilities for acquiring it and keeping it up to date. It believes that it should quickly develop the necessary competence to handle negotiations where a most careful appraisal, requiring a thorough understanding of the responsibilities involved, is essential. The institute is also convinced that its high standing in the eyes of the employers will be a valuable asset.

Among the steps that the institute intends to take will be to develop the already considerable records of prevailing salary levels, so that these can be used to provide evidence in actions taken by the institute. In order that individual members may be able to obtain advice locally, regional advisory panels will be established. These panels will recommend action by the institute if they think it is necessary. Arrangements for mediation and arbitration under the supervision of the institute will be made so that disputes between members and their employers can be resolved without expensive litigation.

In no circumstances will the institute call on its members to strike, for it believes that employer and employee should work together to reach agreement rather than act as two opposing factions. That is not to say that the institute considers membership of a trade union to be incompatible with membership of the institute. It is neither hostile to trade unions nor opposed to the principle of collective bargaining. Indeed, collaboration with trade unions and other associations may sometimes be desirable, although the institute says it would prefer to make its own representations on behalf of members. The statement also makes it clear that, in spite of the scheme for amalgamation between the institute and the Chemical Society, the institute will continue to act as a separate and wholly autonomous organization.

The example set by the Royal Institute of Chemistry may well be followed by the other science institutes;

and their greater influence will not merely be of benefit to members. The swing away from science in schools may be checked, and greater incentive provided for students embarking on long industrial training courses.

MEDICINE

Council for Postgraduate Training

THE concern with which both the government and the medical profession regard the training of medical students is reflected in the announcement last week by the Department of Health and Social Security of the establishment of a Council for Postgraduate Education in England and Wales. The new council, whose formation was recommended in the Todd report (Royal Commission on Medical Education, HMSO, 1968), will be chaired by Professor H. N. Robson, vice-chancellor of the University of Sheffield.

The Todd report, after describing postgraduate medical education in this country as "chaotic", laid the blame firmly on a lack of coordination between the universities, the medical profession and the National Health Service. Professor Robson sees the future of the new council as "a channel of communication between the various regional organizations, an advisory body whose decisions will be flexible, but whose efforts will be directed towards ending the present state of free for all in medical training which wastes time and causes needless frustration".

Organizations to be represented on the council include the British Medical Association, the NHS, the Committee of Vice-Chancellors and the various royal colleges of the medical profession. A recently qualified doctor who described his own postgraduate education as "rather disorganized" felt that the new council could do much to improve the situation both for trainee hospital doctors and intending general practitioners.

MEDICAL RESEARCH

New Building for Nuffield Group

THE Nuffield Institute for Medical Research has formally taken over its new laboratories on the University Medical Site, Headington, Oxford. The new building, which was officially opened on October 6 by Sir Geoffrey Gibbs, chairman of the Nuffield Foundation, cost almost £400,000. The building was financed jointly by the Nuffield Foundation and Lord Nuffield's Medical Benefaction to the university, and further funds have been made available from the University Grants Committee to buy furniture and research equipment.

The Nuffield Institute for Medical Research was established in 1935 and was originally housed in the old Radcliffe Observatory in Woodstock Road. The new building, which provides 25,000 square feet of laboratory and office accommodation, represents the first stage in the development scheme; the building is closely linked to the newborn nurseries and the Nuffield Department of Obstetrics in the new maternity hospital alongside, due to be opened next year. The second stage of the scheme should be completed in 1975 with the opening of a new teaching hospital and associated medical school buildings.

From its earliest days the institute has been predominantly concerned with the problems of the developing foetus; these activities will be expanded and developed under the present director, Dr C. S. Dawes, with the aid of a recently announced long term grant from the Medical Research Council.

AGRICULTURAL ENGINEERING

Automation and the Cows

ULTRASONICALLY guided tractors, shakers for harvesting fruit and computers in the milking parlour are some of the innovations on trial at the National Institute of Agricultural Engineering, near Bedford. These and a host of other developments are described in the institute's latest annual report (price £1). The futuristic nature of some of the projects in progress is explained by the director, Mr C. J. Moss, who points out that the work of the institute is not so much concerned with the problems of farming today as with those which will develop from the middle of the next decade onwards.

One of the big problems for farmers in the future is going to be loss of manpower, which puts a premium on the development of automatic methods. An ultrasonic echo ranging device has been used successfully to guide tractors along artificial furrows. The difficulty of using the same method on soil, however, has led to proposals to use optical methods for the same purpose.

Self propelled vibrating equipment has been built for shaking the stems of blackberry bushes. It successfully removed the fruit, and trials are to continue with similar shakers. Harvest by shaking also promises to increase productivity for growers of apples. The damage to fruit caused by shaking the trunks and branches has been found to depend to some extent on the shape of the tree. Both methods, however, were deemed to be promising, and trials have been extended to plum trees.

The liability to damage which such methods could bring may have inspired the testing of resistance to mechanical injury in fruit and vegetables. The relative susceptibilities of conference pears and Cox's orange pippin apples have been investigated by puncturing and compressing them when picked and during storage. The relative hardness of fruit picked early persisted through storage, with the maximum resistance to damage occurring about a week after picking. Compression tests on tomatoes indicated that they could be stored in piles up to five feet deep without damage by pressure. Most lettuce leaves are apparently very easily damaged by pressure from fingers, but the outermost leaves are so resilient that the plants can safely be thrown some distance into collecting bins.

The introduction of a computer to control operations in the milking parlour is intended to relieve the stockman of various tasks. A project has been set up in cooperation with the National Institute for Research in Dairying, and the first step will be to calculate and feed the appropriate ration to each cow as it is automatically identified in its stall. The end of milking will be indicated for each cow and the computer will record each animal's yield. It will then calculate the feed ration for the next milking. When the project has progressed this far, other factors affecting the cow's performance, such as weight, health, and prices of feed and milk, will be included in the calculations.

NEW WORLD

Perverse Reaction to Pornography Report

by our Washington Correspondent

NOTHING hurts like the truth, the President's Commissioners on Obscenity and Pornography must have been murmuring to each other last week as they read some of the smuttier attacks on their personal motives and competence occasioned by the publication of the commission's report. From dissenting colleagues to outraged Congressmen there were few who had a kind word for the commission's two years and $2 million worth of labour. "This outrageously permissive commission shows how far this nation has travelled down the road of moral decadence," said Senator Byrd of West Virginia. "The most clearcut evidence about the slipshod, sometimes questionable and sometimes unscientific procedures of the commission has come from a witness . . . (in whose opinion) the commission's report is so grossly inadequate that one cannot help suspect that it was written with a predetermined conclusion in mind," Senator Dodd of Connecticut insinuated. Perhaps the most outspoken attack so far has been made by Mr Charles H. Keating, the only member of the commission to be appointed by President Nixon, who seems not to have participated in many of the commission's meetings. His reasons are made clear in a 150-page dissenting report, which gives an unusual amount of space to the opinions of St Paul of Tarsus but also contains remarks such as "In the case of the Commission on Obscenity and Pornography, with men such as Jack Valenti and Abe Fortas in key advisory roles in the Johnson Administration, it was more likely than not that the orientation of the commission for permissiveness would be exactly the opposite to the orientation intended by Congress, namely, for moral discipline and responsibility." It is true that with the approaching congressional elections there is little advantage for public figures in praising the commission's politically controversial findings. Nevertheless, the way in which White House spokesmen repudiated in advance the reports of both the pornography commission and, to a lesser extent, of the recent Scranton commission on campus unrest, is a disturbing token of the Administration's respect for the rationale of disinterested inquiry on which such commissions are predicated.

What did the commission say that has so shocked respectable citizens? It called for a repeal of laws banning the sale of pornography to consenting adults, on the one hand, and tighter regulations against sale of sexual materials to young persons on the other. The principal reasons for the former recommendation were, first, that "empirical research designed to clarify the question has found no evidence to date that exposure to explicit sexual materials plays a significant part in the causation of delinquent or criminal behaviour among youth or adults". Second, that the commission believes it is "exceedingly unwise for government to attempt to legislate individual moral values and standards" and that there is no warrant for continued government interference with the full freedom of adults to "read, obtain or view whatever material they wish". Third, the commission found no consensus among the population at large that explicit sexual materials (the commission's sanitized word for "pornography") should be banned and, moreover, a sizable fraction of the population—87 per cent of adult men and 70 per cent of adult women—have been exposed at some time in their lives to such material, in most cases of their own accord.

These opinions are backed by a formidable quantity of empirical research which, when it is finally printed and given to the world, will occupy ten volumes of data. The bulk of the research consists of 39 studies ordered by the commission into themes ranging from "reactions to viewing films or erotically realistic heterosexual behaviour" to "the sociological and psychological attitudes, experiences and behaviour of the consumer population of the San Francisco marketplace for erotic literature and films".

The commission in its investigations has uncovered much curious information and has come out of its underworld burrowings with no lack of wisdom to offer—"There are no great fortunes to be made in stag film production" is one of the products of this experience. But the hard core of the commission's probings is the research projects designed by its effects panel under Dr W. Cody Wilson. From early on in its work the panel addressed itself to studying three specific problems, the relationship between pornography and crime, the comparative experiences with pornography of the normal population and of juvenile and adult sex offenders, and controlled experiments into the effect of pornography on sexual behaviour, attitudes and emotions.

On the first point, the connexion between pornography and sex crimes, the verdict is that analyses of crime rates in the United States "do not support the thesis of a causal connexion between the availability of erotica and sex crimes among either juveniles or adults", although because of the limitations of method the data cannot be said absolutely to disprove such a connexion. Much argument has taken place about whether the repeal of pornography laws in Denmark has been accompanied by a decrease in sex crimes; the commission's clear conclusion is that there has been a decrease, after all differences of reporting and legislation have been taken into account.

Turning to delinquency, the commission concludes first that most American youth is acquainted with erotic materials and, second, that there is no significant difference between the experiences of delinquents and non-delinquents. The experimental studies to determine the psychosexual effects of pornography were published long before the commission finalized its report (see *Nature*, **227**, 772; 1970). The main findings here are that people's established patterns of sexual

behaviour are very stable and are not altered substantially by exposure to pornographic material. "Straight" forms of pornography are more stimulating than the perverse varieties and "while males tend to judge erotic stimuli as more arousing than females (*sc.* than females do), the sexes do not differ substantially in physiological–sexual response to these stimuli"—meaning, presumably, that women and men are equally aroused by explicit sexual material but the former are less inclined to say so.

COOPERATION

Europe, DOD and the Shuttle

by our Astronomy Correspondent

In Washington as in Paris, views are crystallizing around the space tug concept as the possible European contribution to the next-but-one phase of NASA's manned spaceflight programme, the space shuttle project which NASA expects to be concentrating on once the Skylab programme is over. A European contribution of not more than $1,000 million is being talked of, which would still be enough to give Europe the ten to fifteen per cent share in the entire programme which, it is felt in Paris, would give Europe a say in the programme. About $6,000 million spread over six years is the anticipated United States expenditure if the shuttle is to be working by 1977 or 1978. This year $80 million has been requested for vehicle and engine definition and preliminary design, and $35 million for technology studies. In June, contracts were awarded to McDonnell Douglas and to North American Rockwell to produce preliminary designs for the vehicle, and to Aerojet General, Rocketdyne and Pratt and Whitney for designs of the main engines. Lockheed has a contract to study the impact of the shuttle on payload design and costs.

But an additional variable in the European negotiations revealed last week by Mr Dale D. Myers, associate administrator for manned space flight, is that the Department of Defense is also interested in taking part in the shuttle activities. A joint committee with representatives from NASA and the Air Force representing the Department of Defense has been meeting since last spring. The Air Force, of course, has always longed to consider manned space flight as a logical extension of its activities, until its hopes were finally dashed by the cancellation of the Manned Orbiting Laboratory last year. What the implications of the DOD's involvement are for European participation is not yet known. Would European payloads be allowed to sit in the cargo bay of the shuttle next to military equipment, for example, and would the DOD expect to have the use of the space tug? It is understood, however, that the Department of State does not see any problem in the DOD involvement in the shuttle, although the question was not mentioned during last month's talks with representatives of the European Space Conference. It seems to be generally assumed that the DOD would be free to use any part of the space transportation system.

NASA is not saying how large a European contribution they would like to see, but several ways in which Europe could participate have been drawn up by the previous administrator of NASA, Dr Thomas O. Paine, and Dr H. A. Kissinger, assistant to the President for national security affairs. For example, there could be a multinational agreement to build something like the space tug, in which case the project would be managed by the European space agency which is expected to arise phoenix-like out of the ashes of ESRO and ELDO. As an alternative, European companies could work as subcontractors for the main United States contractors, but without any transfer of United States dollars across the Atlantic so that the European companies would be supported by their governments. A third possibility is direct participation by European governments through their national laboratories. Dr W. von Braun has pointed out that the cyclic temperature facility developed at the Royal Aircraft Establishment for work on Concorde could be applied to the heating problems of the shuttle, for example.

ELDO has placed two study contracts on the space tug with groups of European companies, and according to NASA a phase A study—a preliminary analysis for feasible concepts—might be started in eighteen months or so. Like the lunar module in the Apollo programme,

Priorities in Space

by our Astronomy Correspondent

With disenchantment at NASA's future programme running high, more than usual interest surrounds the next report of the Space Science Board of the National Academy of Sciences. The report, which is unlikely to be published before the beginning of December, will review relative priorities and levels of support for space science activities for the next ten years. Areas covered will include lunar and planetary science, astronomy, and the life sciences. It is believed that the report now being drafted will give first priority to the High Energy Astronomy Observatory, an unmanned satellite now being considered by NASA for the mid-seventies which would be devoted to cosmic ray, X-ray and gamma ray observations. In the planetary sciences, the report will probably recommend that preference be given to in-depth studies of the planet Jupiter rather than to the two grand tour missions due to be launched in 1977 and 1979. As well as worries about developing the technology of the grand tour spacecraft, the feeling is that only scant information will be returned from the close approaches to the outer planets. The report will probably say that if a choice has to be made it would recommend more detailed studies of a single planet, almost certainly Jupiter which is coming to be regarded in much the same way as the Moon used to be as the Rosetta Stone for the solar system. It is true that to cancel the grand tour missions would be to let a rare chance arrangement of the planets go by, but the attitude of the Space Science Board would probably be that nuclear rockets that can make the journey without gravitational boosts will be available by the time knowledge of the outer planets becomes necessary. The report, "Priorities in Space", will be based on a three week conference at Woods Hole, Massachusetts, organized by the Space Science Board and with H. Friedman in the chair.

the space tug would only be able to operate in space, and it would be a general purpose ferry able to move from orbit to orbit, transfer material from the shuttle in near Earth orbit to a geostationary orbit, and possibly be equipped to land on the Moon. NASA is, of course, hard pressed for funds, but says that the European contribution is to be considered as an addition to the NASA budget rather than a substitute for part of it, although, of course, there is nothing wrong with sharing the cost of the space effort. Others have remarked that a helping of European participation will make the programme harder for Congress to cancel, but people with longer memories will say that foreign interest did not help Skybolt.

NASA continues its efforts to sell the shuttle and space station projects to the scientists, but it is problematical whether last month's conference at NASA's Ames Research Center had the desired effect. The kindest thing that some people can find to say is that the shuttle is a solution looking for a problem. Forty-five flights each year into near Earth orbits is taken as the starting point for the calculation of the economics of the programme, and on this basis the shuttle is expected to break even six or seven years after coming into service. Each shuttle will be used a hundred times. But it seems that this rate of almost one flight each week can only be justified if there is going to be a space station in the 1980s that will need regular servicing. NASA is at present working on the design of a twelve-man space station that would cost $6,000–$7,000 million for an operating life of ten years. Many people remain unconvinced that the scientific payoff from manned space stations and shuttles would be worth the effort, however, and in any case the cost of launching satellites is frequently not the chief expense.

ENERGY

Science and Power help Each Other

by our Washington Correspondent

THE Office of Science and Technology has cast itself as peacemaker and problem solver between the electric power companies and the environmentalists. This week Dr Edward David, the newly appointed President's science adviser and director of the Office of Science and Technology, released the report of a study group that aims to balance the conflicting needs of building more power plants and protecting the environment. The report's chief recommendations are that proposed sites for power plants should be announced by the utility companies at least five years in advance so as to allow public debate and approval by the relevant agencies. The pace of research in the electric power industry should be stepped up considerably in the fields of treatment of material and heat wastes, underground transmission and new forms of generation.

In his first press conference since succeeding Dr Lee Dubridge, Dr David chose to use the report as a platform for extolling the practical benefits of scientific research. "After two decades of technological advances in defence and space—many of which have not affected the everyday life of the general public directly—we are now calling upon scientists and engineers to improve the electric power system that serves our daily needs. . . . It is not too much to hope that the ingenuity and scholarship that goes with a fine research and development programme can in the future remove these issues from the need for public debate." Dr David added that "scientists all over the country have made clear their desire to work on these problems".

The President's science adviser could not have chosen a more topical issue with which to dramatize the contribution science can make to soothing the nation's domestic ills. It only took an unusually hot day last month to cause power reductions or "brown-outs" across much of the east coast. In the electric power interconnexion serving Pennsylvania, New Jersey and Maryland, seven generating units were out of action before the heat wave started and another three gave out in the course of the day, resulting in a 30 per cent reduction of the system's full operating capacity. Although unreliable equipment and shortage of suitable fuels are the chief bottlenecks in power supply at present, a shortage of generating capacity is looming large for the future. Demand for electric power is expected to triple or quadruple over the next twenty years, but environmentalists' protests are growing in measure.

In view of this impending crisis the OST study group finds it anomalous that the electric power industry collected operating revenues of $16,500 million in 1968 but invested only 0·23 per cent of this revenue in research and development. The OST report recommends a vigorous programme to iron out some of the snags in present methods of power generation and to develop new methods. A minimum of $250 million should be spent over the next seven years or so on methods of treating the various pollutants emitted by power plants, including sulphur dioxide, nitrogen oxides, tritium and other radioactive substances, and waste heat. Over the same period at least another $50 million should be devoted to research on underground transmission technology, the chief benefit of which would be to relieve the present narrow options of where to site power plants. The practicality of forced circulation or direct cooling of high power cables should be investigated along with the age old pipe dream of superconducting cable systems.

Turning to new forms of generation, the OST group would like its bets to be placed as follows. The liquid metal cooled fast breeder reactor, which received $125 million of research funds last year ($100 million of it from federal sources), should be pushed to the tune of $150 million annually over the next 15 to 20 years. It is worth investing a total sum of $500 million over 15 years on research into magnetohydrodynamics, of which the most promising application for power generation at present uses hot gas from combustion of fossil fuel. Combined gas turbine–steam turbine cycles merit a total research investment of $100 million over the next 5 to 10 years; fuel cells, because of their high efficiencies in small units, merit a similar sum over a rather longer period; and the hopes of controlled thermonuclear fusion should be given substance with expenditures rising to $200 million annually over the next 20 years. Finally, $100,000 a year should be invested in studying means of harnessing solar energy.

The OST report recommends that the National Academy of Sciences and the National Academy of Engineering should set up panels to study the long term effects of power plant emissions, both conventional and radioactive, on the atmosphere and ecosystems.

ENVIRONMENT

Oceans Off Limits to Dumpers

by our Washington Correspondent

THE United States should take the lead in prohibiting or severely restricting the use of the oceans as a dumping ground, says a report of the recently constituted Council on Environmental Quality*. The recommendation has been endorsed by President Nixon in a message to Congress in which he promises to introduce legislation implementing the council's report.

The council has found that ocean dumping does not present much of a problem at present but is likely to become rapidly more serious in the future if not checked. To the extent that this is true, there should be little opposition to the council's recommendations and much praise of its sagacity in forestalling another area of pollution. In 1968 about 48 million tons of waste was dumped at distances between 4 and 125 miles off the coasts of the United States, 80 per cent of which was dredge spoils, 10 per cent industrial wastes, 9 per cent sewage sludge and the remainder construction debris, solid waste and explosives. The council recommends that all forms of ocean dumping should be prohibited or phased out as soon as possible with the exception of certain radioactive wastes when there is no alternative form of disposal offering less harm to man or the environment. These recommendations also apply to dumping in the estuaries and Great Lakes.

Dredge spoils represent a hazard when taken from areas contaminated with the sediments of industrial wastes; about a third of the 38 million of tons of dredgings dumped off US coasts in 1968 were polluted, often with toxic heavy metals such as cadmium, chromium, lead and nickel. Industrial wastes dumped directly in the sea include acids, and the wastes from refineries, pesticide plants and paper mills. The ocean has long been used as a graveyard for obsolete munitions and, since 1963, the navy under Operation Chase has sent to the bottom nineteen liberty ships, four of them loaded with chemical warfare agents and their carriers, and the rest with explosives. Detonation of the explosives, the report says, introduces trace amounts of lead, nickel and bronze into the water.

Little radioactive material is now dumped at sea because in 1960 the Atomic Energy Commission placed a moratorium on new licences for this kind of disposal, and since 1962 the AEC's major contractors have not made use of ocean dumping.

Excluding dredge spoils and explosives, the council reckons that about 2 million tons of wastes were dumped each year in the early 1950s, increasing to 6 million tons at the beginning of the 1960s and 10 million in 1968.

The council's report recommends that having put its own house in order, the United States should take the initiative towards achieving international co-operation on ocean dumping. The government should develop proposals to this end for presentation before the United Nations Conference on the Human Environment to be held in Stockholm in 1972.

Until such time as all dumping is phased out, people who wish to discard their trash in the ocean should be required to seek a permit from the Administrator of the Environmental Protection Agency (EPA), the report says. The agency, along with the National Oceanic and Atmospheric Administration (NOAA), came into existence early this month. The administrator has not yet been appointed, but one among the several names that have been mooted is that of Mr Russell Train, the chairman of the Council on Environmental Quality. His appointment to the post would neatly resolve—or irreversibly confuse—the possible overlap in the roles of the council and the agency. The reorganization plan establishing the EPA says that the duties to be transferred to it include "so much of the functions of the Council on Environmental Quality . . . as pertains to ecological systems". In the act establishing the council these functions are defined as "to conduct investigations, studies, surveys, research and analyses relating to ecological systems and environmental quality".

DEMOGRAPHY

1984 the Era of Young Marrieds

by our Washington Correspondent

AT least one of the world's population bombs has been deftly defused and rendered innocuous. In a speech given in New York last week, Dr George H. Brown, director of the Bureau of the Census, gave his own estimates of the state of the nation 15 years ahead. Choosing George Orwell's "1984" as a point of departure—a date Orwell is said to have appointed by no more serious a method than permuting the last two digits of the year in which he was writing—Dr Brown sketched out an apocalypse strangely similar to the present. The basis of this prediction is the prospect of a stable population in the light of the bureau's downward revision of its estimates of population growth.

Until last year, the bureau was predicting an increase of from 80 to 160 million people by the year 2000. But in the face of fertility rates that have steadily dipped from 3·35 children per woman in the 1950s to 2·45 in the late 1960s, the bureau is now only betting on an increase of 35 to 45 million people over the present level of 204 million by 1984, Dr Brown said. "However, fertility rates could well drop below current levels in view of the current concern with the effect of population growth on the environment, and possible changes in the laws on abortion." Population growth rate will inevitably rise for the next decade because the proportion of women in childbearing ages will increase. "On the basis of present information, however, the population growth rate could well return to its present levels in the eighties or, perhaps, slip below it."

The age structure of the population predicted for 1984 differs from that of the present since a third of the expected increase will occur in the 25 to 34 year age group. There will be virtually no change in the number of people between 45 and 64. "The most significant fact about the expected change in age composition is the very sharp increase in the number of persons in their 20s and early 30s. The meaning is clear: the next 15 years is the era of the young married."

Such an age structure could mean a shortage of experienced older men for positions of leadership in government, industrial management and politics. There could be pressure on some older men to postpone retirement.

NEWS AND VIEWS

Another One for the Book

PUNTERS betting on the molecular biology handicap, where scientific reputations are at stake, have taken a trouncing in the past few months. First the central dogma, or, to be more precise, the popular misconception of the central dogma, was shown to be an oversimplification. Now another firm favourite has been shaken. On page 227 of this issue of *Nature*, Chamberlin and his colleagues report, against all the betting, that when the bacteriophage T7 infects *E. coli*, the phage genome specifies a complete RNA polymerase molecule, rather than a sigma factor with the capacity to subvert the pre-existing RNA polymerase of the bacterium to the transcription of the phage genome.

In *E. coli*, RNA polymerase comprises the so-called core enzyme, which catalyses the formation of phosphodiester bonds between successive nucleotides of an RNA molecule, and a sigma factor, which programmes the core enzyme to transcribe only certain genes. The sigma factor transiently associates with the core and the complex is able to recognize the initiation sequences of certain genes. Once the initiation of transcription has been achieved, the sigma factor dissociates and is free to programme another core molecule, while the core, once it has completed the round of transcription, is free to associate with a different sigma factor. This mechanism seems to be an economical way of providing RNA polymerase with specificity, and, assuming a battery of different sigma factors and a set of core molecules, it is easy enough to devise schemes to account for the regulation of gene expression.

As soon as the first sigma factor of *E. coli* had been discovered, there was speculation that bacteriophages might bring about the transcription of the phage genome, at the expense of the transcription of the bacterial genome, by specifying one or more species of sigma factors which are able to initiate the transcription of phage DNA but not bacterial DNA. This scheme has two prerequisites: first the phage sigma factor must be able to displace host sigma factors and, second, the phage gene which specifies the first species of phage sigma factor must itself be recognized by the core enzyme complexed with a bacterial sigma factor.

Chiefly as a result of the work of Travers and his collaborators and Bautz and his colleagues, we know that the transcription of phage T4 genomes in *E. coli* follows this pattern. One of the first products of transcription and translation of the phage genome is a phage sigma factor which then allows the transcription of other phage genes. Furthermore, in the later stages of the infection, a second phage protein, which may well be another sigma factor, is made and this permits the expression of the late genes of the phage. With the precedent of T4 in mind it was not surprising that Summers and Siegel (*Nature*, **223**, 1111; 1969) assumed they had discovered yet another sigma factor when they found that the protein specified by gene 1 of phage T7 is made early in infection and seems to be required for the transcription of the T7 genome. What made this interpretation particularly seducing was the finding that *in vitro* the gene 1 protein transcribed the DNA of phage T7 to a much greater extent in the presence of *E. coli* RNA polymerase than in its absence.

But there were two flies in this balm: Summers and Siegel found that, *in vitro* at least, the product of gene 1 of T7 phage was unable to displace host sigma factor from core, and, more importantly, T7 infections were found to be insensitive to rifamycin, a drug which inhibits *E. coli* RNA polymerase. At that time the first of these findings seemed unimportant because, although the putative T7 sigma factor failed to displace host sigma factor, the product of gene 1 seemed to bind to core enzyme of *E. coli*. The second observation raised a more awkward question: how do T7 infections proceed normally in the presence of rifamycin if the core enzyme of *E. coli*, which is sensitive to this drug, is involved in the transcription of the phage genome? Summers glossed over this objection by arguing that because T7 messenger RNAs are unusually stable, and assuming that the whole of the T7 genome is transcribed very soon after infection, the presence of rifamycin rapidly becomes immaterial.

Clearly Chamberlin, with perspicacity, was unconvinced, believing that the failure of rifamycin to block T7 infections was highly significant. He and his colleagues isolated the product of gene 1 of T7 and found that it was a complete RNA polymerase capable of transcribing the T7 genome, and physically and biochemically quite distinct from the host enzyme. Furthermore, the T7 enzyme is resistant to rifamycin. With hindsight it is easy to see why Summers and Siegel, along with most people including some of the mandarins, were led astray, especially at a time when sigma factors were being invoked to explain every and any example of controlled gene expression. It was their misfortune to be dealing with a protein which has one particularly unusual property. T7 RNA polymerase loses its activity in dilute solutions unless it is stabilized by some other protein. This stabilization, as Chamberlin *et al.* have shown, is not specific; bovine serum albumin, for example, does the job perfectly well, and Summers and Siegel's experiments prove that *E. coli* RNA polymerase is also effective. When they found that the product of gene 1 of T7 transcribes T7 DNA *in vitro* in the presence but not in the absence of *E. coli* RNA polymerase, they were detecting this stabilization phenomenon and not, as they suggested, the association of a T7 sigma factor with the core enzyme of *E. coli*.

If the transcription of the genomes of T7 and T4 is so different, speculations about the role of sigma factors in eukaryotic cells will have to be taken with packets, not pinches, of salt.

Solutions Not Yet Polarized

THEORIES to explain polarity in bacterial operons, which is the topic of a contribution from Imamoto this week (page 232), have abounded since the phenomenon was first described in 1963. "Polarity" describes the observation that a nonsense mutation in one gene of a bacterial operon may not only inactivate the protein which that gene specifies, but may also reduce the amounts synthesized of the (normal) proteins coded by the subsequent genes in the operon. There is a gradient of polarity along the gene because the magnitude of the polar effect depends on the position of the mutation: the greater its distance from the end of the gene, the greater the reduction in synthesis of the subsequent proteins. Because polarity is caused only by nonsense codons—the signals for termination of protein synthesis—the most obvious explanation is that the premature termination of protein synthesis in one gene can in some way affect the ability of ribosomes to translate the messenger RNA corresponding to subsequent genes. "In some way" has led to complicated theories to explain how ribosomes translate polycistronic messengers, and although there is not yet any complete explanation, many polar effects can be explained at the level of translation.

But a bizarre effect which is more difficult to explain is how polar mutants interfere with messenger RNA synthesis. Strongly polar mutants of the tryptophan operon of *E. coli* (which has been extensively used to study polarity because of the development of a hybridization assay to measure its mRNA) contain *trp* messengers which are shorter than usual; these seem to contain only the RNA sequences corresponding to the region of the operon before the mutant site.

This is difficult to explain, because it implies that nonsense codons can affect transcription as well as translation. But two types of theory have been proposed to account for this. Morse and Yanofsky (*Nature*, **224**, 329; 1969) have suggested that the RNA corresponding to the more distant regions of the operon is made, but is not usually detected because it is very unstable. They supported this contention by demonstrating that very short-lived *trp* mRNAs could be detected by hybridization only by using very short pulse doses of radioactivity. They suggested that its rapid degradation might be caused by the dissociation of ribosomes from the messenger at the nonsense mutation, which would leave the far regions of the messenger unprotected against nucleases. The gradient of polarity could be accounted for if ribosomes were able to reattach at the next cistron after the mutation; the probability of degradation would then depend on the distance unprotected between mutation and the end of the cistron.

An alternative idea is that transcription as well as translation come to an untimely end at the nonsense codon, and Imamoto presents evidence to support this concept (page 232). He too observes that polar mutants contain rapidly degraded *trp* mRNA, but differs from Morse and Yanofsky in finding that it represents the early part of the operon before the mutant site; mRNA for the genes beyond the mutation does not seem to be synthesized at all.

If transcription does stop at or near the nonsense mutation, the RNA synthesized so far could be released from the DNA prematurely, and might therefore become available to nucleolytic attack. But why should transcription stop at a nonsense codon? Imamoto suggests that RNA polymerase continues past the mutant site, but because the RNA which it synthesizes is not translated, enzyme and product may become entangled, jamming the polymerase in position on the DNA. This would prevent passage of any other polymerase molecules, and stop transcription. The probability of this interaction taking place would depend on the length of messenger left before the next cistron where it could be reloaded with ribosomes; this accounts for the gradient of polarity.

There is no obvious way to reconcile the different results obtained by Morse and Yanofsky and by Imamoto—they have, after all, been working with the same system. One possible way out is that they use different methods to de-repress the tryptophan operon; another is that there are slight differences in their hybridization assays and the ways in which the results are worked out. But for the while, at any rate, you reads your paper and you picks your theory.

ENZYMES

Dehydrogenases Disclosed

from our Molecular Biology Correspondent

THE dehydrogenases are a ubiquitous family of enzymes which have in common their association with NAD or NADP as co-factors, and have provided a secure livelihood for countless biochemists over the years. More recently, as a consequence of some spectacular progress in their enzymology, sequences and crystallographic structure, they have formed a major growth point. In structural terms most is now known about glyceraldehyde 3-phosphate dehydrogenase (GAPDH) and lactate dehydrogenase (LDH). Harris and his colleagues have determined the sequences of GAPDH from pig and from lobster muscle—no small task, for they contain 332 and 333 residues per chain, there being four identical chains in each native enzyme.

Now Jörnvall (*Europ. J. Biochem.*, **16**, 25; 1970) reports the sequence of the even longer chain of a horse liver alcohol dehydrogenase (LADH), which has 374 residues. The result establishes that the enzyme, which is a dimer, has identical subunits. There is perceptible homology with the GAPDH sequence only towards the N-terminal end of the chain. The essential, highly reactive, cysteine is residue 46, whereas in GAPDH it is at 149 (where indeed it also is in LDH). Positions 149 in LDH and 46 in GAPDH are both occupied by tyrosines, and it is an interesting speculation, if per-

haps a long one, that these residues are interchangeably juxtaposed at the active site. The histidines are mostly in the N-terminal region, and Jörnvall suggests that it may in fact house most of the enzymatically important elements. Some support for this notion comes from his second paper (*ibid.*, 41): LADH is present in the liver as a set of three isozymes, made up from two types of subunit, E and S. The sequenced species is EE. Examination of tryptic fingerprints of the SS form reveals only six differences, five of which occur in the N-terminal half of the sequence. The isozymes show differences in specificity, and the results suggest, if they do not prove, that some at least of these residues participate in the catalytic function. The suggestion of active site residues predominantly in the N-terminal portion is not at all inconsistent with the situation in LDH, as revealed by the X-ray work of Rossmann's group. The crystallography of LADH is progressing in Sweden, and a comparison with LDH should be highly instructive.

The reactive thiol group is evidently not a universal feature of the dehydrogenases. Malate dehydrogenase, for example, is not inactivated by thiol reagents until nearly all the many cysteines have reacted. Anderton (*ibid.*, 562) has shown that reaction with iodoacetamide at a level of two moles per mole of dimeric enzyme does cause inactivation, but its site of action is a histidine. Anderton and Rabin (*ibid.*, 568) find, further, that the reaction is strongly inhibited by NADH, less so by NAD, and strongly by NAD and the inhibitor, oxaloacetate, together. This indicates the formation of an abortive ternary complex, a phenomenon also observed in other dehydrogenases.

Cooperative ligand binding by dehydrogenases is a far from neglected topic. Some of the enzymes show marked cooperativity, others do not, and yeast GAPDH is interesting in that it can behave in both ways, according to the temperature. Its NAD-binding profiles, and the kinetics of the binding process could, it was concluded, be described in terms of a two-state, all-or-none binding scheme, and not by a sequential model. Last words, however, are rarely uttered in this area; for there is, it sometimes seems, a terrible purgatory for the protagonists, who are forced to wander for all eternity through the labyrinths of positive and negative cooperativity. Cook and Koshland (*Biochemistry*, **9**, 3337; 1970), using four parameters to fit the saturation curves, assert that the best fit is to be found in a mixture of positive and negative cooperativity, that is to say, the binding at one site may promote or hinder that at another. The first binding constant is small, the second larger, the third larger yet, but the fourth is small. They base the necessity for such a scheme principally on a break in the Hill plot—though the negative interaction is not clearly reflected in the magnitude of the slope after the break. Readers must judge for themselves whether the better fit to the observed points is worth the price of two extra parameters.

CELL COMPONENTS

Sequences and Particles

from our Nucleic Acids Correspondent

THE suggestion that uncharged tRNAs have tertiary structures different from those of tRNAs charged with amino-acids has been pursued by Danchin and Grunberg-Manago (*FEBS Letters*, **9**, 327; 1970) working on oligo-C binding by tRNA. Oligonucleotides are known to bind complementary sequences not already involved in base pairing, and Danchin and Grunberg-Manago have examined whether there are differences in the availability of such sequences (in this case, runs of G) between charged and uncharged tRNAs, by comparing their binding constants with oligo-C. These were determined rapidly because labelled oligomers bound to the tRNA (at physiological *p*H) can then be co-precipitated with the tRNA and retained on Millipore filters, while unbound material is washed through. The validity of the method was checked by equilibrium dialysis. In the cases of mixed *E. coli* tRNA, pure *E. coli* $tRNA^{val}$ and pure yeast $tRNA^{phe}$, the binding constant of the charged tRNA for $(Cp)_4$ was five to ten times greater than that of the uncharged tRNA. The magnitude of the binding constant was similar to that calculated by other workers for two adjacent GC pairs. They therefore suggest that a sequence of two G residues is exposed when the tRNAs are charged. This sequence is normally unavailable when the tRNAs are uncharged. Because the mixed tRNA behaved in the same way as the purified species, the sequence involved must be common to most tRNAs, and Danchin and Grunberg-Manago speculate that the two G residues in the dihydroU loop are responsible.

In the past few years, several models of ribosomal subunit structure have been proposed, in most cases suggesting that much of the ribosomal RNA is on the surface of the sub-particles. These are now increasingly disbelieved, and a further jolt to the wire and golf-balls has been administered by Serdyuk, Smirnov, Ptitsyn and Federov (*FEBS Letters*, **9**, 324; 1970), who have studied the internal density distribution of 50S ribosomal sub-particles from *E. coli*. They estimated the radius of gyration of the particle by means of small angle X-ray scattering, and also measured its diffusion coefficient. For spherical particles of uniform density, there is a simple relation between the radius of gyration and the diffusion coefficient. But the diffusion coefficient measured in this case leads to a value for the radius of gyration 20 per cent higher than that observed. Serdyuk *et al.* exclude the possibility that this arises from imperfections in the sphere, such as hollows on the surface, after work with ebonite models. The particles must therefore have a non-uniform density, with a core denser than the peripheral areas. They suggest that this could arise if the RNA component was, on average, nearer the centre of the particle than the protein.

Further information about the fine structure of the ribosome will certainly be obtained with the electrophoretic techniques being used to fractionate ribosomal proteins by Kaltschmidt and Wittmann (*Anal. Biochem.*, **36**, 401; 1970). They have described their method of two dimensional electrophoresis through polyacrylamide gel, which permits the fractionation of as many as fifty ribosomal proteins. The electrophoresis is carried out first in a tube of gel (8 per cent, *p*H 9·6) and then in a slab (18 per cent, *p*H 4·6). The method can be applied to the proteins of the 70S ribosome of *E. coli*, and also to the 30S and 50S subunit proteins. If the fingerprints of the subunit proteins are superimposed, a picture identical to the 70S protein fingerprint is happily obtained. The versatility of the method is also demonstrated by fingerprinting ribosomal

proteins from the strains B and K12 of *E. coli*. In confirmation of previous results, no differences are detected between the proteins from the 50S subunits, but two changes are evident between the 30S subunit proteins.

LACTOSE OPERON

Release of Repression

from a Correspondent

PEOPLE who thought that they knew everything about the lactose operon of *E. coli* must stand confounded by reports that its transcription is controlled in two ways. According to traditional wisdom, a repressor protein binds to the operator, preventing RNA polymerase (which binds at the preceding promotor site) from proceeding into the operon to synthesize messenger RNA. The operon is switched on when this repressor is released from the DNA by β-galactoside inducer (the substrate for the enzymes coded by the operon).

But releasing the repression, although necessary, is not sufficient for full expression of the operon. This requires another control system, which was discovered by studying the effect of glucose in depressing the synthesis of many inducible enzymes in bacteria. Glucose has this effect because it reduces the amount of cyclic AMP in the cell. Reasoning that this nucleotide is unlikely to interact directly with the components of the operon, Zubay, Schwartz and Beckwith sought a protein factor which might mediate its effect.

They report (*Proc. US Nat. Acad. Sci.*, **66**, 104; 1970) the isolation of a mutant unable to grow on lactose or arabinose—a characteristic of a mutant lacking the protein factor, because both the lactose and arabinose operons are susceptible to the glucose effect. Using a DNA-dependent β-galactosidase synthesizing system, they could not synthesize this product of the lactose operon *in vitro* when the supernatant components were derived from the mutants, but they could do so with the corresponding extracts from wild type cells. They have purified an activity that seems to reside in a protein of molecular weight 45,000.

Starting from a biochemical instead of a genetic point of view, Pastan and his colleagues sought a protein that could bind cyclic AMP. They, too, found a protein of molecular weight about 40,000 (*Proc. US Nat. Acad. Sci.*, **66**, 480; 1970). Mutants unable to respond to cyclic AMP had a protein with an altered affinity for the nucleotide. The only significant difference between the two groups apart from the name ascribed to the protein (CAP to Zubay *et al.*, CR to Pastan *et al.*) is a two order magnitude difference in the binding constant for cyclic AMP. Although cyclic GMP competes with cyclic AMP for the protein, no other nucleotide binds.

The cyclic AMP binding protein probably acts at the promotor, for mutations at this site affect the response of the lactose to cyclic AMP (*Proc. US Nat. Acad. Sci.*, **66**, 773; 1970), and this genetic analysis is nicely complemented by the finding that the amount of messenger RNA synthesized by the lactose operon correlates with the level of β-galactosidase produced in response to cyclic AMP (*J. Biol. Chem.*, **245**, 2259; 1970). This implies that, as a result of its interaction with cyclic AMP, the binding protein helps the initiation of transcription at the promotor of the lactose and other operons.

Surprises are also in store so far as the interaction of the repressor and operator itself is concerned. Riggs *et al.* (*J. Mol. Biol.*, **48**, 67; and **51**, 303; 1970) have shown that nitrocellulose in the form of membrane filters may be as powerful a tool as nitrocellulose in the form of centrifuge tubes. They have taken advantage of the way in which repressor protein sticks to these filters but double stranded DNA does not. This means that only the DNA that interacts with the protein is trapped on the filter.

DNA trapped on the filter can be released by addition of IPTG (an inducer of the lactose operon). The rate of dissociation of the complex can be measured by following the disappearance of radioactive DNA counts from the filter when unlabelled DNA is added after a radioactive complex has been formed. An unexpected result was obtained by changing the concentration of IPTG; the inducer increased greatly the rate of dissociation of the complex. Another small molecule, nitrophenyl-fucoside, which opposes the effect of IPTG *in vivo*, decreased the rate of dissociation of the complex.

One of the popular models for the action of the repressor is ruled out by the finding that these small molecules directly affect the release of repressor from the operator. This is the conventional allosteric model which suggests that there is a rapid equilibrium between free and bound repressor, and inducers (or anti-inducers) bind only to the free repressor, thus blocking its DNA binding site. The scheme would predict that the rate of dissociation of repressor from DNA would not be affected by inducer concentration. But the inducer seems to pry the repressor off the DNA, probably by binding to an independent site on the repressor. Another surprise revealed by this technique is that glucose, hitherto thought to exert its effect on repression only by altering the amount of cyclic AMP, seems to interact directly with the repressor as an anti-inducer. But the significance of this effect *in vivo* may be limited, for it takes place *in vitro* only at unphysiologically high levels of glucose.

TRANSCRIPTION

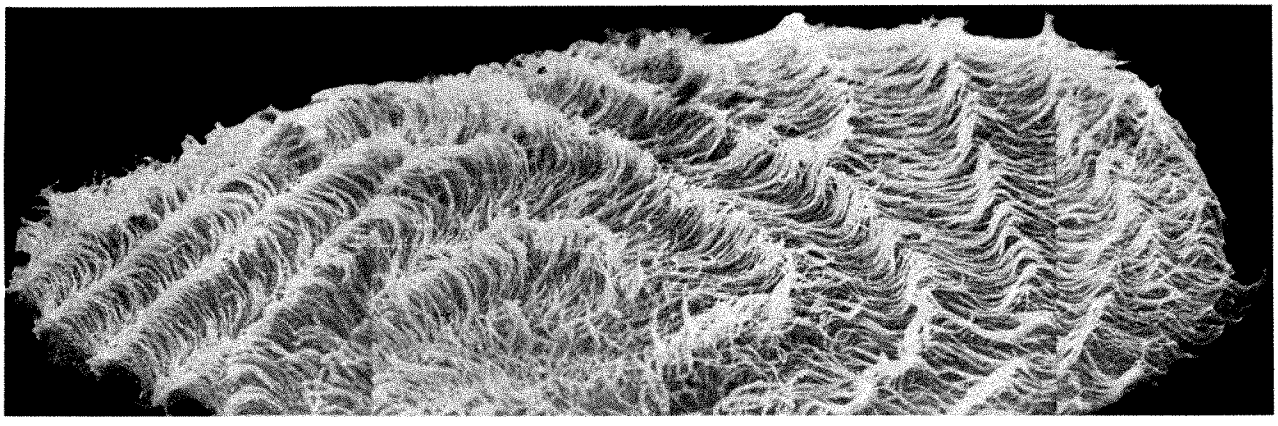
Approaching the *in Vivo* System

from our Nucleic Acids Correspondent

RECENTLY, molecular biologists have come to realize that the instant transcription or replication of DNA offered by the use of purified enzymes *in vitro* may differ significantly from the way in which these processes take place within the cell. The present fashion is to regard these activities as catalysed by cell organelles rather than individual enzymes, and accordingly, two articles in the current issue of the *Journal of Molecular Biology* report the isolation of structural complexes from the cell which contain all the components necessary for transcription or replication.

Pettijohn *et al.* (*J. Mol. Biol.*, **52**, 281; 1970) have established an experimental system for studying the transcription of ribosomal RNA cistrons *in vitro* from *E. coli* or *Bacillus megaterium*, which must at least approximate to the real situation. *In vivo*, the rate of transcription of the ribosomal RNA cistrons is as much as 100 times greater than mRNA copying in bacteria. Pettijohn *et al.* have been able to purify a DNA-protein

complex *in vitro*, which contains RNA polymerase as the principal protein attached to the DNA. When radioactive nucleoside triphosphates were added to the complex, synthesis of RNA was observed. This radioactive RNA had the high G : U ratio characteristic of ribosomal RNA, and hybridized efficiently to bulk DNA when the input level of RNA was low. Unlabelled 16S and 23S rRNAs competed efficiently with the synthesized material in hybridization. The unsurprising conclusion was that this DNA-protein complex was engaged chiefly in rRNA synthesis. Pettijohn *et al.* also referred to unpublished results showing that the RNAs released in the course of the synthesis had sedimentation coefficients of 23S and 17S. From the amount of rRNA synthesized in the time the reaction continued, they calculate that as many as 100 RNA polymerase molecules are attached to each 23S RNA cistron. This is close to the packing limit. Although these findings explain the very high rate of rRNA synthesis, the central problem is still the cause of the high rate of initiation of transcription of tRNA cistrons, by comparison with mRNAs such as the tryptophan operon.



Fuchs and Hanawalt (*J. Mol. Biol.*, **52**, 301; 1970) have described the isolation of a DNA-protein complex from *E. coli*. They believe that this is the growing point, or fork, which arises in the semi-conservative replication of DNA, where the two strands of the chromosomal DNA are parted, enabling the complementary strand to be synthesized on each of the original strands. Their secret lay in lysing the bacterial cells with a non-ionic detergent which did not dissociate the DNA-protein complex. The newly synthesized DNA in the neighbourhood of the growing points was specifically labelled with brief (10–30 s) pulses of radioactive thymine or thymidine immediately before lysis. The lysates were sonicated, and the labelled DNA-protein complex could be purified from the bulk DNA about 100-fold by successive sucrose gradient centrifugation.

They investigated the complex by treating it with various enzymes, among other things. Both micrococcal nuclease and pronase caused rapid dissolution of the complex, as expected. Phospholipase, however, had no effect on stability. This is interesting, for it is commonly thought that the growing point is attached to the membrane of the bacterial cell. Nevertheless, it is possible that the growing point regions isolated by Fuchs and Hanawalt were detached from the membranes during lysis, while still retaining some structural integrity.

Perhaps their most significant finding was the negative result that there is virtually no DNA polymerase activity in the complex proteins, as judged by a standard assay for this enzyme. Furthermore, a mutant of *E. coli* described by De Lucia and Cairns which lacks active DNA polymerase nevertheless yields the same amount of the labelled complex as the wild type. It is difficult to avoid the conclusion already suggested by the viability of such mutants, that the DNA polymerase known and loved is not the enzyme of replication.

PROTOZOA

Waves Caught by the Camera

This is not a bath mat, but a composite electron micrograph of the protozoan *Opalina*, which has been fixed instantaneously and dried by the critical point method. The preparation of S. Tamm and G. Horridge (*Proc. Roy. Soc.*, **175**, 219; 1970) has preserved waves of movement passing through the cilia (×3,000).

FIBRES

Spinning a Yarn

from a Correspondent

DEVELOPMENTS in the fibre and textile industry seem to be coming thick and fast. New flame resistant textiles, fibres for reinforcing composites, and fibres from films were some of the topics for discussion at an international seminar, organized by the Shirley Institute in Manchester from September 29 to October 1.

Contributions concerned with new developments emphasized two approaches: the modification of existing fibres and the development of new fibres. Cotton and wool, two of the oldest fibres, can be modified to such an extent now that in some of their finished forms they must be regarded as "new" textiles. Dr H. R. Hardy (Courtaulds Ltd) described how viscose rayon, one of the oldest man-made fibres, has been developed into a range of new products. Among the most important of

these viscoses are the new "high wet modulus" fibres, which have much improved mechanical properties and dimensional stability, especially when wet.

Dr J. W. S. Hearle (University of Manchester Institute of Science and Technology) summarized the diverse views held on the structure of fibres, and Dr J. D. Owen (Shirley Institute) showed that the "handle" and "feel" of fabrics are at last beginning to be understood in terms of measurable physical properties. A good example of the application of basic research to fibre development was provided by Dr C. Mazzolini (Chatillon), describing the development and properties of a new syndiotactic PVC fibre. This fibre, in which the chlorine atoms are arranged symmetrically with respect to the polymer chain, is much more resistant to heat and dry cleaning solvents than the ordinary atactic PVC fibre, and is thus suitable for a wider range of applications.

The full scope of progress in the textile industry was demonstrated most effectively by the contributors who described new methods of producing yarns and fabrics. In the "melded" (melt-welded) technique for making fabrics, described by Mr K. West (ICI Fibres Ltd), a special sheath-core bicomponent fibre is used; the sheath has a lower melting point than the core. The fibres are formed into a web-like fabric structure, and then heated to a temperature hot enough to melt the sheath components and cause fusion at the points of contact between fibres; with cooling an excellent fibre bond is obtained. Mr. J. E. Ford (Shirley Institute) and Mr O-B. Rasmussen (Rasmussen Ingeniorfirma) discussed new methods by which polymer film can be converted into fibres. The films are first stretched to orient the molecular structure, and then subjected to lateral mechanical forces, which act on the natural tendency of oriented film to fibrillate, and thus convert the film into a fine network of fibres. Contributions on spun bonded fibres, from Dr O. L. Shealy (Du Pont), and on the Bobtex ICS spinning technology, from Dr A. J. Bobkowicz (Bobtex Corporation), completed the indication of things to come.

METALLURGY

Splat-cooling and Kindred Trades

from our Materials Science Correspondent

THE "new technique" of splat-cooling stole the limelight at the international conference on metastable metallic alloys in Brela, Yugoslavia, at the end of September. The conference, held on the initiative of the Institute of Physics of Zagreb University, and with the support of IUPAP and the European Physical Society, was devoted almost solely to the novel phases created by ultra-rapid quenching of alloys, direct from the molten state, by impact of drops against a cold metallic substrate—splat-cooling.

By means of splat-cooling a new family of metastably extended solid solutions, new phases that do not appear in the equilibrium diagram, and amorphous phases can be generated. Their interest lies not only in the regularities governing their appearance but also in their physical and mechanical properties, their applications and how they set about the approach to equilibrium when they are annealed. All these matters were discussed at Brela, and so was the complementary technique of coevaporation of metals on to a cold substrate, which is even more effective in creating metastable phases but has been less widely used.

Professor P. Duwez (California Institute of Technology), the inventor of the technique, surveyed metastable phases obtained by splat-cooling. His account of new developments included Fe–P–C ternary alloys and other transition metal–phosphorus alloys, all of which display amorphous phases. a-$Fe_{75}P_{15}C_{10}$—the prefix indicates an amorphous alloy—is a soft ferromagnet which stays amorphous up to its Curie temperature of 310° C. Duwez also demonstrated a Vegard's law for a-alloys; instead of the lattice parameter, the nearest neighbour distance deduced from diffuse X-ray patterns is plotted against solute fraction and gives a straight line.

Variants on the standard splat-cooling procedures included a description by Dr B. Leontić (Zagreb) of a method of spraying liquid alloy at synchronous speed into the gap between two rapidly rotating rollers, to make long strips of metastable alloy. Professor N. J. Grant (Massachusetts Institute of Technology) emphasized that interparticle spacing in a two-phase alloy is determined by dendrite spacing or grain size, which in turn are determined by cooling rate (so that a log–log plot of these variables is a straight line over many decades). Dendrite or grain size varies from about 1,000 μm at 10^{-3} deg C/s to about 0·01 μm at 10^{8} deg C/s. Grant has utilized this knowledge, manufacturing alloys by atomizing the melt and spraying it against a copper wheel. The resulting alloys, if concentrated enough, are supersaturated but also two-phase, and have outstanding mechanical properties. This applies both to aluminium-based alloys of various kinds and to Cu–Zr alloys which combine high conductivity with great strength. The mechanical properties of an a-alloy were surveyed by Professor R. Maddin (University of Oxford) and Dr T. Masumoto. Referring entirely to Pd-20 per cent Si alloys, they demonstrated the very large hardening, without total loss of ductility, entailed in the formation of a concentrated amorphous solid solution.

Several people pointed out the need for a metalloid or non-metallic constituent (such as Si, Ge, Te or P). Professor A. Guinier (Paris) believes that this indicates that a-alloys depend on a kind of covalent bond network, analogous to oxide glasses. This comparison was also made by Professor R. W. Cahn (University of Sussex), surveying the structural and kinetic theories concerning the formation ranges of oxide glasses, and the way these relate to a-alloys. Duwez enunciated the "confusion principle": in ternaries, amorphous alloys form more easily than in binaries, *ceteris paribus*. Expressed crudely, this is because two solutes form logjams with each other and with the solvent atoms. This kind of notion has also been successfully applied to the rationalization of vapour-deposited a-alloys (which, however, do not seem to require the presence of covalent bonds). Still on a-alloys, Guinier distinguished, more clearly than has been possible before, between truly amorphous materials, exemplified by Ni–P, and microcrystalline ones, such as Pt–C; in each case, X-ray scattering was the essential tool.

Several contributions were concerned with the breakdown of supersaturated Al–Fe alloys and the assorted property changes. Dr R. Ricci Bitti *et al.* (Paris) showed that flash-coevaporation of N–Pb films depended on the formation of alloy "molecules" in flight. Other contributors dealt with electrical properties of

splat-cooled or coevaporated films (including the contentious question of whether resistivity ratios can be used to assess reliably the extent of metastable solubility).

GAMMA RAYS

Confidence Restored

by our Astronomy Correspondent

ONE may be forgiven for thinking that gamma ray astronomy is proving the least rewarding of the new astronomies, but at last quite a solid body of evidence is building up to support the claim that an extraterrestrial source of gamma rays is being observed. The breakthrough was provided by a detector in the third Orbiting Solar Observatory, which picked up high energy gamma rays (greater than 100 MeV) coming from the galactic plane, and especially strongly from the galactic centre (Clark, Garmire and Kraushaar, *Astrophys. J. Lett.*, **153**, L203; 1968). But understandable reserve has prevented hats being thrown in the air until verification was produced, especially after balloon experiments by the Case Western Reserve–University of Melbourne group cast doubt on the reality of the OSO 3 source (Frye *et al.*, *Nature*, **223**, 1320; 1969). Confusion over the OSO 3 calibration which finally resulted in a downgrading by a factor of three in the claimed intensity has not helped to inspire confidence. A report from Fichtel's group at the Goddard Space Flight Center should set the seal on the 1968 result, however (*Astrophys. J. Lett.*, **161**, L157; 1970).

During a balloon flight of a spark chamber that was being developed for use in the Small Astronomy Satellite, Kniffen and Fichtel picked up gamma rays coming from the galactic centre at an intensity corresponding to the revised OSO 3 estimate. The indications are that the origin of the gamma rays is in high energy collisions between cosmic ray protons and protons in the interstellar gas. Neutral pions produced in the collisions decay into gamma ray photons, having a flattish spectrum at these energies, a spectrum which seems to be indicated by a comparison of the intensities measured by Kniffen and Fichtel above 50 MeV and above 100 MeV. According to theoretical calculations there should also be a small contribution from bremsstrahlung by cosmic ray electrons. But it is too early yet to rule out the alternative explanation that cosmic ray electrons produce Compton scattering of the anomalously high infrared background radiation that has been recorded—questionably—during the past few years.

It is disappointing that Kniffen and Fichtel found no sign of the point source of gamma rays in Sagittarius reported by Frye *et al.* last year, but people will not be mortified. The evidence was never as solid as for the galactic source, and in any case, now that X-ray stars have been found to come and go it is no longer bad form to get round the problem by suggesting that gamma ray sources are also variable. The non-detection of the OSO 3 galactic source by Frye *et al.* remains a problem, however.

But the greatest disappointment remains the failure to detect gamma rays from the Crab Nebula—astronomy's *Escherichia coli*—against expectations that there should be a measurable source. The flux from the galactic centre, on the other hand, has turned out to be a few times more than predicted. From a balloon experiment such as that by Fichtel's group in which a large background of atmospheric radiation has to be subtracted, next to nothing can be deciphered about the second component reported in 1968 by Clark, Garmire and Kraushaar, an isotropic flux of gamma rays which seems to be present in the OSO 3 data. More satellite experiments will have to be carried out before the nature and indeed the existence of the isotropic background can be made more definite. With gamma ray astronomy now in the post-natal state, what are needed are detectors with large surface areas to be exposed for long times. This is a goal for the large lifting capability now available to the Americans.

EARTH'S MANTLE

Gravity and Global Tectonics

from our Geomagnetism Correspondent

MANY people have remarked on the correlations between certain anomalies in the geoid and surface features of the Earth—large negative anomalies, for example, seem to be associated with the deeper parts of the ocean, especially the ocean margin trenches. The problem with this type of generalization is that the low order harmonics of the geoid, which are the strongest, are much more likely to be associated with features in the lower mantle than tectonic features close to the Earth's surface. Thus unless very high harmonics are included in the geoid determination, the significance of the correlations is bound to remain in dispute.

But recently, Gaposhkin and Lambeck have made an improved determination of the Earth's gravity field (so far unpublished) from satellite data and terrestrial gravimetry, which contains spherical harmonic components of the potential complete to degree 16, and which thus gives a resolution of about 11° or 1,200 km. This has enabled Kaula (*Science*, **169**, 982; 1970) to show the Earth's gravity anomalies in much finer detail than before and to relate them more closely to the Earth's tectonic features and processes in the upper mantle.

The most interesting point to emerge from Kaula's analysis is that both ocean rises and island arc-trench systems are clearly associated with high positive gravity anomalies, which means that both types of region contain excess mass. Because excess mass anomalies can only be created by mass transfer, it seems natural to look for the source of the anomalies in terms of upper mantle convection processes—movement of the asthenosphere and the resulting lithospheric motion. But if, as seems to be the case, asthenospheric flow is essentially steady state and the moving material incompressible, it follows that any mass transfer cannot be a once-and-for-all phenomenon. What is required is a process which maintains a mass excess in particular regions of the overall flowing pattern.

Kaula lists five ways in which this could occur—the accumulation of material at the surface, the replacement of less dense by more dense material at an interior interface, transition to a denser phase, thermal contraction and petrological fractionation by which a less dense component is separated from the material before it enters the relevant region. As Kaula points out, however, the precise relationship between gravity anomalies and the flow system depends critically on the boundary conditions. If the upper boundary is fixed, an upwelling current such as that at a mid-oceanic ridge will produce a negative gravity anomaly because

of its lower density. Because the anomalies over ridges are positive, the boundary there must be free so that the effect of the mass pushed up at the surface outweighs the effect of reduced density. In an arc-trench system, on the other hand, the situation is reversed. The material approaches a fixed boundary so that the density increase has greater effect than the removal of mass from the surface.

In contrast with the rise and arc-trench systems, the gravity anomalies over the ocean basins are negative, especially close to the rise flanks. The immediate cause of this phenomenon must be that the crust carried along by the sea floor spreading is thicker than would be expected, on isostatic grounds, from the depths of the basins. But why should this be so? And why should there be a drop of several kilometres between a rise and a basin? Kaula offers alternative suggestions—either there is insufficient asthenospheric material from the rise to match the rate of spread of the lithosphere or there is a settling out of a denser component—but he does not commit himself to either.

Finally, there is a large negative anomaly over Antarctica which is more than three times too large to be attributable to glaciation, and a positive anomaly over Hawaii which is far from any oceanic rise. Although Antarctica is more than 80 per cent surrounded by oceanic rises, it is not associated with the seismicity to be expected from descending lithosphere. The rises must therefore be moving away from the continent. The negative anomaly here could also be explained by insufficient asthenospheric material. Hawaii, on the other hand, is unique in being the only land region in the world more than 5,000 kilometres from an oceanic rise. Kaula suggests that the positive anomaly there may be due to partial upwelling not directly related to the world wide ridge system.

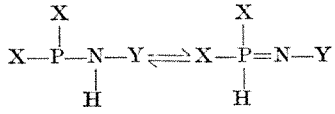
In general, however, the newly determined gravity field is compatible with the new global tectonics and allows much more sensitive correlations with surface and near-surface features.

INORGANIC COMPOUNDS

Phosphorus Looks Ahead

from a Correspondent

THERE seems to be a bright future for phosphorus–nitrogen compounds, according to trends discussed in Prague recently. These substances drew the most attention at a symposium on inorganic phosphorus compounds held in the Czech capital between September 14 and 17.

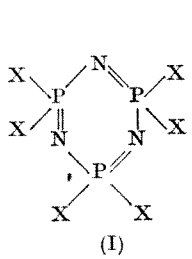


Dealing with the cyclophosphazenes, Professor R. A. Shaw (Birkbeck College, London) drew attention to the fairly wide occurrence of long range virtual coupling in the proton nuclear magnetic resonance spectra of these compounds. Recent work on their basicity has made it possible to use pK'_a measurements in structure determination, and evaluation of substituent constants has facilitated the prediction of the basicities of many compounds based on the cyclotriphosphazatriene skeleton. Novel ring opening and closing reactions of $N_3P_3Cl_6$ and $N_4P_4Cl_8$ with organometallic reagents were reported.

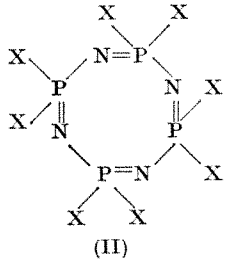
Dr H. W. Roesky and co-workers (University of Göttingen) reported some novel developments in the controlled stepwise synthesis of acyclic phosphazene units, for example,

$$R{-}NH_2 \xrightarrow{PCl_5} R{-}N{=}PCl_3 \xrightarrow{(Me_3Si)_2NH} R{-}N{=}PCl_2{-}NHSiMe_3$$
$$\xrightarrow{PCl_5} R{-}N{=}PCl_2{-}N{=}PCl_3, \text{ and so on.}$$

R represents, for example, $N_3P_3F_5$.



Drs A. Schmidpeter and K. Schumann (University of Munich) threw light on the prototropic behaviour in aminophosphazanes–iminophosphazenes, and showed how the position of this equilibrium was dependent on the nature of the substituents, both on the phosphorus and on the nitrogen atoms.



The detailed replacement patterns of $N_3P_3Cl_6$, with nucleophilic reagents, which Shaw discussed, were supplemented by preliminary data of similar reactions with $N_3P_3F_6$ from Drs E. Niecke, H. Thamm and O. Glemser (University of Göttingen). Data obtained so far suggest that patterns similar to those of the chloride pertain also with the fluoride (although the leaving group is different), but that there are some significant differences, for example, when the nucleophile is a thiolate ion.

Drs G. Wunsch (BASF, Ludwigshafen) and J. Emsley and P. B. Udy (King's College, London) described phosphorus-31 nuclear magnetic resonance studies which throw light on the mechanism of the formation of the homologous series of chlorocyclophosphazenes $(NPCl_2)_n$ ($n=3$, 4, 5 and so on). The most recent findings suggest that in controlled conditions the formation of a given ring system, such as the trimer, $N_3P_3Cl_6$, is favoured to such an extent as to make it the sole or almost the sole product of the reaction. This would represent a significant advance in the industrial use of this type of compound, for previously mixtures of the whole homologous series were obtained.

Dr G. Wunsch and Dr W. Wanék (Pedagogical Faculty, Ústí nad Labem) forecast major industrial uses for compounds based on phosphazenes. Wanék dealt with the specific application of aminophosphazenes $[NP(NH_2)_2]_n$ ($n=3$, 4, 5 and so on) as highly concentrated fertilizers. Recent legislation in the United States and United Kingdom, and other countries, concerning the degree of flammability permitted in fibres and other materials, has stimulated research on flameproofing agents. Alkoxyphosphazenes based on structures such as I and II (X = OAlk) have recently been developed as most successful flame-retarding agents for viscous rayon.

(I)

(II)

Even quite modest extrapolations of the future use in this field suggest that large tonnages would be required. Other applications of phosphazenes as plasticizers and as additives to hydraulic fluids and lubricants were also forecast.

Science Policy and Science Policy Research

by
STUART S. BLUME
Council for Scientific Policy,
Secretariat, Department of
Education and Science

This assessment of the value of science policy research in the making of policies is based on a lecture given at a meeting of the Sociology of Science Study Group of the British Sociological Association last March. The thoughts it contains are of course those of Dr Blume himself, and not of the Department of Education and Science or the Council for Scientific Policy.

In this article I want to say something about science policy research, and its relations with the process of formulating national science policy. I shall start by giving what seems to me to be a useful definition of science policy, taken from the first Report of the Council for Scientific Policy[1].

"Science policy does not (therefore) direct the advance of scientific knowledge, though it may well be concerned to encourage or to direct the application of the results of scientific advances. The tasks of science policy are of another kind: to maintain the environment necessary for scientific discovery; to ensure the provision of a sufficient share of the total national resources; to ensure that there is balance between fields and that others are not avoidably neglected; to provide opportunities for inter-fertilization between fields, and between the scientific programmes of nations."

Conscious government involvement with the organization and finance of scientific research on a scale necessitating any talk of "a share of the total national resources" dates only from the Second World War—this is as true in the United States as in the United Kingdom. On the other hand, abstract discussion of the problems of science policy by scientists, philosophers, and philosopher-scientists is rather old (consider Francis Bacon for example), and there are many classic 19th century texts, such as Babbage's "Decline of Science in England" and James Hole's Essay on Mechanics' Institutes. Later almost all governments became increasingly preoccupied both with ensuring that indigenous science flourishes and with the demands its growth makes on the national purse. During this time it seems to me that the intellectual debate has rather lost touch with reality, and now pursues a logically independent course of its own. A famous contribution to the intellectual debate is the collection of papers on "criteria for scientific choice" published in *Minerva*[2], and which includes contributions by men of the calibre of Michael Polanyi, Stephen Toulmin and Alvin Weinberg. Harvey Brooks has succinctly put some of the questions with which the debate has dealt[3]:

"To what extent should planning be left to the internal working of the scientific system ?

"Who should be involved in the setting of scientific goals at various levels of detail?

"What are the categories of classification of scientific activities for which it is appropriate to plan?"

To be contentious, I think that this debate derives more from Babbage and Hole than from an understanding of contemporary policy making. It is not what I mean by science policy research. One day it might properly be seen as a contribution to the philosophy of science. As I understand it, science policy research has to follow a narrow middle way between this *a priori* generalism and pure data-gathering—and I shall define it in this way. Fortunately I can claim as precedent Harold Lasswell's description of the objective of policy sciences in general, in his essay on the policy orientation[4]. Perhaps because they have been less worried about inducing neuroses in the scientific system, I think that economists might have contributed more to these issues of planning. One has only to compare the *Minerva* debate with the passage quoted here[5]:

"Where social costs are high but private costs lower than private benefits, regulation is often essential (e.g., pollution); or where social benefits are high but private benefits lower than private costs, there will be a tendency to underinvestment, as in the case of fundamental research itself."

Just as there may be severe limitations on the fruitfulness of the kind of *a priori* philosophical argument I have mentioned, so there may be limits to the usefulness of the attempt which they make to define and describe science policies in terms of their objectives. I should like to suggest an alternative conceptual framework, using the two dimensions instruments and influences—although some would call this "one dimensional thought".

Constraints on Policy Making

Any truth still inherent in Polanyi's dictum that science is a self-governing system probably derives less from the unshakable commitment of the scientific community to a set of norms than from the overall inertia of the system. A better image than the city state would be the fly wheel! This inertia limits what the policy maker can do, and one can probably say that policy making can function only in practice at the margin, as economists have it. For example, suppose it were thought that the ratio of scientists to engineers in the labour force were too large. All that can be done in most countries is to make relatively more engineering places available in universities, and clearly it will be many years before the composition of the work force is affected significantly. Part of the duty of the science policy maker, whether government official or, as in the United States, member of a relevant Congressional committee, is to agree on a budget for his agency with the principal agency concerned with economic regulation—or the Appropriations committee. As in any allocation process this is largely determined by previous commitment, and debate needs must hinge on determination of the most appropriate rate of growth. Again, as in other allocation processes, much of the additional subvention is absorbed by inflation of costs in existing projects (or "sophistication"), and frequently—as a consequence—new developments suffer most. In the United Kingdom as in other countries mechanisms have been devised partially to compensate for this, but new developments are, of course, of rather special significance to science. It could be argued that their curtailment affects the health of science more than the provision of less extra places affects that of higher education, or the provision of less extra hospital beds affects that of the health service.

These two examples are intended to illustrate the point that the executive instruments available to the policy

maker are rather limited. They are also crude to the extent that he cannot be entirely sure of their effect. For example, he can make available more engineering places at universities, but cannot be sure that they will be taken up. What is more, there are instruments which are not accessible to him: the market for skills in another part of the world might have implications for the agency with which he is concerned. A more sophisticated apparatus would include a feedback loop, so that some indication of the effects of a new measure could rapidly be obtained. This is largely lacking.

The system which I have described, of small uncertain steps, can be designated, to borrow Kuhn's terminology, "normal" policy making. There are, of course, occasional periods of "crisis" when more far reaching changes are made. Such "crises" may follow severe budgetary restrictions, or a review of the institutional structure of the national scientific effort such as that carried out in Britain by the Trend Committee in 1963[6]. As with scientific crises, it is not always clear which factors have been primarily responsible for their precipitation, other than the realization that an accumulation of *ad hoc* changes to an existing institutional structure has reached a stage where more fundamental changes are needed.

Although science policy is constrained by the relatively unsophisticated executive instruments at its disposal, it is also fashioned by a creative tension between the various groups to which it is of interest. This is, of course, a characteristic of policy making in any democratic polity. I need hardly point out that much recent discussion of "science and society" has been concerned with this process, though in a fashion which has been exhortative rather than analytic or prescriptive. I shall discuss some of the factors which shape national scientific policies. It is as one of these that I suggest science policy research can fruitfully be viewed, and it is in periods of crisis that it might be most relevant.

To discuss the relative power of the various interest groups would require a sophisticated political sociology of science which we cannot at present provide. At present discussion of relative power must be very specific and left to the historian. I wish only to describe the groups involved and to say something about their relationships with those who must make decisions.

Influence of Government Advisory Boards

Most advanced countries probably now possess a formally constituted standing advisory body on science policy, composed principally of eminent scientists. In addition, in many countries the national scientific academy (for example the Royal Society, National Academy of Sciences, Swedish Academy of Sciences) has some advisory role. As far as I know only Australia has in recent years rejected the formation of the former on the grounds that the latter was totally competent. Of course the functions of both types of body vary between countries, as do their relations with the variety of organs of government which exist everywhere. Beneath the highest level policy committees is usually a hierarchy of committees with more limited and more technical mandates. Sociologists have pointed out that membership of the highest committees is frequently restricted to the most eminent among the scientific community. Although this is partly because of their proven intellectual abilities, it has been suggested that their prestige is important because it vindicates their speaking "for" their discipline or some wider "electorate" (for example ref. 7). Social and political scientists, such as Don K. Price, have also suggested that in addition to the value of the advice they offer, the advisory committee of scientists has an additional value to the policy maker; because their statements are validated by the prestige of the scientific community the weight of this prestige can be used to balance the prestige of other advisory groups, for example military and economic.

Basically, then, it is by such a system of committees that governments take the advice and opinions of the scientific community on such issues as seem to them important. Although the relationship between executive and adviser obtaining in any country at a given time must be a combination of formal and informal (or individual) factors, it is of course only the former which is subject to sociological generalization.

The Legislature

The influence of any legislative body on scientific policy must depend ultimately on three factors: the constitutional limitations on legislative control; the availability of information and qualified assistance; and the interest and concern of members. As far as the first is concerned, there is no need for detailed exposition of the difference in role between, for example, the Houses of Parliament, Congress, and the Assemblée Nationale. Clearly discussion such as would be required by any real comparison demands the talents of a specialized political scientist. It is well known that US Congressional committees (such as the Joint Committee on Atomic Energy) frequently act as "protectors" of the agency under their surveillance. In Britain it is accepted that the Select Committee of the House of Commons, though having a very different mandate, performs a most valuable service. Parliamentarians commonly receive information through three sources—library services, informal contacts and "parliamentary and scientific committees", such as that in Britain, which now exist in several countries. The importance of this information requirement has been much discussed in debates on "science and society", and emphasized more formally by the OECD/Council of Europe report on Science and Parliament[8]. Interest, of course, cannot be legislated for. Although very few parliamentarians, to my knowledge in any country, have a background in pure science, there are more (though still few) with a background in applied science. On the whole, interest is in the application of science to welfare and economic aspects of social change, rather than in pure science for its own sake. Suitable indicators of interest might be membership of Parliamentary and Scientific Committees, or questions asked in the House (which has been used by Vig[9]).

The Wider Community

I would include both the scientific community and the population at large in the wider community. Clearly both have some concern with issues of science policy, though perhaps with different emphases. For such concern to manifest itself, three things are required: the latent interest, the information and a mechanism. The provision of information is partly the obligation of the media; the popular scientific press on the one hand and the mass information media on the other. It would probably be true to say that in the United Kingdom we are fortunate in the extent to which the information media meet these obligations. The Government too can encourage proper and informed public discussion, as, for example, it has

done recently with its White Paper on Public Expenditure[10] and with its Green Paper on Government Research[11], both of which are in their different ways relevant to science policy issues.

When both interest and information are in evidence, some institutional means of crystallizing and presenting opinion is required, if influence is to result from interest. Again, journals (such as *Nature* and *Science*) and the press can do this in part, but far more influence would be likely to accrue to a formally constituted pressure group (whether specially constituted or resulting from the initiative of a pre-existing group). The scientific community is, of course, highly organized—primarily on a disciplinary basis. Such scientific societies, or institutes, by virtue of their representative character, can frequently legitimately claim access to or even representation on decision-making bodies. In order truly to serve as representatives, however, it could be argued that they would have to discuss policy issues, so that officers were partly elected according to their attitudes to such issues. Price has argued that scientific bodies are exceedingly unsophisticated politically (for example ref. 12). Other means of influence are also open to them, such as lobbying the legislature and preparing published reports—such as those produced by the chemistry and physics panels of the National Academy of Sciences[13]. The social structure of science also contains a few smaller bodies formed specifically for influencing public opinion, such as the old Federation of Atomic Scientists and the British and American Societies for Social Responsibility in Science, but because of their lack of representativeness these must carry less weight and would tend to use different means.

So far as the community at large is concerned the institutional forms are on the whole lacking. Britain, the United States and Australasia do have Associations for the Advancement of Science, but these now more rarely than formerly take issue on matters of public policy. (It is interesting, however, to note the rather sudden "repoliticization" which seems to have taken place at the recent Boston meeting of the American Association for the Advancement of Science.) There also exist quite large numbers of organizations with a limited interest, though frequently in an issue bearing in some way on science and technology policy, and formed specifically for lobbying. In this category could be included the various anti-pollution bodies, as representative of organizations which do seem to have a better understanding of the instruments at their disposal than do many bodies in this area. The overall impression, however, is that the community is far less well organized for influencing scientific policy making than it is for influencing, say, economic policy making or than it would be for influencing regional planning if the recommendations of the Skeffington Report[14] were to be implemented.

Statisticians and Science Policy Researches

The production of statistics has considerable influence on policy making even though this may not be the chief objective of those who produce them. As the political scientist Robert E. Lane has pertinently observed, facts can exert a certain tyranny upon the decision-maker by their mere existence as facts: some kinds of knowledge are inevitable "pressures for policy change"[15]. Comparative statistics, in whose production international organizations such as OECD and UNESCO specialize, have a particular power. Tables on research and development expenditure as a percentage of gross national product for various countries are treated very seriously, and such comparison can be a powerful incentive to increase effort or divert resources. For example, the French Comité Consultatif recently stated that it[16]:

> "continues to estimate that the rate (of expenditure) should pass 2·5 % of GNP in 1970, to 3·0 % in 1975 and 3·5 % in 1980—representing a growth of 0·1 % per annum in the part of the product given over to R & D. . . .
>
> . . . To attain in 1980 a level of expenditure on R & D equal to 3·5 % GNP implies, in effect, that France consecrates in 12 years a percentage of national revenue approximately equal to that hitherto spent by the US".

The consideration of the role of statistics in policy making suggests that one must differentiate in some measure between the influence of the tool (the statistics) and of the worker who wields it (whoever he may be). This is a point I shall take up later.

The framework within which I propose to discuss science policy research should now be clear. In the final section of the paper I shall suggest that science policy research is only differentiated from, as it may be, sociology, political science, operations research or economics by its potential, or real, relations with the policy making process. Thus it is not possible to consider it in substantive intellectual terms as one might consider, for example, political science. I suggested earlier that research in science policy has to be distinguished from, on the one hand, *a priori* philosophizing about the social relations of science, and on the other the collection of statistical data. It does, of course, share, with the statistical information that I have discussed, a certain potential "tyranny of knowledge", and once again it is necessary to distinguish between the power of the instrument and that of the man who wields it. Furthermore, it is necessary to point out that policy research can have a critical as well as an instrumental function. That is to say, not only can it clarify the options of the policy maker, by examining such matters as "the utilization of highly qualified manpower" or "sophistication in expenditure", but it should be able to clarify and criticize the fundamental assumptions (both explicit and implicit) on which policy making is based. I should like to suggest that this must be true of any policy research, but that in other fields of decision making this duality of purpose has at least a *de facto* recognition.

Role of Research in Policy Formulation

Ben-David[17] has suggested that to increase the relevance of fundamental research to the innovation process requires not the artificial direction of such research down obviously useful channels, but that those responsible for the management of innovation be aware of what is being done and constantly assess and reassess its relevance to their own objectives. Applied research includes all fundamental research which turns out to be useful. So it is with science policy research—policy research is what turns out, or what resonably could turn out, to be relevant.

Two famous examples of what can be called science policy research are the projects Hindsight and TRACES, carried out respectively by the RAND Corporation for the Department of Defense, and Illinois Institute of Technology for the NSF. Hindsight[18] involved twenty post-war American weapons systems (innovations), seeking to assess the importance of fundamental and applied research and development in their production. It concluded that of the relevant research and development "events" leading up to the various innovations, only 0·3 per cent were fundamental research, and 92 per cent

were development. The project only included events after 1940, and neglected all that was known before this. The conclusion drawn was that, given the Defense Department's objectives, it might not be worth supporting fundamental research. TRACES[19] was a slightly later study, commissioned by the National Science Foundation (the principal mandate of which is to support fundamental research) which used a similar methodology to look at five non-military innovations (including oral contraceptives and electron microscopes)—a major difference being that the Illinois investigators looked at relevant "events" right back to the nineteenth century. Of 341 events identified, 70 per cent were fundamental research and only 10 per cent development. Apart from the superficial contradiction, two things are noteworthy in these two studies: (i) they deal with a fundamental issue of science policy, and (ii) although rather large studies they are readily reducible to very simple conclusions. For both these reasons they are easily used, and have become a part of the folk mythology of science policy. Their easy assimilation suggests a difficulty. On most issues as central as that treated there are already firmly entrenched positions; thus the influence of a piece of research may well depend on the preconceptions and influence of those who see it, as well as on its intellectual significance. (This need not horrify—it is quite analogous to the demonstration of Barber and Merton of a resistance to discovery in the scientific community.) I shall suggest later that if those who do such research had an independent organization, an independence, if this were possible, and yet the capability to do such work, there could be interesting repercussions.

But who does do science policy research? Perhaps the most famous performers of all are the American research corporations, like RAND, the Institute for Defense Analysis and the Hudson Institute. They originated towards the end of the Second World War, concerning themselves exclusively at that time with defence policy, first of a tactical and then of a strategic kind. RAND's "biographer" has given the following reasons for their appearance[20]. First, the type of scientist needed would not be attracted into the civil service because neither salaries nor conditions were at that time attractive; second, long-range thinking is difficult to cultivate in the hectic atmosphere of a policy making agency—especially "heretical" thought; third, universities seemed inappropriate because of the difficulties at that time of establishing interdisciplinary institutes; and fourth, industry was inappropriate because of conflicts of interest. These corporations frequently work entirely for the government, on a broad range of problems, and their approach includes (in Smith's words) "the broader systems approach which examines fundamental assumptions of strategy and overall defence policy". Many intellectuals, however, have criticized the scope of their critiques, on the grounds that they too are formulated on far too limited a range of assumptions. Perhaps theirs is a kind of "critical-instrumental" research. Although the RAND Corporation is situated some 3,000 miles from the Pentagon, its influence is said to be significant; it is certainly large, affluent, and prestigious. In 1964 *Science* tried to determine its influence, and was able to report no more than that in some decisions its work had been influential, in others ignored[21]. Such influence as there was clearly depended on the capacity and willingness of the sponsor to utilize the work, and *Science* pointed out that this had resulted in the growth of a group of specialists, almost mirroring RAND, in the Air Force headquarters. What is more, it is argued that an important source of RAND influence has been through the alumnii who have subsequently entered government service. If this is so, then ideas move with men—a familiar concept.

If RAND and its fellows have been criticized for the instrumentality of their criticism, can a different kind of policy research be found in the universities? Science policy research is done in universities, in America of course, and in Europe too (for example Heidelberg, Lund and Sussex) although its necessary interdisciplinarity has made its accommodation difficult in some countries. Of course, sociologists would argue that attention to the immediate problems of policy makers can yield no professional reward, no recognition. So perhaps academic research must be of the most critical kind. Studying the attitudes and interests of both officials and academics concerned with science policy, La Porte[22] found a clear incongruity of interest between the two groups, which derived their interests in very different ways, one from theory, the other from practice. To put his findings into the language of this article, it could be said that the policy makers to whom he spoke were only interested in obtaining relatively limited instrumental research, and the academics were only interested in doing what would have been critical research if they had understood the policy making process adequately. La Porte suggests that academics should be allowed to spend periods of a few months working in relevant government agencies. Would they want to?

Where then do we stand? I have suggested that an instrumental kind of policy research can be influential and useful, provided it is taken up by some pre-existing interest group or, perhaps, if it is done by certain institutes with high prestige and their own special links to the decision-making structure. Academics are loath to do this kind of work. The same limitations apply to more fundamentally critical research, which must pose very difficult problems, and in this case the academics with both the interest and the understanding to do it are limited in number. If research of this kind is to be influential a good deal of thought must be given both to its organization and to ways in which it might be applied.

Interferon stimulated by Double Stranded RNA

by
T. C. MERIGAN
Division of Infectious Diseases,
Department of Medicine,
Stanford University,
Stanford, California 94305

Interferon represents an interesting approach to the control of viral disease in man and his domestic animals, as this review shows, for it is a part of the animal's own recovery processes during naturally occurring infection and active against most viruses that cause acute infection.

INTERFERON has become a topic of great medical and biological interest, for it is possible that careful analysis of this defence mechanism against viruses could be utilized to prevent the full expression of virus disease. In the decade since the discovery of interferon[1] by Isaacs and Lindemann many microbes and microbial extracts other than viruses have been observed to stimulate the production of this protein. But it was the polyanionic interferon inducers, particularly the most potent of them, double stranded nucleic acids, which raised the possibility of a modern molecular pharmacological approach to the utilization of interferon in human and animal disease. Although the double stranded RNAs are potentially economically feasible as drugs, their toxicity or other limitations may be prohibitive. This article, rather than being an exhaustive review of the rapidly growing literature on this topic, aims to evaluate this latter question.

Hilleman led the group at Merck Sharpe and Dohme that discovered the capacity of double stranded RNA to stimulate interferon[2-5]. This group and other groups have also pursued the other principal approach to the clinical utilization of the interferon mechanism—the preparation and purification of exogenous interferon. Because of the specificity of interferon, a preparation derived from primates would be required for humans. The short half-life of its activity in the blood means that large, presently impractical quantities of material derived from tissue culture or explants would be required. The instability of the biological activity of human interferon[6] has made this approach even more formidable. But important collaborative trials are in progress to determine the threshold amount of exogenous interferon required in man for the prophylaxis of several diseases[7].

There are some interesting implications of the potency of double stranded nucleic acid in the stimulation of the interferon. For example, it seems reasonable to expect that investigations of the action of these materials will lead to a better understanding of the natural mechanism by which viruses stimulate interferon in cells and whole animals. Also, this is a further function of nucleic acids, and the structural basis of this activity may have implications in nucleic acid structure and genetic function. Increasing knowledge of the genetic role of nucleic acids in the past two decades has produced an immense amount of chemical information about their structure and synthesis. The stimulation of interferon might be one way by which this information will be brought directly to bear on problems of human disease. In contrast to microorganisms or their extracts, double stranded synthetic nucleic acids have appeal for clinical use because they are not pathogenic not do they contain potentially dangerous adventitious contaminants. They are highly active, and so the small doses which must be used are not likely to be immunogenic. The fundamental question remaining is whether or not their side effects will limit their systemic use in man. There is a real need for a broad spectrum approach to viral control in the respiratory tract because of the vast number of agents causing disease in this region of the body. Because of the selectivity of action of most small molecule antiviral agents and the highly specific action of vaccines, the use of interferon, which is active against most of the viruses infecting this region[8], is particularly attractive. Here, treatment could be started or prophylaxis given before the specific infecting virus strain were identified.

Structural Requirements

The property of interferon stimulation is shared, although to a differing degree, by many synthetic and naturally occurring polyanions, including polyribonucleotides[2-5], plastics[9-12] and polysaccharides[13,14]. Similarities in the secondary structure of such diverse materials are suggested by the recent report that a sulphated seaweed polysaccharide which can stimulate interferon has a double helical structure, revealed by X-ray analysis[15]. A resemblance of these polyanions to viral nucleic acids is suggested by the finding that two of the active plastics, dextran sulphate and polyvinyl sulphate, as well as various nucleotide homopolymers can nucleate the assembly of the capsid proteins of plant viruses into particles closely resembling the original virus when examined under the electron microscope[16].

Double stranded ribonucleic acids with a high potency for interferon stimulation have been obtained from many sources, including fungal[2], bacterial[5], animal[4] and plant viruses. It is interesting that several preparations derived from *Penicillium*, which have previously shown antiviral activities in pharmaceutical screening programmes, owe much of their activity to their content of one or more serologically unrelated[17] double stranded RNA-containing mycophages[2,18]. A synthetic nucleic acid, that is the homopolymer pair (poly I : C) derived from annealing polycytidylic acid with polyinosinic acid, is among the most active[3] and readily available from several commercial sources. It is therefore the most widely studied compound in the series. But some twenty-seven other synthetic nucleic acids have also been studied for their ability to stimulate interferon or cellular resistance to virus infection, and so certain general conclusions are possible about structural requirements. RNA is much more active than any DNA[3,14,19], and double stranded molecules formed through complementary base pairing are much more active than one, three or four stranded molecules[3,14,19]. Double stranded complexes may form between two complementary homopolymers or through self-annealing of an alternating copolymer. Similar observations have

been made with naturally occurring RNA; for example, in contrast to the high activity of the double stranded replicative complex of MS–2 bacteriophage, the single stranded progeny virus is inactive[5].

Those homopolymer types which tend to form stable multi-stranded complexes have some activity in a highly sensitive tissue culture assay system[20]. These are polyinosinic acid, polyguanylic acid and polyxanthylic acid, and such aggregation can also be promoted with polyadenylic acid and polycytidylic acid by acidic or high magnesium conditions, which makes them somewhat active in tissue culture. There also seems to be requirement for a stable secondary structure of the double stranded complex because polymers with a low thermal stability seem to be less active than those with a higher thermal stability, that is a Tm greater than 60° C as measured in buffer containing 0·15 M sodium ion (review in ref. 14). For example, chemical modification like N_7 methylation, which lowers the stability of the double stranded complex found between polyinosinic and polycytidylic acids, decreases antiviral activity, whereas C_7 halogenation which does not effect stability does not influence activity (Gresser, I., personal communication).

It is not yet clear at what level this requirement for multi-strandedness and stable secondary structure acts; that is, it may be important in regulating the uptake of the RNA or in its interaction with a receptor site on or within the cell. But, as I shall discuss later, the most likely possibility is that multi-strandedness promotes the resistance of polymers to the ribonuclease in the cell as it does in the test tube. Double stranded RNA may account for the production of interferon by all mammalian viruses, for such material has been isolated from cells infected with either RNA or DNA virus[21,22], and even a virus irradiated with ultraviolet light has been reported to produce double stranded RNA as it stimulates interferon production[23]. It is possible, however, that the natural stimulation of viral interferon involves the synthesis or the location of single stranded RNA[24] at a critical site within the cell beyond the level at which the requirement for double strandedness acts.

The Stimulation Process

Radioactive materials have been used to investigate the sequence of interactions between interferon-stimulating RNA and cells[19,25]. The first step is adsorption to the cell surface. This is followed by a "recognition" step occurring at 37° C, which is a metabolic step within the cell, dependent on either the bulk of the RNA which is associated with membranes on the cell surface, or on the minute quantity of RNA which penetrates the cell[25], presumably in phagocytic vacuoles. The RNA is known ultimately to be degraded by the cells, and its components re-utilized in host RNA synthesis[25], but the recognition step is followed immediately by the production of interferon. The effects of metabolic inhibitors on this interferon production are quite complex; certain doses of agents inhibiting RNA or protein synthesis actually increase the amount of interferon produced by cells[26,27]. Such findings have led to the postulation of complex mechanisms of control, including a two-stage "synthesis and activation" mechanism[28] or a mechanism involving the synthesis of an inhibitor of interferon formation[29] within the cells concerned. Whether the production of interferon is through *de novo* synthesis or release of preformed material is a point of controversy requiring further study. Cells producing interferon are resistant to virus infection, and after the production step, there is a resistance to re-stimulation ("tolerance")[28] which may be related to the mechanism which turns off the initial response[29,30]. Both the protective effects and this tolerance phenomenon are transient in cells, both *in vitro* and *in vivo* lasting only a few days.

Potentiation of RNA Stimulation

Certain cell lines do not produce interferon when exposed to synthetic nucleic acids alone; they must be exposed to polycations at the same time, particularly DEAE-dextran[31] or neomycin[32]. These polybasic substances have been observed to increase the uptake of RNA by cells and also, by forming complexes, they may cause resistance to ribonuclease degradation within cells[25,33]. They have been reported[32] to act with single homopolymer species as well as double stranded complexes. Unfortunately, this type of potentiation is not consistently effective *in vivo*[34,35].

Awareness of the mechanism of interaction of cells with RNA has led to the development of several other methods for potentiating the interferon stimulating activity of RNA (Table 1). I have mentioned certain metabolic inhibitors which potentiate interferon levels *in vivo* or *in vitro* when dose and timing of administration are carefully controlled. A complex of fungal polysaccharide and RNA has been isolated which is said to contain only single stranded RNA[36]. It also seems to be an example of RNA potentiation, for the components of the complex are inactive alone and the complex appears to be resistant to degradation by ribonuclease in contrast to its susceptible RNA component.

Table 1. APPROACHES TO POTENTIATION OF INTERFERON STIMULATING ABILITY OF POLYNUCLEOTIDES

	Activity shown	Suggested mechanism
Polycations (DEAE-dextran, neomycin)	*In vitro* and inconsistently *in vivo*	Increased binding or ribonuclease resistance through complex formation
RNA-polysaccharide complexes	*In vitro* and *in vivo*	Protection from ribonuclease
Thiophosphate analogues	*In vitro* and *in vivo*	Protection from ribonuclease
Heating of alternating copolymers to 38° C	*In vitro* only	Protection from ribonuclease
Freund's adjuvant	*In vivo* only	Increased uptake of polynucleotide by interferon producing cells
Cycloheximide or actinomycin	*In vitro* and *in vivo*	Interferes with turnoff of interferon production mechanism

Two other methods for potentiating the production of interferon have been described. Both are apparently a consequence of increasing resistance of RNA to nuclease. One of these methods is the replacement of phosphate with thiophosphate in the backbone of the RNA molecule, which causes an increase of several orders of magnitude in the resistance to nuclease and the capacity to produce interferon[37]. This potentiation can be demonstrated both *in vivo* and in tissue culture. It may be of clinical significance as a useful molecular manipulation, particularly in the light of a report of an activity in animal sera which destroys the biological activity of poly I:C[38] but does not destroy the thiophosphate analogues as rapidly (unpublished work of De Clercq, E., Eckstein, F., Sternbach, H., and myself). In the second of these approaches to potentiation, nuclease resistance is achieved by a heat-induced configurational change in polymers in which two complementary bases alternate with each other[39]. A highly branched base paired complex seems to be converted into a linear fully base paired double stranded molecule, which removes sites for potential degradation by endonucleases. This potentiation can be shown best in tissue culture (and only to a much smaller extent *in vivo*), and is interesting primarily because it reinforces the idea, suggested by the

thiophosphate RNA analogues, that cellular nucleases compete with the interferon triggering site for polymers.

Another method potentiating the production of interferon involves the use of Freund's adjuvant (unpublished work of De Clercq, E., Nuwer, M., and myself). This mixture of mycobacterial extract and oil increases interferon after *in vivo* injection either of endotoxin or of the double stranded nucleic acids. The mechanism of this increase is obscure, however, although it is likely to involve increased reticuloendothelial function in processing and uptake of the RNA. Another method for potentiation of interferon production by endotoxin *in vivo* involves the injection of lead acetate, but unfortunately there is a parallel enhancement of the lethal effects of endotoxin (Stinebring, W. R., and Absher, M., personal communication).

Polyanion Effects in Animals

Knowledge of the interferon stimulating capacities of these double stranded nucleic acids has increased interest in their adjuvant effect in priming antibody production[40,41] (Table 2). They have also been reported to promote phagocytosis[42] and cell mediated immunity[43,44]. In addition to this broad range of effects on host defences, this class of compounds has been reported to have various side effects disturbingly similar to those seen with bacterial endotoxin[45], including pyrogenicity[46] and embryotoxic effects[47] as well as tumour necrotic effects[48] (which will be discussed later). A condition resembling runt disease has also been produced in mice with several types of double stranded RNA, including polyinosinic-polycytidylic acid[49].

Table 2. RANGE OF EFFECTS OF POLYANIONS

Agents against which polyanions are active	Diverse biological effects of polyanions
Numerous RNA or DNA viruses (both cytocidal and oncogenic)	Interferon stimulation
Bedsonia (trachoma)	Adjuvant effect on antibody production
Protozoa (*P. berghei*, *T. gondi* and *L. donovani*)	Accelerated cell-mediated immunity
Bacteria (*L. monocytogenes*, *E. coli*, etc.)	Macrophage "activation"
Fungus (*C. neoformans*)	Anti-complement activity
Tumours	Pyrogenicity

Several animal model virus infections have been explored with naturally occurring or synthetic double stranded RNA (poly I : C) prophylaxis. In most cases the results have been favourable. Notable exceptions have been the slow virus, scrapie[50], which was not influenced by a fungal double stranded RNA preparation and the so-called NZB disease of mice (an autoimmune disease thought to be initiated or intensified by a virus) which seems to be worsened by treatment with poly I : C [51]. Many favourable results have been reported in animal model systems which resemble human disease: for example, influenza, vaccinia and Columbia SK (caused by a polio-like virus) in the mouse[52,53] and rabies[54] (also B. Janis and K. Habel, personal communication) and herpes simplex[55] in the rabbit. In the latter infection and in an encephalitis in mice due to vesicular stomatitis virus (VSV)[56] favourable results have been reported even if the administration of RNA is delayed until after virus replication has reached a peak in the target organ. These results give some hope that therapeutic effects will be achieved in man. In all these models the challenge doses may be much greater than in man, but the routes of infection and the pathogenesis of the disease seem to resemble their human counterparts. It is encouraging that there was a 200-fold margin of difference between the lowest protective dose and the toxic dose in the mouse-VSV models[56]. The timing, dosage and route of inoculation of the RNA are critical in determining the results and must be adjusted, depending on the particular virus model under study.

Inhibitory effects with polyanionic interferon stimulators have also been seen in *in vivo* models of protozoa[57] and trachoma[58] infections. Such results are not surprising, for interferon is active against these agents. On the other hand, in very few animal model systems has interferon been directly implicated in the protective effect. When the blood concentrations of interferon produced by intravenous poly I : C are stimulated with passively administered interferon obtained in tissue culture, protective effects can be observed in the mouse-VSV model similar to those seen with the corresponding dose of poly I : C (unpublished work of De Clercq, E., Nuwer, M., and myself).

Protective effects with double stranded RNA have also been reported against bacteria and fungi (refs. 59 and 60 and Weinstein, M., Waitz, J., and Came, P., personal communication), as well as certain tumours[48,61] not known to be dependent on continued virus replication, including both chemically and viral induced standard laboratory tumour lines, as well as certain spontaneously acquired neoplasms. Here, it is likely that other effects of the polyanions mediate the inhibitory action, including the endotoxin-like side effects, as well as the stimulatory effect on cell-mediated immunity, although crude interferon has suppressed certain non-viral tumours[62]. Interferon itself seems to be most potent against RNA virus tumours such as the mouse leukaemias[63,64] where the continued reinfection of cells may be critical in maintaining the progression of the tumour. Lesser effects, however, are seen with the DNA tumour viruses where transformed cell growth[65,66] seems critical rather than continued rounds of infection and transformation. It is significant that single stranded nucleic acids have been observed to have anti-tumour effects, which suggests that other, most likely immunological, effects of polyanions are involved[67].

Potential for Human Diseases

The principal rationale for the use of interferon in human virus infections comes from the fact that viruses which stimulate interferon suppress the development of certain virus infections in man[68–70]. These results, however, have been obtained in prophylactic rather than therapeutic studies, and because the bulk of virus replication occurs early in the disease process in most virus infections, it is clear that interferon, like all types of antiviral agents, is more effective in prophylaxis than therapy.

A major unanswered question is whether tolerance to repeated interferon stimulation will be a problem. As the requirement for prophylaxis might be quite prolonged, continued stimulation of the system would be desirable. Within a narrowly defined range of "partial" stimulation, this is apparently possible[28,71]. In contrast to the lack of complications with local therapy, systemic administration of double stranded RNA to animals has produced various toxic effects. Many such effects, however, have been reported without concomitant examination of antiviral activities or any physical characterization of the polynucleotide preparations used. So far, trials with humans have indicated that interferon can be stimulated in the absence of striking toxic effects, although fever and slight changes in liver, haematopoietic and blood clotting parameters have been observed.

Clinical studies have been conducted to evaluate the anti-tumour properties of these compounds[72,73], and it

is not clear what their effects will be on humans with serious acute systemic infection. There may be some cross-tolerance with the infecting virus so that little or no further augmentation of the host interferon response is obtained. It is apparent therefore that after a proper period of experimentation with animals, the questions involving poly I : C efficacy against human virus infections must be answered in carefully conducted clinical trials in humans with virus infections. Ultimately, we must know the therapeutic ratio (the ratio of antiviral activity to the toxic activity) in man, for marked differences in toxicities have been observed from species to species. This ratio also depends on the nature and stage of the infection under treatment, as well as the route of drug administration. It is likely that, as usual with clinical investigation, work will begin with the serious diseases where the patient has the most to gain from any useful effects to balance the dangers inherent in the new drug. Humans with cancer will be early candidates for this material, in spite of the lack of evidence of permanent tumour eradication in any of the animal models. On the other hand, local treatment of the respiratory tract has the obvious advantage of minimal systemic side effects, and encouraging prophylactic antiviral effects have been noted against a rhinovirus in human volunteers[72]. But once the infectious process has developed in the respiratory tract, delivery of the inducer to the involved local areas for therapy seems to be difficult, and so uses seem to be limited to prophylaxis. New interferon stimulators under consideration as clinically useful alternatives to double stranded RNA include polyanions derived from partially oxidized starch[74] and the small synthetic molecule, DEAE-fluoronone, which is active orally[75]. But at this point it seems that only further empirical investigation will show whether the interferon stimulating capacity or other effects on host defences of the double stranded RNAs can be used in the control of human infections (see also reviews[76–84]).

The enzyme involved in the discontinuous replication of DNA seems not to be the Kornberg polymerase but to be associated with the membrane.

STUDIES in this and other laboratories[1–18] support the idea that one or both strands of DNA are synthesized *in vivo* in a discontinuous fashion, whereby short DNA segments are synthesized in the 5′→3′ direction and subsequently connected by ligase. In the T4 system, both strands seem to be synthesized discontinuously[4].

It was originally postulated that the short DNA chains may be synthesized by DNA polymerase[2]. Although the exclusive synthesis of the short chains in the 5′→3′ direction (refs. 5, 17 and 18 and A. S. and R. O., manuscripts in preparation) conforms to this notion, certain other aspects of *in vivo* DNA synthesis disclosed by our studies are difficult to reconcile with the known properties of DNA polymerase. (1) Whereas two strand-discontinuous replication needs frequent initiation of synthesis of new chains along two template strands, DNA polymerase cannot carry out *de novo* chain initiation[19]. (2) The rate of elongation of the T4 short chains is estimated to be a few thousand nucleotides per second at 37° C (refs. 17 and 18, A. S. and R. O., manuscripts in preparation). The chain elongation rate in the *in vitro* DNA polymerase reaction, however, is at most 10 to 20 nucleotides per second at 37° C (ref. 20). (3) There is no indication that DNA polymerase synthesizes DNA chains of discrete sizes similar to the *in vivo* nascent short DNA chains.

These considerations led us to begin a serious search for a DNA synthesizing activity distinct from that of DNA polymerase. Initial work with *E. coli* ER22 (endonuclease I⁻) showed that the "membrane fraction" isolated by gentle lysis[21] synthesizes "short DNA chains" similar to the *in vivo* nascent short DNA chains. The isolation of a mutant of *E. coli* (P3478) which has little DNA polymerase activity[22] prompted us to examine this organism for DNA synthesizing activities, particularly the *in vitro* activity apparently associated with the membrane. A spontaneous *thy*⁺ revertant from *E. coli* P3478 *thy*⁻ (*polA*1), referred to as *polA*1′, and the parent strain W3110 *thy*⁻, referred to as *polA*1⁺, were used. The results obtained suggest strongly that a DNA synthesizing activity which is distinct from DNA polymerase and which is associated with the membrane carries out synthesis of the short DNA chains in the discontinuous mode of replication. Since the completion of this work there have been two reports of *in vitro* DNA synthesizing systems in *polA*1 or its derivative[23,24].

Discontinuous Synthesis of DNA by *Pol*A1

We first examined *polA*1′ for the newly synthesized short DNA chains that are found in wild-type cells.

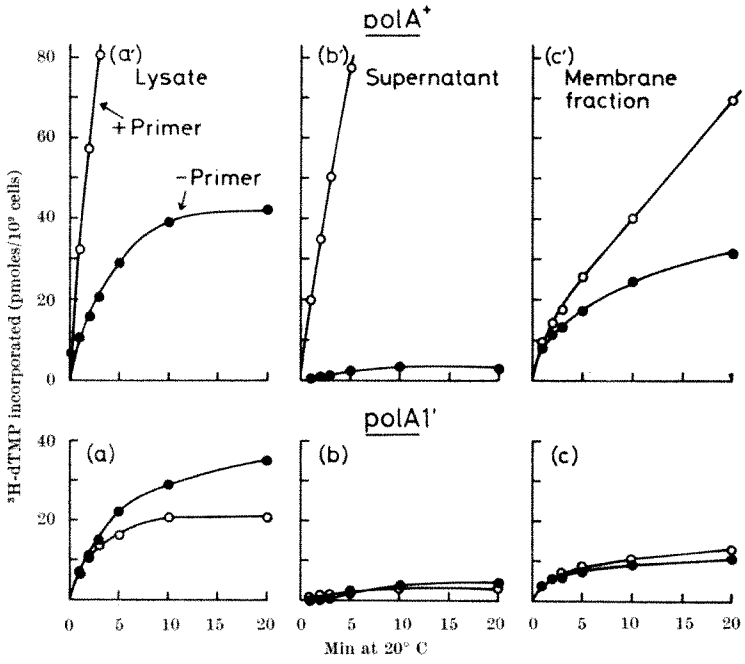

Fig. 1. DNA synthesis by "lysate", "supernatant" and "membrane fraction" of *polA*⁺ and *polA*1′. "Lysates" were prepared from a 40 ml. culture of *polA*⁺ and *polA*1′ grown in tryptose broth at 37° C to 6×10^8/ml. Cells were harvested by centrifugation, washed with 0·01 M Tris (*p*H 8·0) and suspended in 0·8 ml. of 25 per cent sucrose–10 mM Tris (*p*H 8·0)–1 mM EDTA. After addition of 0·2 ml. of a lysozyme solution (2 mg/ml. in 0·25 M Tris (*p*H 8·0)) the suspension was incubated at 0° C for 1 min, mixed with 1 ml. of a lytic mixture consisting of 1 per cent 'Brij 58', 2 mM Tris (*p*H 7·3) and 30 mM $MgSO_4$ and immersed in an ice bath for 5 min. The "lysate" was centrifuged at 6,000*g* for 5 min to yield the "supernatant". To isolate the "membrane fraction", 7 ml. of 20 mM Tris (*p*H 8·0)–15 mM $MgSO_4$ were added to 2 ml. of lysate. The mixture was placed on 0·2 ml. of 20 per cent sucrose–20 mM Tris (*p*H 8·0)–15 mM $MgSO_4$ and centrifuged at 6,000*g* for 5 min. The pellet was suspended in 2 ml. of 20 mM Tris (*p*H 8·0)–15 mM $MgSO_4$. Reaction mixtures (200 μl.) for DNA synthesis contained 17 mM Tris (*p*H 8·0), 12 mM $MgSO_4$, 200 μM rATP, 100 μM dATP, dGTP and dCTP, 10 μM ³H-dTTP (0·3 Ci/mmole), 0·13 mM yeast tRNA and 100 μl. of lysate, supernatant or membrane fraction. Where indicated 50 mM "activated" and denatured salmon sperm DNA[25] was added as "primer". The reaction was carried out at 20° C and terminated by cold TCA. Acid-insoluble radioactivity was counted.

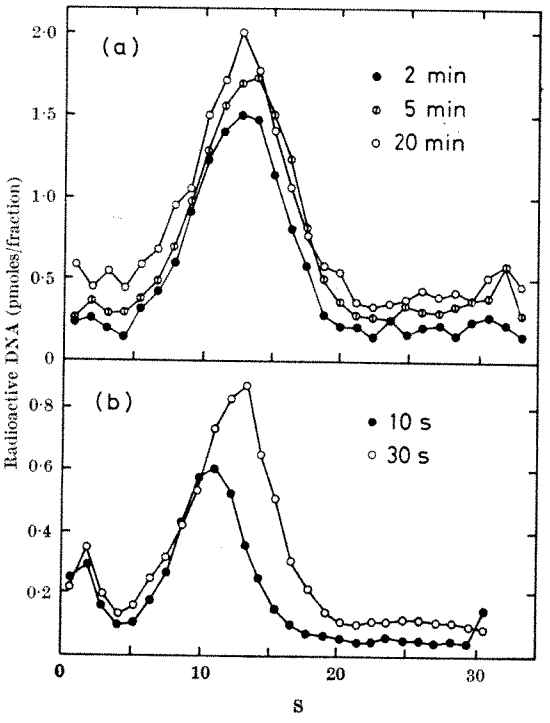

Fig. 2. Alkaline sucrose gradient sedimentation of DNA synthesized by the *polA1′* membrane fraction. The reaction mixtures (200 μl.) were as in Fig. 1 except that 10 μM ^{3}H-dATP (1·6 Ci/mmole) and 10 μM ^{3}H-dTTP (12 Ci/mmole) were used as labelled substrate in *a* and *b* respectively and the other deoxynucleoside triphosphates added at 100 μM. No primer DNA was added. Incubations at 20° C were terminated by chilling, and the addition of 0·2 ml. of 0·4 N NaOH–40 mM EDTA–1 per cent sodium N-lauroyl sarcosinate. The mixtures were incubated at 37° C for 20 min and sedimented through alkaline sucrose gradients for 21 h at 27,000 r.p.m. and 4° C in a Spinco SW27 rotor. The amount of radioactive DNA, in pmoles of total nucleotide residues, was calculated assuming that the mole fraction of A and T is 0·25 respectively.

Growing cells of *polA1′* were exposed to ^{3}H-thymidine at 30° C for various periods and the labelled DNA was analysed by alkaline sucrose gradient sedimentation. A large portion of DNA labelled by short pulses (5 to 12 s) sedimented at an average rate of 10 to 11S. Increasing the pulse time caused increases in the sedimentation rate of the labelled DNA. After neutral sucrose gradient sedimentation of the labelled DNA that had not been subjected to denaturation, 47, 21 and 19 per cent of the radioactivity was found in a DNA component sedimenting at about 15S after 5, 12 and 30 s pulses, respectively. Furthermore, comparable portions of the labelled DNA (45, 34 and 22 per cent after 5, 12 and 30 s pulses, respectively) were susceptible to *E. coli* exonuclease I. All these results are similar to those obtained previously using other *E. coli* strains[1,2]. Thus *polA1′* seems to synthesize DNA *in vivo* by the same discontinuous mechanism as wild-type *E. coli*.

Membrane and Supernatant DNA Synthesis

Sonic extracts of *polA1′* had almost no DNA polymerase activity (less than 1 per cent of the activity found in *polA*$^+$ extracts) when assayed using various primers. Lysates prepared from *polA1′* cells, however, by treatment with lysozyme–EDTA and 'Brij 58' (ref. 21), as well as lysates of *polA*$^+$, had an activity that catalyses the incorporation of the radioactivity from ^{3}H-dTTP or ^{3}H-dATP into DNA in the presence of the other three deoxynucleoside triphosphates and rATP (Fig. 1*a*, *a′*). In the absence of added primer DNA, the lysates of *polA1′* and *polA*$^+$ exhibited almost the same level of incorporation. The rate of incorporation in the lysates of both strains declined quickly during incubation. The addition of primer DNA greatly enhanced the incorporation in the *polA*$^+$ lysate but slightly inhibited the incorporation catalysed by the *polA1′* lysate.

When the "supernatant" and the "membrane fraction" were prepared from the *polA1′* lysate by low-speed centrifugation, about half of the activity (as well as more than 95 per cent of the nascent and bulk DNA) was recovered in the membrane fraction (Fig. 1*c*). About 10 per cent of the activity was found in the supernatant (Fig. 1*b*). A large portion of the activity of the *polA*$^+$ lysate, apparent only on addition of primer, was recovered in the supernatant (Fig. 1*b′*). The rest of the activity of *polA*$^+$ lysate was recovered in the membrane fraction and was weakly stimulated by the primer presumably because of the contaminating supernatant activity (Fig. 1*c′*). In the absence of added primer, more activity was found in the membrane fraction than in the supernatant as in *polA1′*.

The DNA synthesizing activity of our *polA1′* membrane fraction is similar in its general properties to that of the membrane-associated DNA synthesizing systems of Smith *et al.*[23] and Knippers and Strätling[24], which were prepared differently.

In our *polA1′* membrane fraction system the reaction levelled off as quickly as the reaction catalysed by the whole lysate (Fig. 1*c*) and did not require exogenous DNA. It was abolished by omission of any of the four deoxynucleoside triphosphates and was halved by omission of rATP. It was little affected by replacement of the three unlabelled deoxynucleoside triphosphates with the corresponding diphosphates. Pyrophosphate (100 mM) but not orthophosphate (10 mM) inhibited the reaction, however, suggesting that the triphosphates are the direct precursor of DNA. The incorporation of ^{3}H-dTTP was greatly reduced by the addition of a ten-fold excess of unlabelled dTTP or dTDP but was not affected by unlabelled dTMP or thymidine. The reaction was not inhibited by either KCN (4 mM) or nalidixic acid (50 μg/ml.), but was inhibited almost completely by *p*-chloromercuribenzoate (10^{-5} M), which has little effect on *E. coli* DNA polymerase.

Short DNA Chains of a Discrete Size

The radioactive DNA synthesized by the *polA1′* membrane fraction pelleted along with the membrane when the reaction mixture was centrifuged at 6,000*g* for 5 min, indicating that the product DNA associates with the "membrane". If the reaction mixture incubated for 1 min at 20° C was treated with sodium N-lauroyl sarcosinate and then centrifuged, the labelled DNA was recovered in the supernatant. Whereas about 60 per cent of the radioactive DNA sedimented rapidly (more than 80S) in a neutral sucrose gradient containing SSC, about 40 per cent of the DNA was recovered in a component sedimenting at about 20S. Thirteen per cent of the synthesized DNA was susceptible to exonuclease I after extraction by the Thomas procedure. These properties of the DNA synthesized by the membrane fraction resemble those of the *in vivo* nascent DNA.

Fig. 2 shows the profile of an alkaline sucrose gradient sedimentation of DNA which was synthesized by the *polA1′* membrane fraction during various periods of incubation. After 10 s incubation at 20° C, most of the labelled DNA sedimented at an average rate of 10·5S. The DNA synthesized during an incubation of 30 s mostly sedimented as a band with an average sedimentation coefficient of 12·5S. Although the synthesis did continue after 30 s, increasing the incubation time beyond 30 s did not change the size of the DNA. When the membrane fraction prepared from cells which had been exposed to ^{3}H-thymidine for 15 s at 20° C or 10 min at 37° C was incubated with unlabelled substrates for a further 20 min, virtually no change was found in the size and amount of the labelled DNA. These results suggest that these *in vitro* short chains are not products of endonucleolytic

degradation. The *polA*1′ membrane fraction seems to have an ability to synthesize short DNA chains of a discrete size (about 12·5S). This is close to but a little larger than the size of the *in vivo* nascent short DNA chains of *E. coli* (10 to 11S), which may represent an average size of growing and completed short chains in the steady-state conditions. The number of short chains produced by the *polA*1′ membrane fraction *in vitro* during a 2 min incubation at 20° C is about ten per cell if *de novo* synthesis of these chains is assumed.

DNA Synthesis in T4 infected *polA*1′

DNA synthesizing activity associated with the membrane fraction of *polA*1′ disappeared rapidly on infection of the cell with T4 *am* B22 (gene 43), a DNA polymerase mutant (Fig. 3*a*). The disappearance of the activity of the membrane fraction was also observed after infection with another DO mutant, T4 *am* N82 (gene 44), which induces phage DNA polymerase (Fig. 3*b*). On infection with T4 *r*II (EM7) as well as T4D (wild type), the DNA synthesizing activity of the membrane fraction also decreased, but this was followed by a sharp increase (Fig. 3*c*). Thus after T4 infection, the DNA synthesizing ability of the *polA*1′ membrane fraction changes in parallel with the DNA synthesis *in vivo*.

The activity associated with the membrane fraction of T4D or T4 *r*II-infected cells was basically similar to that of the membrane fraction from uninfected cells. The reaction (assayed by ^{3}H-dTTP incorporation), requiring the presence of four deoxynucleoside triphosphates, was slightly stimulated by rATP, levelled off shortly after onset, and was not affected by the addition of thymidine, dTMP, KCN or NaN_3. The synthesized DNA was of a discrete size (8 to 9S), but was distinctly smaller than the short DNA chains synthesized by the membrane fraction from uninfected cells (12·5S). This is similar to the size difference between *in vivo* nascent short DNA chains of T4 (8 to 9S) and *E. coli* (10 to 11S) (refs. 2, 3, 6). It is worth noting that there is little indication of endonucleolytic degradation of these short chains during the period between the first and tenth minute of incubation. T4 *r*II was used in these experiments, for the *r*II mutation presumably suppresses the synthesis or the function of a T4 endonuclease. Similar results were obtained with T4D.

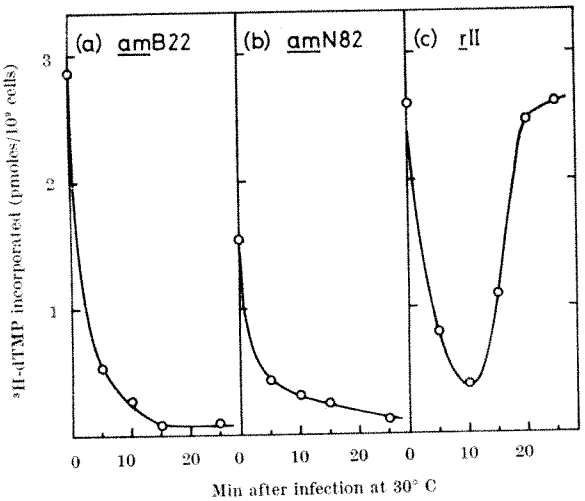

Fig. 3. Changes of DNA synthesizing activity of the *polA*1′ membrane fraction after T4 infection. Cells were grown to 6×10^8/ml. at 30° C in medium *A* (ref. 2) supplemented with 0·5 per cent casamino-acids and infected with the indicated strains of T4 (m.o.i. = 10). Samples (20 ml.) were taken at various times after infection and cells were collected by centrifugation. The "lysate" was prepared as described in Fig. 1 except that cells were not washed before lysozyme treatment. The "membrane fraction" was prepared from the lysate as described in Fig. 1 and washed once in 20 mM Tris (*p*H 8·0)–15 mM $MgSO_4$. The reaction was carried out in a 250-μl. incubation mixture as in Fig. 1 for 2 min at 20° C with 160 μl. of the membrane fraction and ^{3}H-dTTP with a specific activity of 0·15 Ci/mmole.

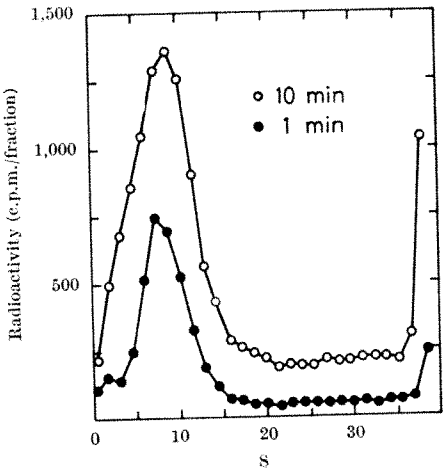

Fig. 4. Alkaline sucrose gradient sedimentation of DNA synthesized by the membrane fraction of T4 *r*II-infected *polA*1′. The membrane fraction was prepared as described in Fig. 3 from cells at 25 min after infection at 30° C. The reaction was carried out as in Fig. 2 using 160 μl. of the membrane fraction and ^{3}H-dTTP with a specific activity of 12 Ci/mmole. An equal volume of 0·4 M NaOH–40 mM EDTA–1 per cent sodium N-lauroyl sarcosinate was added and the mixture was incubated at 37° C for 20 min and sedimented through alkaline sucrose gradients for 22 h at 25,000 r.p.m. and 5° C in the 'SW25·3' rotor.

The ^{3}H-DNA synthesized by the membrane fraction of T4 *r*II-infected *polA*1′ annealed efficiently with T4 DNA, whereas little hybridization was observed with *E. coli* DNA. Thus in a typical experiment, 78·8 per cent of the input ^{3}H-DNA annealed with T4 DNA (4 μg), whereas only 7·4 per cent annealed with *E. coli* DNA (20 μg). The ^{3}H-DNA, like *in vivo* T4 nascent short DNA chains[4], annealed equally to both of the separated complementary strands of T4.

DNA Chain Synthesis *de novo*

It is possible that the reaction catalysed by the membrane fraction represents only the addition of some nucleotides to the 3′ termini of the *in vivo* nascent short chains present in the membrane complex. To test this the following experiment was performed. The *polA*1′ membrane fraction was allowed to incorporate ^{3}H-dTTP for 1 min at 20° C in the standard reaction mixture. DNA was extracted and sedimented on alkaline sucrose gradients. The labelled 12·5S DNA was then subjected to successive treatment with spleen deoxyribonuclease II and spleen phosphodiesterase followed by 'Sephadex' gel filtration. This procedure[17], which will be described in detail elsewhere, permits the selective isolation of the 5′-phosphoryl terminal portion of DNA chains as large oligonucleotide fragments. The results shown in Fig. 5*a* indicate that approximately five per cent of the radioactivity of the DNA was recovered in the oligonucleotide fragments, which were eluted from the column with the void volume. If this material was treated directly with spleen phosphodiesterase a second time, almost no degradation was observed (Fig. 5*b*). The same material was degraded to mononucleotides, however, if it was treated with bacterial alkaline phosphatase before the treatment with spleen phosphodiesterase (Fig. 5*c*). ^{3}H label must therefore be in the 5′-phosphoryl terminal portion of the 12·5S DNA. It is thus unlikely that the incorporation catalysed by the membrane fraction represents only the addition of nucleotides to the 3′ termini of preformed *in vivo* nascent short DNA chains of nearly completed sizes. The results suggest, though do not prove, that the *polA*1′ membrane fraction may carry out *de novo* synthesis of these short chains. The possibility that the synthesis might proceed in the 3′→5′ direction has not been excluded, although this seems remote, because *in vivo* DNA synthesis (as

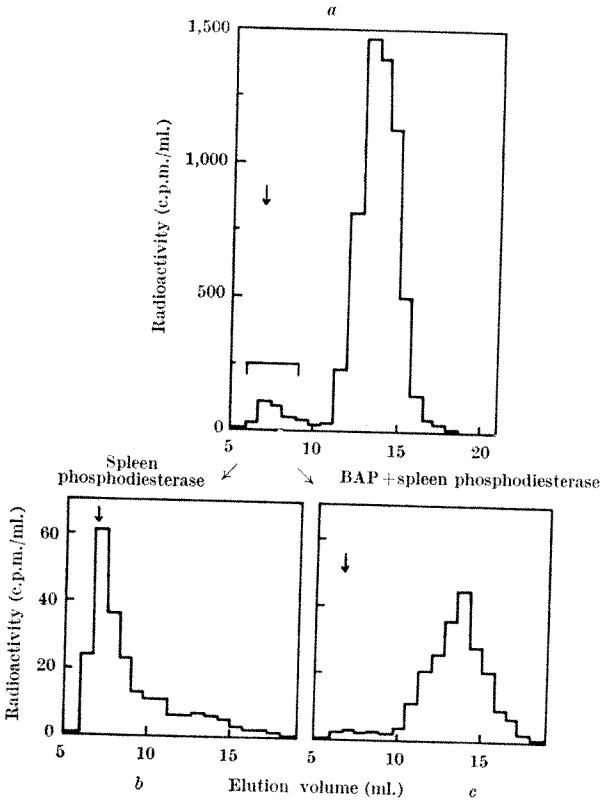

Fig. 5. Isolation of the 5′-phosphoryl termini of ^{3}H-labelled DNA synthesized by the membrane fraction as radioactive oligonucleotide fragments by treatment with spleen deoxyribonuclease II and phosphodiesterase followed by 'Sephadex' gel filtration. The *polA1′* membrane fraction (1·6 ml.) was incubated with ^{3}H-dTTP (12 Ci/mmole) in the standard conditions at 20° C for 1 min. The labelled DNA was pelleted along with the membrane by centrifugation at 7,000*g* for 10 min, extracted by the modified Thomas method[3], treated with 50 μg/ml. pancreatic ribonuclease in SSC, denatured in 0·1 M NaOH–10 mM EDTA, and sedimented through an alkaline sucrose gradient. (*a*) The peak fractions (average 12·5S) were pooled and treated with hog spleen deoxyribonuclease II at 37° C for 30 min in a 1·8 ml. reaction mixture containing 0·1 M sodium formate (*p*H 4·5) and 40 units of enzyme. After heating at 80° C for 10 min, the DNA was further digested with bovine spleen phosphodiesterase at 37° C in a 2·4 ml. reaction mixture containing 0·1 M potassium phosphate (*p*H 7·6), 100 μM d–pTp and 9 units of enzyme. After 6 h, 9 units of enzyme were added and the incubation continued for 6 h. The sample was applied together with blue dextran 2,000 to a 'Sephadex G-25' column (0·8 × 35 cm) and eluted with 0·1 M NaCl–1 mM Tris (*p*H 8·2). The arrow indicates the void volume. (*b*) The bracketed fractions of (*a*) were combined, concentrated, added to a 'Sephadex G-25' column and eluted with 0·01 M NaCl–1 mM Tris (*p*H 8·2). One portion of the sample was treated with spleen phosphodiesterase as in (*a*) in a 0·9 ml. reaction mixture with 4 units of enzyme and subjected to 'Sephadex G-25' gel filtration. (*c*) The other portion of the excluded material was treated with bacterial alkaline phosphatase (BAP) at 37° C in a 1·1 ml. reaction mixture, containing 10 mM Tris (*p*H 8·2) and 10 μg of enzyme. After 30 min 10 μg of enzyme was added and incubation was continued for 30 min. The BAP-treated sample was then digested with spleen phosphodiesterase as in (*a*) in a 1·3 ml. reaction mixture with 6 units of enzyme and subjected to 'Sephadex G-25' filtration.

well as all the known enzymic reactions for polynucleotide synthesis) occurs in the 5′→3′ direction. Experiments to clarify this point are in progress.

When duplex DNA with nicks is used as primer, *E. coli* DNA polymerase catalyses "nick translation", by concurrent 5′→3′ exonucleolytic degradation and 5′→3′ chain elongation[19]. The possibility that the reaction catalysed by the membrane fraction is of this type was considered seriously, for discontinuities exist in the nascent portion of DNA which is presumably attached to the membrane[26,27] and residual DNA polymerase might also be there. Two observations suggest, however, that this is not the case. The membrane fraction was isolated from *polA1′* cells which had been exposed to ^{3}H-thymidine (12 s at 30° C) to label nascent DNA chains totally and incubated in standard conditions for DNA synthesis with unlabelled deoxynucleoside triphosphates. During 1 to 5 min of incubation virtually no degradation of the labelled nascent chains (less than 1 per cent of the synthesis) was found. The *polA1′* membrane fraction was incubated in a standard reaction mixture with ^{3}H-dTTP for 30 s at 20° C. Further synthesis in the presence of a fifty-fold excess of unlabelled dTTP did not decrease the label in the short DNA chains.

DNA Synthesis by the Lysate

About a half (30–60 per cent) of the activity in the lysate of *polA1′* was recovered in the membrane fraction and a small portion (about 10 per cent) in the supernatant (Fig. 1). The unfractionated lysate may contain additional activity compared with the membrane fraction. After incubation for 1 min with the *polA1′* lysate, two sizes of products were found. In addition to a slowly sedimenting component comparable in size with that produced by the membrane fraction (13S in alkali), there was a component sedimenting at an average rate of 31S. Pulse-chase experiments indicated that the 13S component is not a precursor of the 31S component. But in similar experiments with lysates of T4 *r*II-infected *polA1′* most of the incorporated label was found in an 8 to 9S component and there was no indication of a fast sedimenting product with a discrete size. These results might be related to the recent findings suggesting that in bacteria only one of the two DNA strands may be synthesized discontinuously. Nascent short DNA chains of *B. subtilis* anneal almost exclusively to the "L" strand[28,29]. Iyer and Lark[30] found that a half of the pulse label incorporated into *E. coli* DNA was present at the 3′ ends of long DNA chains.

We thank Dr John Cairns for providing us with his mutant and Dr Nicholas Cozzarelli for helpful discussion. This work was supported by grants from the Ministry of Education of Japan, the Jane Coffin Childs Memorial Fund for Medical Research and the Takeda Science Foundation.

New RNA Polymerase from *Escherichia coli* infected with Bacteriophage T7

by
MICHAEL CHAMBERLIN
JANET McGRATH
LUCY WASKELL

and Virus Laboratory,
University of California,
Berkeley, California 94720

A new T7-specific RNA polymerase is found in T7 phage-infected cells. It is the product of T7 gene 1 and is physically and biochemically distinct from the host cell RNA polymerase. The synthesis of T7 RNA polymerase provides a direct explanation for the pleiotropic control of late T7 functions exerted by gene 1.

THE growth of a bacteriophage in a bacterial cell provides a useful system for the study of the regulation of gene expression. In the case of several bacteriophages of *Escherichia coli*, regulation of gene expression seems to occur at the level of transcription; only messenger RNA species containing information for early bacteriophage proteins are formed early in infection. At the appropriate time, one or more "switching" events occur which trigger the synthesis of messenger RNA for late bacteriophage genes (for reviews, see refs. 1, 2) and which terminate the transcription of some early bacteriophage genes. It has been proposed that the change in transcription specificity leading to synthesis of late messenger RNA is provided in bacteriophages T4[3] and T7[4] by synthesis of a new protein component, which functions in place of the sigma subunit of *E. coli* RNA polymerase and which allows the host cell RNA polymerase to initiate RNA synthesis at promoter sites for late bacteriophage genes, where it otherwise would not function. We show here that bacteriophage T7 induces the formation of a new RNA polymerase activity in infected *E. coli*. The T7 RNA polymerase is distinct from *E. coli* RNA polymerase and seems to be the protein product of gene 1 of T7 bacteriophage. Synthesis of messenger RNA for late bacteriophage functions seems to be mediated by this phage-induced RNA polymerase and not by an alteration of the host RNA polymerase.

Procedures

^{3}H-labelled and unlabelled nucleotides were obtained from Schwarz Bioresearch; α-^{32}P-ATP was prepared by the method of Symons[5]. DNA from T2, T7 and λ bacteriophages was prepared according to Thomas and Abelson[6]. dAT copolymer and dG·dC homopolymer pairs were prepared according to Schachman *et al.*[7] and Radding *et al.*[8], respectively. DNA concentrations are expressed in terms of nucleotide equivalents. Rifamycin was the gift of Ciba Pharmaceuticals, and streptolydigin was donated by the Upjohn Co. Gel electrophoresis was carried out according to Shapiro *et al.*[9] using *E. coli* RNA polymerase to provide molecular weight standards[10]. *E. coli* RNA polymerase was purified by the procedure of Berg *et al.*[11] and was fraction V enzyme. Strains of T7 bacteriophage containing amber mutations and *E. coli* strains B and O11′ were obtained from Dr F. W. Studier and were grown according to Studier[12]. T7 342-15, which contains a mutation in gene 1 rendering the growth of the phage temperature sensitive, was obtained from Dr W. C. Summers[4]. *E. coli* infected with T7 bacteriophage were grown in a "Biogen" (American Sterilizer Co.). *E. coli* B/1 were grown to a density of 3×10^9 cells per ml. with maximum aeration using M9 medium[12] supplemented with additional ammonium chloride and 5 g/l. of glucose. T7 bacteriophage were added to give a multiplicity of 3 and after 12·5 min the cells were rapidly chilled and harvested by continuous flow centrifugation. Infected cells were stored at −15° C until use.

RNA polymerase was purified from T7-infected cells by two methods. Procedure I was carried out essentially as described for isolation of *E. coli* RNA polymerase from uninfected cells[11] using T7-infected cells. RNA polymerase assays done during this procedure were done as described by Berg *et al.*[11] using T7 DNA as template. Procedure II was devised to obtain T7 specific RNA polymerase (Table 1). RNA polymerase assays for this enzyme

Table 1. SUMMARY OF PURIFICATION PROCEDURE II

Fraction	Volume (ml.)	Total activity (units $\times 10^{-3}$)	Protein (mg/ml.)	Specific activity (U/mg)	Percentage total activity
A. Extract	47	570	20	600	100
B. Streptomycin supernatant fluid	40	370	15	630	65
C. $(NH_4)_2SO_4$ extract fraction	9	202	14·5	1,500	35
D. DEAE-cellulose pooled fractions	90	200	0·25	8,800	35
E. Phosphocellulose pooled fractions	33	125	(0·03)	(120,000)	22
F. Concentrated phosphocellulose fractions	3·1	87	0·23	120,000	15

All operations were carried out at 0°–4° C and all centrifugations were carried out for 30 min at 15,000 r.p.m. in the 'SS 34' rotor of the Sorvall 'RC IIB' centrifuge except where specified otherwise. T7-infected cells (13 g) were mixed with 26 g of cold, acid-washed alumina powder and 0·4 ml. of 0·05 M Tris-HCl (*p*H 8)–0·01 M $MgCl_2$–0·0001 M dithiothreitol (DTT)–5 per cent glycerol (buffer A) and the mixture was ground in a mortar for 12 min. Buffer A (30 ml.) was added and the viscous mixture was mixed thoroughly and was centrifuged for 1 h. The supernatant fluid was diluted to a protein concentration of 20 mg/ml. (fraction A, 47 ml.). To fraction A was added 3·3 ml. of 10 per cent streptomycin sulphate and the mixture was stirred for 15 min and then centrifuged. The supernatant fluid (fraction B, 39 ml.) was decanted and 10·8 g of ammonium sulphate added. After 30 min of gently stirring the precipitate was collected by centrifugation and extracted in a 50 ml. centrifuge tube with 8 ml. of 1·2 M ammonium sulphate in 0·01 M Tris-HCl (*p*H 8)–0·0001 M dithiothreitol–DTT 5 per cent glycerol (buffer I), using a tightly fitting pestle. After 30 min the suspension was centrifuged. The supernatant fluid was saved and the pellet extracted again exactly as before to give a second supernatant fluid. The two supernatant fluid fractions were pooled (volume 16 ml.) and 2·06 g of ammonium sulphate added. After 30 min the precipitate was collected by centrifugation and dissolved in buffer I (fraction C, 9 ml.). Fraction C was dialysed for 3 h against two changes of 500 ml. each of buffer I in a rapid dialysis apparatus[13] and then diluted to 3 mg/ml. protein concentration. The enzyme was adsorbed to a column of DEAE-cellulose (20 cm length × 3 cm² cross section) equilibrated with buffer I. Elution was carried out with a linear gradient from 0·05–0·4 M KCl in buffer I (total volume 400 ml.). Fractions containing a high specific activity of T7 RNA polymerase were pooled (fraction D, 90 ml.) and immediately passed through a column of phosphocellulose (Whatman 'P-11'; 20 cm length × 3 cm²) previously equilibrated with buffer I containing 0·15 M KCl. A flow rate of about 1 ml./min is maintained. The enzyme is eluted from the column with a linear gradient from 0·15–1·0 M KCl in buffer I (total volume 300 ml.). Fractions containing a high specific activity of T7 RNA polymerase and showing only a single protein band on sodium dodecyl sulphate SDS-acrylamide gel electrophoresis were pooled (fraction E, 22 ml.) and concentrated by pervaporation[14] against buffer I to give a final protein concentration of more than 0·25 mg/ml. (fraction F, 3·1 ml.). These fractions were stored at 0° C or, after addition of an equal volume of glycerol, at −15° C.

were carried out as in procedure I with the following modifications. The enzyme was diluted in a solution containing 0·05 M Tris-HCl (*p*H 8), 0·01 M 2-mercaptoethanol and 2 mg/ml. of bovine serum albumin (BSA). Reaction mixtures contained 4 μmoles of Tris-HCl (*p*H 8), 2 μmoles of $MgCl_2$, 1 nmole of 2-mercaptoethanol, 100 μg of BSA, 36 nmole of T7 DNA, 40 nmole of ATP, CTP, GTP and UTP, and 0·5–10 units of enzyme in a final volume of 0·1 ml. One of the nucleoside triphosphates was labelled with α-^{32}P or ^{3}H at a specific activity of 2,000–20,000 c.p.m. per nmole. The rate of nucleotide incorporation with T7 RNA polymerase was constant for at least 20 min at 37° C with infected cell extracts or with the purified enzyme. Standard assays were terminated after 10 min incubation at 37° C and the amount of acid-insoluble radioactivity was determined as before. The amount of nucleotide incorporation was directly proportional to the amount of enzyme added to the reaction over the range of activity given above. One unit of activity is the amount of enzyme which gives a rate of 1 nmole of AMP incorporation in 1 h at 37° C in the standard assay. The activity of *E. coli* RNA polymerase holoenzyme is essentially the same in the two different assay procedures.

Two RNA Polymerase Activities

As a result of the studies of Summers and Siegel[4] it seemed likely that *E. coli* RNA polymerase in cells infected with T7 would be modified by replacement of the sigma subunit. To study the properties of such a modified polymerase we chose procedure I, which should allow isolation of the virtually intact enzyme. During the purification there were extensive losses in RNA polymerase activity. The missing activity did not appear in discarded fractions, so it was assumed that the activity was unstable, although the *E. coli* RNA polymerase is quite stable in similar conditions. Gradient elution of the enzymatic activity from DEAE-cellulose resolved two separate peaks of RNA polymerase activity, one in the range of 0·15 M KCl (fraction 5A), and the second in the range of 0·25 M KCl (fraction 5B). RNA polymerase in uninfected cells elutes at about 0·25 M KCl, in a position similar to fraction 5B. Fractions 5A and 5B contained 1·5 and 3 per cent, respectively, of the initial RNA polymerase activity measured in the original extract.

Characterization of these two fractions revealed that fraction 5A was highly active with T7 DNA as template, but did not use dAT copolymer whereas fraction 5B was active with both templates but most active with dAT copolymer (Table 2). The template specificity of fraction 5A was remarkable, for *E. coli* RNA polymerase is highly active with dAT copolymer as template whether or not it contains the sigma subunit (see Table 2). From the specific activities of the two fractions and the known specific activity of the *E. coli* RNA polymerase it was estimated that the fractions were probably about 30 per cent pure, that is, one-third of the protein in each fraction

Table 2. ACTIVITIES OF RNA POLYMERASE FRACTIONS FROM T7-INFECTED *E. coli*

Fraction	Source	Specific activity T7 DNA (U/mg)	Specific activity dAT copolymer (U/mg)	Ratio T7/dAT
5A	T7-infected *E. coli*	2,500	64	39
5B	T7-infected *E. coli*	1,700	4,000	0·4
RNA polymerase holoenzyme	*E. coli*	8,100	20,000	0·4
Core polymerase	*E. coli*	880	16.000	0·06

Data for *E. coli* polymerases are from Berg *et al.*[11]. Where indicated, 20 nmoles of dAT copolymer replaced T7 DNA as template.

would be RNA polymerase. Analysis of the two fractions by electrophoresis in SDS-acrylamide gels indicated that fraction 5B contained an appreciable amount of a protein component having the size of the subunits β' and β of the *E. coli* RNA polymerase[15,10]. Fraction 5A contained no detectable β bands, however, suggesting that the enzymatic activity was not associated with these subunits of the host RNA polymerase. We tested this possibility further by measuring the sensitivity of the two fractions to inhibitors of *E. coli* RNA polymerase: rifamycin[17], streptolydigin[18], and a purified γ-globulin fraction prepared from a high titre antiserum to *E. coli* RNA polymerase (Table 3). It is clear that fraction 5B behaves as would be expected if most of its RNA polymerase activity were *E. coli* polymerase*. By contrast, fraction 5A is insensitive to both drugs and its activity is not affected by antibody to *E. coli* RNA polymerase. This suggested that T7 bacteriophage might induce a new RNA polymerase protein in infected cells.

Table 3. INHIBITION OF T7 RNA POLYMERASE FRACTIONS BY RIFAMYCIN, STREPTOLYDIGIN AND ANTIBODY TO *E. coli* RNA POLYMERASE

Enzyme	Additions	Activity for T7 RNA synthesis (per cent)
E. coli B RNA polymerase	—	100
	Streptolydigin	4
	Rifamycin	< 1
	Antibody	10
T7 RNA polymerase, fraction 5A	—	100
	Streptolydigin	100
	Rifamycin	100
	Antibody	91
T7 RNA polymerase, fraction 5B	—	100
	Streptolydigin	22 (7)
	Rifamycin	18 (3)
	Antibody	40 (31)

Incorporation of ^{14}C-AMP into T7 RNA was followed as before with the addition of 2×10^{-4} M streptolydigin, 20 μg/ml. rifamycin or 0·02 A_{280} unit of purified antibody to *E. coli* RNA polymerase where noted. With *E. coli* RNA polymerase, T7 RNA polymerase fraction 5A, and 5B, 1·2, 1·1 and 1·5 nmoles of ^{14}C-AMP were incorporated, respectively, in the absence of inhibitors. Values given in parentheses for T7 RNA polymerase fraction 5B are those obtained with dAT copolymer as template.

Purification and Characterization of T7 RNA Polymerase

Preliminary characterization of the T7 RNA polymerase using fraction 5A led to the modification of the assay conditions. In particular, the activity—both in extracts and in purified fractions—is lost if the enzyme is diluted for assay in solutions without high concentrations of BSA. Considering other differences between the T7 RNA polymerase and the *E. coli* enzyme, we believe that this factor accounts for the extensive losses of enzyme activity incurred during purification by procedure I and also for the failure of previous workers to identify T7 RNA polymerase. Using the modified RNA polymerase assay it was found that RNA polymerase activity increases at least thirty-fold after infection by T7. This activity is stable in cell-free extracts for at least 1 week when the extracts are kept at 0° C. A purification for the T7 RNA polymerase was devised using the assay described and adding 20 μg/ml. of rifamycin to all assays. In these conditions the *E. coli* RNA polymerase is not active and one can fractionate selectively for the T7 RNA polymerase activity. Procedure II gives about a 130-fold purification of the initial T7 RNA polymerase activity with a reasonable recovery of total activity. Analysis

* The residual activity seen with fraction 5B in the presence of rifamycin or streptolydigin arises from trace contamination of this fraction by T7 RNA polymerase as shown by the lack of rifamycin resistant activity with dAT as template. The activity of fraction 5B with dAT was also more than 90 per cent sensitive to anti-*E. coli* RNA polymerase antibody when larger amounts of antibody were added.

of the enzyme fractions obtained after chromatography on phosphocellulose using SDS-acrylamide gel electrophoresis (Fig. 1) shows that tubes with the highest enzyme activity contain a single major protein component which has a molecular weight of about 107,000 (Fig. 1). When large amounts of protein from T7 polymerase fraction F are analysed, traces of other proteins are detected (Fig. 1). But fraction F T7 RNA polymerase consists of at least 80 per cent of this single protein component. Protein components which could be subunits of *E. coli* RNA polymerase are present in only trace amounts if at all. The final specific activity of T7 RNA polymerase is extremely high. Although protein determinations by the Lowry procedure are made difficult by the low concentrations of protein in fraction E and by the fact that buffer I interferes with the determination, it is clear that the specific activity of these fractions is about fifteen times higher than that of the *E. coli* RNA polymerase acting with T7 DNA template.

As found for fraction 5A, the purified T7 RNA polymerase is not inhibited by high concentrations of rifamycin (100 μg/ml.), streptolydigin (2×10^{-3} M), or of antibody to *E. coli* RNA polymerase. The enzyme requires Mg^{2+} as a divalent metal ion and is not active when Mn^{2+} replaces Mg^{2+}. T7 RNA polymerase shows optimal activity at 2×10^{-2} M Mg^{2+} as compared with 8×10^{-3} M Mg^{2+} for the *E. coli* enzyme[19]. T7 RNA polymerase is strongly inhibited by KCl at concentrations exceeding 0·05 M and is essentially inactive at 0·15 M KCl. The T7 enzyme shows a remarkable template specificity. Whereas *E. coli* RNA polymerase shows equivalent activities with T7 and T2 DNAs and is highly active with dAT copolymer, T7 RNA polymerase is active only with T7 DNA (Table 4). Denatured T7 DNA is active but much less so, and T2 DNA, λ DNA and dAT copolymer are almost inactive as templates. The homopolymer pair dG·dC is highly active for poly rG synthesis but does not direct poly rC synthesis at all with T7 RNA polymerase. This suggests that the T7 enzyme is highly specific in its recognition of initiation sites on DNA; although such sites occur on T7 DNA, they are lacking on any of the other DNAs we have tested and are not replaced by dAT copolymer. The activity of T7 RNA polymerase on dG·dC suggests that the promoter sites recognized by this enzyme may be C-rich regions of the DNA. Such regions are known to occur in T7 DNA[20].

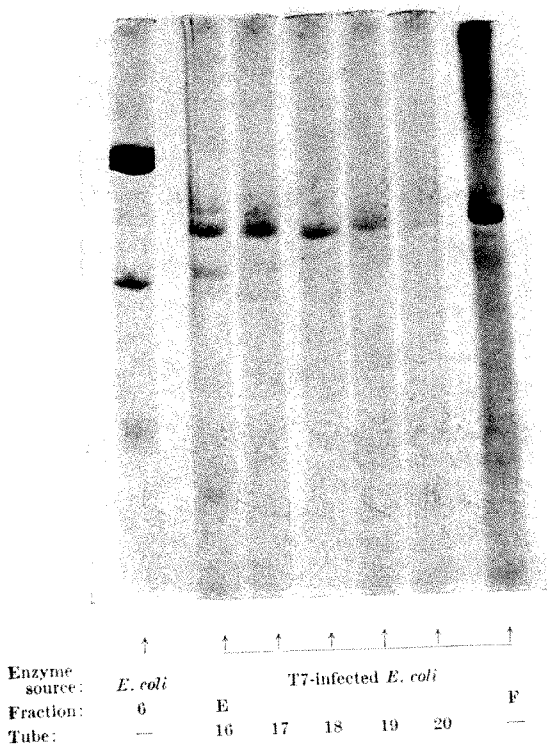

Fig. 1. Analysis of T7 RNA polymerase fractions in SDS-acrylamide gels. Samples contained 8 μg of *E. coli* RNA polymerase fraction 6, 1·5–3 μg of T7 RNA polymerase fractions from phosphocellulose chromatography (fractions E 16–20) or 11 μg of T7 RNA polymerase fraction F. The protein was analysed by gel electrophoresis in SDS-acrylamide gels and was stained with coomassie blue. The peak of T7 RNA polymerase activity eluting from phosphocellulose was found in fractions 17–19 which contained enzyme with a constant specific activity of 120,000 U/mg. Protein in these fractions was concentrated for gel analysis by precipitation with 10 per cent trichloroacetic acid.

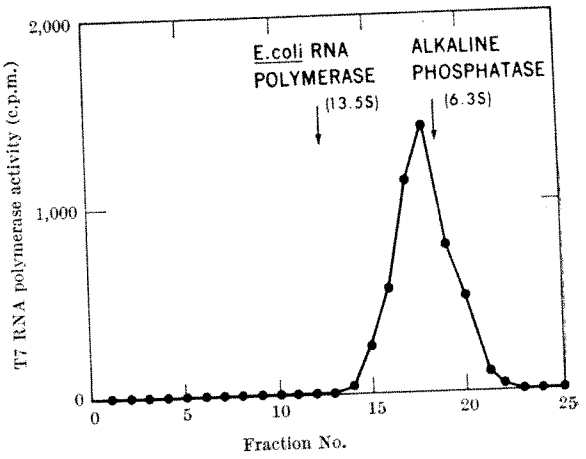

Fig. 2. Zone sedimentation of T7 RNA polymerase in a glycerol gradient. T7 RNA polymerase (33 U), fraction 5A, was layered on a 10–30 per cent glycerol gradient and sedimented at 40,000 r.p.m. for 11·5 h. All solutions contained 1 mg/ml. BSA, 0·2 M KCl and buffer I. Fractions were collected and were analysed for T7 RNA polymerase activity. Sedimentation standards, *E. coli* RNA polymerase fraction 5 and *E. coli* alkaline phosphatase, were run in a duplicate tube during the same run. The arrows indicate the peak position of each.

Table 4. COMPARISON OF ACTIVITIES OF *E. coli* RNA POLYMERASE AND T7 RNA POLYMERASE WITH DIFFERENT DNA TEMPLATES

Template	Specific activity (U/mg) *E. coli* polymerase	T7 polymerase
dAT copolymer	15,000	140
dG·dC	17,000 (^{3}H-GTP)	40,000 (^{3}H-GTP)
	8,700 (^{3}H-CTP)	< 90 (^{3}H-CTP)
T7 DNA	7,700	68,000
Denatured T7 DNA	950	24,000
T2 DNA	6,000	< 60
λ DNA	1,700	300

Where indicated, 40 nmoles of the indicated DNA or 20 nmoles of dAT or dG·dC replaced T7 DNA in the standard assay for T7 RNA polymerase. When dG·dC was used as template, only ^{3}H-CTP and GTP or ^{3}H-GTP and CTP were added as nucleotide substrates. Assays were carried out using 0·15 μg of fraction F T7 RNA polymerase or 0·14 μg of fraction 5 *E. coli* RNA polymerase.

To test the specificity of the T7 RNA polymerase further we determined the strand specificity of the T7 RNA formed by T7 RNA polymerase with native T7 DNA as template. *In vivo*, all T7 RNA seems to be transcribed from the r-strand of T7 DNA[21], so that synthesis of l-strand specific RNA would signal that non-specific transcription was occurring. More than 95 per cent of the T7 RNA formed by T7 RNA polymerase is r-strand specific, indicating that T7 RNA polymerase does initiate RNA chains at specific sites on the T7 template (Table 5).

Analysis of T7 RNA polymerase by sedimentation through a glycerol gradient showed a single peak of enzymatic activity (Fig. 2). Calibration of the gradient[22], using *E. coli* RNA polymerase ($s_{20,w} = 13·5S$[10]) and *E. coli* alkaline phosphatase ($s_{20,w} = 6·3S$[23]) as sedimentation standards, gave an estimate of $s_{20,w} = 7·2S$ for the

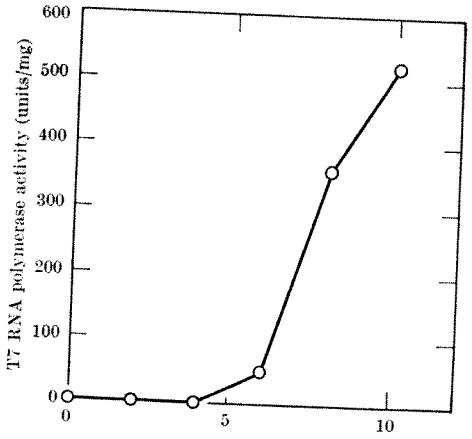

Fig. 3. Induction of T7 RNA polymerase activity after T7 bacteriophage infection. *E. coli* B/1 were grown at 37° C in 1·5 l. of M9 medium containing 5 g/l. of glucose. When cell density reached 1×10^8 cells/ml. the cells were chilled and harvested and were suspended in 28 ml. of M9 medium. An aliquot (2·5 ml.) was taken as an uninfected sample and $7{\cdot}5 \times 10^{13}$ purified T7 phage were added in 0·3 ml. After 10 min at 0° C the cells were diluted into 475 ml. of prewarmed M9 medium which contained 5 g/l. glucose and the culture was shaken vigorously at 30° C. Aliquots (100 ml.) were taken at 2 min intervals and were chilled rapidly by pouring the solution on ice at −15° C. The cells were collected by centrifugation, were suspended in 1 ml. of buffer A, and were disrupted by sonic vibration for 2·5 min at 50 V using a Bronwill sonic vibrator. The extracts were centrifuged and the supernatant fluid was assayed for protein and for T7 RNA polymerase activity. Assay reactions contained 20 μg/ml. of rifamycin and 4×10^{-4} M streptolydigin and used ^{3}H-CTP as the labelled nucleotide. In these conditions *E. coli* RNA polymerase is not active. Uninfected *E. coli* extracts contain about 25 units/mg of RNA polymerase activity with T7 DNA as template, when assayed in similar conditions in the absence of rifamycin.

T7 RNA polymerase. If one assumes that the protein is globular and that $\bar{v} = 0{\cdot}73$, this would correspond to a molecular weight of about 100,000 (ref. 24). This result, taken with the results of SDS-gel analysis, suggests that the native T7 RNA polymerase consists of a single polypeptide chain of molecular weight 100,000–110,000.

Table 5. STRAND SPECIFICITY OF T7 RNA SYNTHESIZED USING T7 RNA POLYMERASE

Enzyme	RNA annealing to T7 DNA (c.p.m.)		Percentage r-strand RNA
	r-strand	l-strand	
E. coli RNA polymerase	1,159	282	80
T7 RNA polymerase	1,045	63	94

T7 RNA was synthesized in a standard T7 RNA polymerase assay scaled up to 1·0 ml. using either 18 μg of fraction 6 *E. coli* RNA polymerase (2 min reaction, 28 nmoles RNA formed) or 4 μg of fraction F T7 RNA polymerase (10 min reaction, 70 nmoles RNA formed). ATP was labelled with ^{32}P at a specific activity of 100,000 c.p.m./nmole. The reaction was terminated with 10 μg of pancreatic deoxyribonuclease, and after 10 min at 37° C the RNA was extracted three times with phenol. Aliquots of the aqueous phase were assayed for acid-insoluble radioactivity and for their ability to anneal to the separated strands of T7 DNA[21] using a modification of the method of Gillespie and Spiegelman[27]. The total amount of RNA annealing to r and l strands was about 30 per cent of that added to the annealing mixture. Similar efficiencies were obtained when annealing either RNA product to T7 DNA which had not been separated into r and l strands.

T7 RNA polymerase did not interact physically with *E. coli* RNA polymerase holoenzyme or core polymerase when the two purified enzymes were mixed and were sedimented together in a glycerol gradient. Furthermore, T7 polymerase did not stimulate the synthetic activity of *E. coli* core RNA polymerase on T7 DNA when the two were mixed in an assay. *E. coli* polymerase holoenzyme did not stimulate synthesis by T7 RNA polymerase with T7 DNA as template. Thus T7 RNA polymerase seems to be a complete polymerase *per se* and neither replaces the *E. coli* RNA polymerase sigma component nor binds to the *E. coli* core polymerase in its stead.

Appearance of T7 RNA Polymerase in Infected Cells

Studier and Maizel[25] have shown that there are two principal classes of T7 induced proteins; early proteins which begin to appear 5–7·5 min after infection at 30° C, and late proteins after about 10 min. To determine to which of these classes the T7 RNA polymerase belongs, *E. coli* B/1 cells were grown in minimal medium with glucose and were infected at 0° C to allow synchronous infection[21]. The infected cells were then diluted into prewarmed medium and samples were taken at intervals to follow the appearance of T7 RNA polymerase activity in extracts. The results (Fig. 3) show that T7 RNA polymerase activity appears 4–6 min after infection. Thus T7 RNA polymerase is an early T7 protein.

Structural Gene for T7 RNA Polymerase

Because only three early genes are currently known for T7 phage[25], it was of interest to determine if any of these might represent the structural gene for T7 RNA polymerase. The size of the T7 polymerase and its ability specifically to transcribe T7 DNA suggested that T7 gene 1 was a likely candidate, because it specifies a protein of about 100,000 molecular weight, the protein is required for the synthesis of late mRNA in T7-infected cells[25,26], and gene 1 mutants are defective in all known late T7 functions. In fact, no other protein of this size is synthesized in T7-infected cells[25]. Because of the availability of a variety of mutant T7 phages[12,4], this possibility was easily tested. Table 6 records the activity of T7 RNA polymerase in extracts of *E. coli* B/1 infected with amber mutants for T7 genes, 1, 2 and 3, and with a T7 mutant which contains a temperature-sensitive mutation in gene 1. Whereas extracts of cells infected with amber mutants for genes 2 and 3 have about half of the normal specific activity of T7 RNA polymerase, the extract from cells infected with an amber mutation in gene 1 has no detectable T7 RNA polymerase activity. When extracts are prepared from cells infected with T7 tsl (342–15) the resulting extract (tsl extract) contains detectable but reduced levels of T7 RNA polymerase. By contrast with the T7 RNA polymerase activity obtained with extracts prepared from cells infected with wild-type T7 (T7+ extract), the activity in a tsl extract was unstable and 50 per cent of the activity was lost after overnight storage. Preliminary experiments showed that the rate of inactivation of T7 RNA polymerase activity in a tsl extract at either 37° C or 45° C was similar to the rate of inactivation found for RNA polymerase from a T7+ extract. The enzymatic activity of T7 RNA polymerase in a tsl extract was, however, strikingly reduced when assays were carried out at 45° C (Table 6). By contrast, the activity of T7 RNA polymerase in a T7+ extract was slightly enhanced when assayed at 45° C relative to 37° C. Thus a temperature-sensitive mutation in gene 1 affects the T7 RNA polymerase protein and seems to lead to reduced enzymatic activity at elevated temperatures, but not to an increased sensitivity to thermal denaturation. These results, taken with the lower initial activity of the enzyme in cells infected with T7 tsl and with the physical and biochemical properties of the T7 RNA polymerase, indicate that the structural gene for T7 RNA polymerase is gene 1.

Table 6. ACTIVITY OF T7 POLYMERASE IN EXTRACTS OF CELLS INFECTED WITH MUTANT T7 PHAGES

Phage	Genotype	T7 polymerase activity (U/mg)	
		37° C	45° C
T7+	Wild type	520	570
T7 tsl (342–15)	Temperature-sensitive, gene 1	48	18
T7 am 23	Gene 1 amber	< 2	—
T7 am 64	Gene 2 amber	290	—
T7 am 29	Gene 3 amber	260	—

100 ml. aliquots of *E. coli* B/1 (a nonpermissive strain for T7 amber mutants) were grown at 30° C in M9 medium containing 5 g/l. glucose to a density of 1×10^8 cells/l. A lysate of T7 phage was added to give a final multiplicity of five and growth was continued for 15 min. Infected cells were harvested, and extracts were prepared and assayed as described in Fig. 3.

Model for Regulation

The identification of T7 gene 1 protein as a new RNA polymerase provides a clear model for the positive control of transcription by T7 phage: the infecting T7 DNA is transcribed initially by the host RNA polymerase giving rise to early T7 mRNA. Translation of this early mRNA leads to T7 RNA polymerase along with two other early proteins of unknown function[25]. The T7 RNA polymerase then carries out the transcription of late T7 mRNA. The question remains how negative control of early T7 genes might occur. Synthesis of gene 1 protein seems to cease about 10 min after infection[25], at a time when late particle proteins are just beginning to appear. Thus T7 may have a mechanism to turn off transcription of early genes. Such a negative control of early transcription could result from modification leading to inactivation of the *E. coli* RNA polymerase by a late phage function, for the host enzyme is no longer needed after synthesis of the T7 RNA polymerase*. Extensive modification of *E. coli* RNA polymerase occurs after infection by T4 phage[28], and may serve a negative control function in the growth of that phage as well.

What implications does the identification of a T7-specific RNA polymerase have for our understanding of the control of transcription in other bacteriophage systems? At least three possible mechanisms have been proposed by which a bacteriophage could initiate transcription of a set of genes which it had not previously transcribed: (1) alteration of the initiation specificity of the host RNA polymerase by modification of the polymerase protein or by the synthesis of a new subunit such as sigma subunit[3]; (2) *de novo* synthesis of a new RNA polymerase having an altered initiation specificity, and (3) synthesis of a protein factor (anti-termination factor) which prevents normal termination of RNA chains and so allows the host RNA polymerase to "read through" to distal genes[29,30]. These mechanisms are not mutually exclusive; in the case of complex bacteriophages such as λ phage and T4 phage, at least three classes of transcriptional units are known, and more than one positive control mechanism may well be used.

Alteration of transcriptional specificity of RNA polymerase by replacement of sigma subunit with a subunit carrying a new initiation specificity has been proposed to occur during growth of T4 and λ phages and during sporulation of *B. subtilis*[31]. Although there is good evidence for modification of bacterial RNA polymerases in some of these systems, there is still no evidence that this modification confers a new transcriptional specificity on the RNA polymerase *in vivo*. In particular, as discussed, negative control mechanisms through which certain genes are turned off are present in all of these systems. It is possible that most modifications of bacterial RNA polymerase are directed to such an end and not toward activation of the enzyme for a new function.

In the case of bacteriophages λ and T4, it seems likely that synthesis of early and delayed early classes of mRNA is mediated directly by the host cell RNA polymerase by a mechanism such as the first or third and not by phage-directed synthesis of a new RNA polymerase. Activation of late transcriptional units in λ and T4 infected cells is, however, more complex. At least one new phage protein is directly required for late transcription in each case, T4 gene 55 (ref. 32) and λ gene Q[33]. Evidence that the host RNA polymerase itself is responsible for late transcription in T4 and λ-infected cells is based primarily on studies which show that phage growth and also mRNA synthesis remain sensitive to rifamycin throughout phage infection[34,35]. By contrast with these results, the growth of T7 phage becomes resistant to rifamycin inhibition after 5 min, the time at which the T7 RNA polymerase appears[4]. One interpretation of the continued sensitivity of late transcription to rifamycin in λ and T4-infected cells is that the host cell RNA polymerase is directly involved in late transcription as proposed by mechanism 1 or 3. Alternatively, our results suggest that late transcription might be carried out by a new phase-specific polymerase as in mechanism 2. Such a late RNA polymerase could be specified by gene 55 and T4 and by gene Q in λ phage. By this hypothesis, the sensitivity of late transcription to rifamycin would be the result of a continued requirement for host cell RNA polymerase for some other phage function. This would result, for example, if a small amount of early or delayed early transcription were continually required for late transcription to continue. In the case of phage λ, some evidence supports this latter possibility, for both N gene function and an active, early r-strand promoter site seem to be continually required for late transcription[36,37], and the N gene product seems to be unstable during growth[38,39]. Thus it is possible that the initiation of transcription of late phage genes by *de novo* synthesis of a bacteriophage specific RNA polymerase may prove to be a general mechanism for the activation of late bacteriophage transcription.

This investigation was supported by a US Public Health Service research grant and training grant from the Institute of General Medical Sciences. We would like to thank Drs Paul Berg, Richard Calendar and Harrison Echols for criticism and discussion.

* T7 RNA polymerase fraction 5B from procedure I seems to be composed of host cell enzyme subunits and is active as an RNA polymerase on both T7 DNA and T2 DNA templates. This does not rule out the possibility that the *E. coli* RNA polymerase is modified or inactivated in T7-infected cells, however, because we cannot yet exclude the possibility that the active polymerase in this fraction is derived entirely from uninfected cells present, in the infected cell population.

Evidence for Premature Termination of Transcription of the Tryptophan Operon in Polarity Mutants of *Escherichia coli*

by
FUMIO IMAMOTO*
Department of Microbial Genetics,
Research Institute for Microbial Diseases,
Osaka University, Yamada-kami,
Suita, Osaka

The polarity of mutations in the tryptophan operon of *E. coli* may be caused not by an accelerated degradation of untranslated messenger operator-distal to the nonsense codon but by premature termination of transcription at or near the site of mutation and by restriction of RNA polymerase movement beyond it.

A NONSENSE mutation in a gene of a bacterial operon may both inactivate its protein product and decrease the level of synthesis of proteins coded by genes operator-distal to the mutation site. This polarity is associated with a decrease in the amount of mRNA for the operator-distal genes; although some of the mRNA synthesized by the operon corresponds to its whole length, much of it is shorter and corresponds to genes operator-proximal to the mutant site[1,2]. The loss of mRNA from beyond the mutation site could result either from premature termination of transcription at or near the mutation[1,3-6] or from an accelerated degradation of the messenger corresponding to the operator-distal genes[1,6-9].

Previous reports have suggested that strong polar mutations in the first two genes (*E* and *D*) of the tryptophan operon of *Escherichia coli* suffer an accelerated degradation of untranslated messenger distal to the nonsense codon[7,9]. I suggest here, however, that polarity in this operon is caused rather by a premature termination of transcription. First, both strong polar and deletion mutants in the initial region of the first gene of the operon produce labile mRNA which can be detected only by a brief pulse label; this mRNA corresponds only to the region that is operator-proximal to a mutation site. I attribute this to premature termination of transcription near the mutation site. Second, the intragenic initiation of transcription caused by treating bacteria with dinitrophenol[10,11] is less frequent with strong polar than with weak polar mutants. Thus the strong polar mutants must possess a mechanism which limits transcription distal to the mutated site on the operon.

Production of Labile mRNA

I have characterized the labile mRNA synthesized at a steady state of transcription of the *trp* operon in strong polar mutants. It has been reported previously that strong polar mutants such as E9802[7], D9778[7] and D9838[9] produce labile mRNA which is only detectable in a very short period of labelling with ^{3}H-uridine. This possibility was investigated further in this experiment and the results obtained are represented in Fig. 1. A map of the *trp* operon, the nonsense mutations, the deletion mutations and φ80 pt phages used for assay of *trp* mRNA by DNA-RNA hybridization technique[11] is shown in Fig. 2. Pulse-labelling was started at the twentieth minute after derepression to assure a steady state of transcription of the operon. Bacteria were derepressed by transfer from rich medium to minimal medium containing 1·0 per cent glucose and a mixture of nineteen amino-acids at 0·5 mM each, lacking L-tryptophan. They were incubated at 30° C with vigorous shaking[11]. In these conditions, it takes about 6 min to complete a round of transcription of the operon[12].

As shown in Fig. 1, the most pronounced effect of varying the period of pulse labelling on the detectable level of *trp* mRNA is seen with the E mRNA of mutant E9802. The concentration of E mRNA rises as the duration of pulse labelling is decreased, while the levels of E_{distal} mRNA, D mRNA, and C–A mRNA do not. With D9778 and C9941, similar changes in the levels of *trp* mRNA are not observed. The labile mRNA in E9802 does not hybridize with DNA from φ80 pt E_{distal} phage (the *trp* gene segment of which corresponds to the operator-distal 1/3 portion of the E gene[13]) (see also Fig. 2).

Of ten polar mutants of the E gene examined for change of *trp* mRNA levels as a function of length of pulse labelling, six strong polar mutants (E9829, E9851, E10203, E9802, E12242 and E9758) produced detectable amounts of labile E mRNA, while the other mutants did not. Evidently, production of labile mRNA is characteristic of strains with nonsense alterations at the beginning of the operator-proximal gene. Some of these data are presented in Table 1. Short *trp* mRNA of E12242, E9758 and E9903 corresponds to the operator-proximal 45, 53 and 63 per cent of the intact E gene[13]. I have assumed that the molecular size of the short messenger of the polar mutants corresponds to the distance from the beginning of the operon to the site of the mutational alteration[2]. The distance from the mutational site in E12242 or E9758 to the site in E9903 should therefore correspond to only 18 or 10 per cent, respectively, of the E gene. As shown in Table 1, twice as much E12242 and E9758 E mRNA is detectable with very short pulse labellings compared with labelling for 2 min. These labile messengers are not hybridizable with DNA from φ80 pt E_{distal} phage. Thus the bulk of labile mRNA produced by strong polar mutants such as E12242 and E9758 must correspond to the operator-proximal region before the nonsense mutation in the E gene. The other strong polar mutants such as E9851, E9829 and E10203 also produce labile E mRNA which corresponds to the region proximal to the site of the mutational alteration of E9903.

Consistent with this, I have also observed that deletion of the operator-distal half of the E gene does

Table 1. CHANGES IN *trp* mRNA LEVEL IN POLAR MUTANTS AS A FUNCTION OF PERIOD OF PULSE LABELLING

RNA source		Amount of *trp* mRNA synthesized		
Strain	Period of pulse labelling (s)	E mRNA ($\times 10^{-3}$ per cent)	E_{distal} mRNA	Labile E mRNA* ($\times 10^{-3}$ per cent)
E12242	10	413	13	201
	20	404	12	192
	120	212	15

	20	435	60	49
	120	386	62	
E9887	10	448	56	96
	20	434	51	82
	120	352	51	

Tritiated RNA was prepared from bacterial cultures pulse labelled with 200 μCi of ^{3}H-uridine (15 Ci/mmole) for various periods at the tenth minute after derepression. In standard conditions[12], 47–64 μg of E12242 ^{3}H-RNA (specific activity, 2,200–21,900 c.p.m./μg), 49–73 μg of E9758 ^{3}H-RNA (specific activity, 1,700–17,500 c.p.m./μg), 61–76 μg of E9903 ^{3}H-RNA (specific activity, 2,900–19,500 c.p.m./μg) or 58–68 μg of E9887 ^{3}H-RNA (specific activity, 2,100–18,200 c.p.m./μg) were used for each hybridization assay. The other conditions were as described in Fig. 1.

* The *trp* mRNA values of RNA from cultures pulse-labelled for 2 min were subtracted in each case.

* Present address: Department of Biology, University of Virginia, Charlottesville, Virginia 22903.

not affect the production of labile messenger by mutant E9829; a double mutant, KAE-44–E9829, which retains the nonsense mutation E9829 operator–proximal to a deletion terminus KAE44 in the E gene (see Fig. 2) produces almost the same amount of labile messenger as E9829. The extent of polarity, in the sense of production of short *trp* mRNA, has been observed to remain as strong in KAE44–E9829 as in the parent strain, E9829 (F. I. and Y. Kano, to be published elsewhere).

The molecular size of *trp* mRNA synthesized during a very short labelling period such as 10 or 20 s was examined with E9802. If the *trp* mRNA synthesized consists of larger molecules than the mRNA detected during a 2 min labelling period because of selective degradation of the messenger segment distal to the nonsense mutation site, the sedimentation profile of these *trp* mRNA preparations should differ. On the contrary, as can be seen in Fig. 3, the sedimentation profiles of the *trp* mRNA isolated following the 10, 20 and 60 s labelling periods were essentially the same. It was not possible therefore to detect the production of larger *trp* mRNA molecules, as the pulse time was decreased.

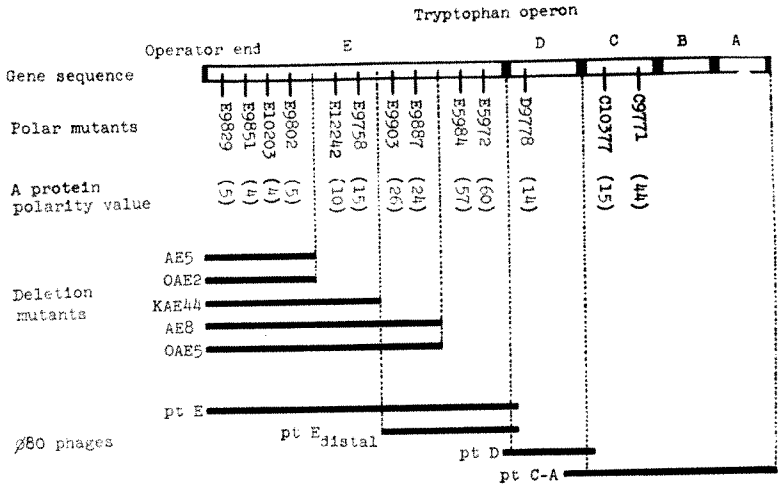

Fig. 2. Genetic map of the *trp* operon and relative polarity values in mutants. The order of mutationally altered sites and the A protein polarity values (in parentheses) were based on previous studies[2,15] and personal communication from C. Yanofsky. A protein polarity value is the percentage of A protein production by the mutant and by the wild type control. *Trp* operon segments carried by the deletion mutant or the φ80 pt are indicated by a solid line. The position of the deletion terminus is based on previous studies[12,19–21]. The relative size of the *trp* genes and distances between the mutant sites are only approximate. Phages were kindly supplied by Drs A. Matsushiro (φ80 and pt E$_{distal}$), S. Deeb and B. Hall (pt C–A), J. P. Gratia (pt E), C. Yanofsky (pt D) and M. Taylor (pt A). Deletion mutants, AE strains, and polar mutants were kindly supplied by Dr C. Yanofsky and deletion mutants, OAE strains, were kindly donated by Dr J. Ito. Deletion mutant, KAE[44], was isolated by Dr Y. Kano.

If transcription of the *trp* operon in strong polar mutants is frequently terminated near the site of the nonsense alteration, the messenger detached prematurely from the operon might be rapidly attacked by nuclease and degraded. When a constant period of pulse labelling is used, the probability of survival of premature messenger might decrease with shortening of the length of the transcribable region. This possibility has been demonstrated in experiments measuring detectable *trp* mRNA as a function of the length of pulse labelling with various deletion mutations of the E gene[13]. The *trp* mRNA produced by the deletion mutant such as AE5, OAE2, AE8 or OAE5 has been determined to correspond to the operator–proximal 33, 40, 63 or 63 per cent, respectively, of the intact E gene[13]. Comparison of the order of the molecular size of the *trp* mRNA from various polar and deletion mutants with the order of the mutational alterations and deletion termini on the genetic map has indicated that *trp* mRNA size increases in relation to the distance from the beginning of the operon to the site of the deletion termini, which indicates that the *trp* mRNA molecules of these deletion mutants have apparently terminated near the site of their deletion termini[13]. Because the nonsense alteration sites of six strong polar E gene mutants that produce labile messenger are located within the operator–proximal 53 per cent of the E gene (to the site of E9758), two deletion mutants, AE5 and OAE2, might also be expected to produce labile messenger. These expectations have been realized: the deletion mutants AE5 and OAE2 exhibit twice or three times as much E mRNA in very brief pulse labelling as in 2 min labelling, and the E mRNA level falls as the length of exposure to ^{3}H-uridine is increased.

The analogous production of labile mRNA in the strong polar and deletion mutants of the E gene suggests that a segment of the *trp* messenger, detached prematurely from the operon in the strong polar mutants as a result of termination of transcription at or near the site of nonsense alteration, is exposed to a critical condition of nucleolytic attack. It is of interest that the stability of messengers detached from the DNA template has been shown in *E. coli* to be lower than those attached to the template[14].

In these experiments, rapid degradation of messenger corresponding to the region proximal to the nonsense alteration occurred only in strong polar mutants with nonsense alterations in the initial region of the E gene. In a previous article[7], Morse and Yanofsky reported accelerated degradation of messenger distal to the nonsense codon of the mutated gene. One E and two D gene polar mutations have been reported to have that effect[7,9].

These contradictory findings can probably be attributed to differences in the two groups of experiments. Morse and Yanofsky used 3-indolyl propionic acid to derepress the *trp* operon in bacteria growing in minimal medium. I have effected derepression by transferring bacteria grown in rich medium to minimal medium lacking trypto-

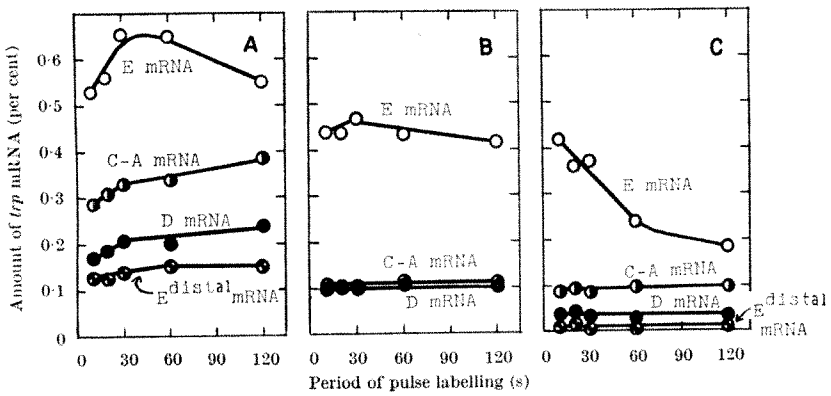

Fig. 1. Changes in *trp* mRNA level as a function of the duration of pulse labelling. Tritiated RNA was prepared from cultures of C9941, a CRM mutant of the C gene (*A*), D9778 (*B*) or E9802 (*C*) pulse labelled with 200 μCi of ^{3}H-uridine (15 Ci/mmole) for various periods indicated at the twentieth minute after derepression. Conditions for derepression are described in the text. In standard conditions[12], 59–65 μg of C9941 ^{3}H-RNA (specific activity, 1,900–12,500 c.p.m./μg), 61–69 μg of D9778 ^{3}H-RNA (specific activity, 2,500–20,500 c.p.m./μg) or 72–93 μg of E9802 ^{3}H-RNA (specific activity, 1,700–11,200 c.p.m./μg) annealed with 5 μg of heat-denatured phage DNA in a 0·25 ml. reaction mixture. The values of *trp* mRNA are represented as percentage of total labelled RNA and are the averages of duplicate determinations. The *trp* mRNA hybridizable specifically with DNA from pt E, pt E$_{distal}$, pt D or pt C–A phages is represented as E mRNA, E$_{distal}$ mRNA, D mRNA or C–A mRNA, respectively. The other conditions of determination and calculation of *trp* mRNA are as reported previously[11,12].

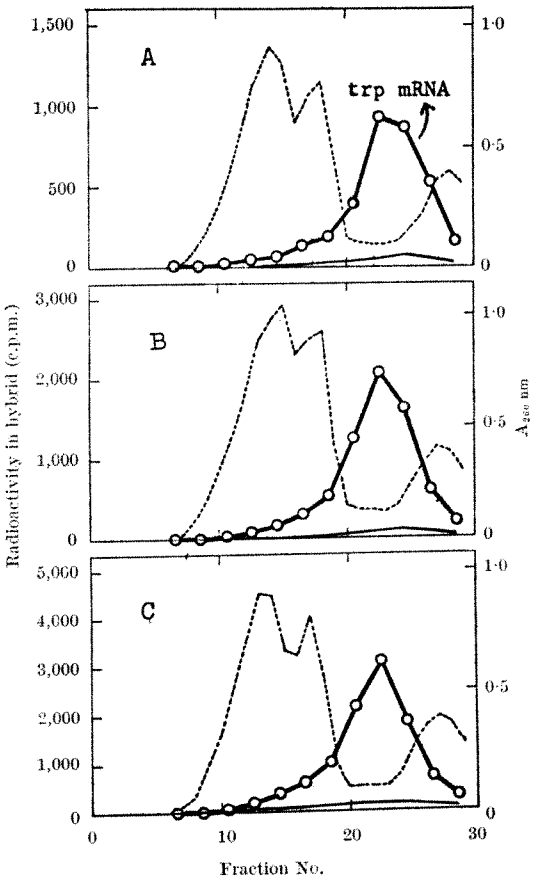

Fig. 3. Comparison of sedimentation profiles of *trp* mRNA from E9802 pulse labelled for various periods at steady state transcription. Pulse labelling was carried out with 500 μCi of ^{3}H-uridine (15 Ci/mmole) for 10 (*A*), 20 (*B*) and 60 (*C*) 20 min after derepression. Tritiated RNA was sedimentated in a 5–30 per cent linear sucrose gradient, containing 0·01 M Tris-HCl (*p*H 7·3) and 0·05 M KCl, for 5 h at 36,000 r.p.m. A three-eighths portion of each fraction was assayed with DNA from pt E phage to determine *trp* mRNA. The other conditions are as described previously[11]. - - - -, Absorbance at 260 nm; ———, hybridization with φ80 DNA (background value); ○—○, difference between hybridization with pt E DNA and φ80 DNA (E mRNA).

phan. In the former conditions, D gene polar mutants have been observed to show rapid degradation of D gene messenger. This effect has never been seen with R^-_{trp} (repressor-deficient) strains carrying D gene polar mutations (personal communication from D. E. Morse), although polarity of this operon has been known to be invariant to the R_{trp} mutation[2,15]. In fact, in the conditions of the present experiments, E9829 and E9758 have been observed to produce labile messenger in the parental R^+_{trp} strains (F. I. and Y. Kano, to be published elsewhere). The disagreement between results might be resolved when further information is obtained about how different techniques of derepressing the *trp* operon affect the degree of polarity.

Differences in *trp* mRNA assay systems might also be responsible for discrepancy in the findings with E9802. Morse and Yanofsky defined $E_{proximal}$ mRNA in terms of the difference between hybridization with DNAs from φ80 pt ED_{25} containing all of the D and E genes, and φ80 pt D_2 containing all of the D and a distal part of the E gene. The *trp* segment of φ80 pt D_2 is known to cover the E gene region distal to the E9851 site (personal communication from C. Yanofsky; refs. 7 and 21). The difference of annealing of RNA to these two DNAs is a small fraction of the annealing with either DNA alone. There are also problems associated with the efficiency of hybridization. Thus these experiments must be regarded as testing the limits of current technical capabilities.

Lower Frequency of Intragenic Initiation

I have investigated the distribution of RNA polymerase molecules over the region of the *trp* region distal to the mutated gene. If bacteria are incubated in derepression conditions with 2,4-dinitrophenol (DNP), which severely but reversibly inhibits transcription of the derepressed operon, the newly synthesized *trp* messengers made after removal of the inhibitor are small in size and contain operator distal information. Transcription of the operon apparently is therefore initiated at sites within the operon[10,11]. These *trp* mRNA molecules are translated with almost normal efficiency[10]. If polarity results from rapid degradation of the segment of the messenger distal to the nonsense alteration which is caused by non-translation of this region of the polycistronic messenger, then after intragenic initiation of transcription in the presence of tryptophan (added to block ordinary initiation at the *trp* promotor), functional messenger could be synthesized from the region distal to the nonsense alteration. On the other hand, if polarity is attributed to premature termination of transcription leading to scanty distribution of polymerase molecules over the distal genes of the operon, then it might be expected that the frequency of intragenic initiation of transcription distal to the nonsense alteration would be diminished assuming that termination involves the dissociation of polymerase from its template.

These predictions were tested in the following experiment: DNP (5×10^{-3} M) was added to a derepressed culture 10 min after derepression (to ensure a steady state distribution of polymerases over the operon) and the culture was further incubated for 45 min at 30° C. During this incubation, *trp* mRNA molecules which had been synthesized before the addition of DNP were detached from the operon and broken down[13]. After the removal of DNP, bacteria were quickly transferred into the pre-warmed standard medium including L-tryptophan[11] and pulse labelled with ^{3}H-uridine for the first minute of incubation. Sedimentation profiles of *trp* mRNA molecules using a CRM mutant (A9952), two strong polar mutants (D9778 and C10377) and a weak polar mutant (C9771) labelled in repression conditions for 1 min immediately after the removal of DNP show that intragenic initiation of transcription has occurred with all these mutants in these conditions[13].

Production of *trp* messenger fragments lacking the operator-proximal segment of the operon, synthesized as a result of intragenic initiation, was determined with five strong polar mutants (E9802, E9829, E9758, D9778 and C10377), two weak polar mutants (E5984 and C9771) and a CRM mutant (C9941). Results (Table 2) show that frequency of intragenic initiations on the operator–distal (C, B and A) genes correlates closely with the extent of polarity: there is the expected reduced amount of messenger distal to the nonsense alteration. Similar experiments

Table 2. COMPARISON OF *trp* mRNA LEVELS OF VARIOUS POLAR MUTANTS IN THE STEADY STATE AND AT THE INITIAL STAGE AFTER INTRAGENIC INITIATION OF TRANSCRIPTION

Strain	Amount of C–A mRNA synthesized	
	In steady state	After intragenic initiation
	($\times 10^{-3}$ per cent)	
E9802	79	68
E9829	77	64
E9758	67	62
E5984	182	210
D9778	77	95
C10377	178	117
C9771	277	210
C9941	332	248

Tritiated RNA was prepared from bacterial cultures pulse labelled with 200 μCi of ^{3}H-uridine (15 Ci/mmole) for 1 min at the twentieth minute after derepression (steady state), or from cultures pulse labelled with 300 μCi of ^{3}H-uridine in conditions of repression during the first minute after the removal of DNP (intragenic initiation)[11]. In intragenic initiation, before the removal of the inhibitor, bacterial cultures were incubated in the presence of DNP (5×10^{-3} M), added at the tenth minute after derepression, for 45 min. In standard conditions[11], 41–60 μg of ^{4}H-RNA (specific activity, 5,800–11,500 c.p.m./μg) (steady state) or 24–38 μg of ^{3}H-RNA (specific activity, 3,300–10,600 c.p.m./μg) (intragenic initiation) was used for one hybridization assay. The other conditions were as described in Fig. 1.

in which only A mRNA was measured (with φ80 pt A DNA) yielded a similar result[13]. Transcription of the operator-distal genes of the *trp* operon is therefore limited in strong polar mutants. It is conceivable that molecules of RNA polymerase wander along the operon without transcribing in the presence of DNP and, upon removal of the inhibitor, resume synthesis of mRNA at any position in the operon. The reduced frequency of intragenic initiation observed with strong polar mutants may be attributed to a reduced number of RNA polymerase molecules on the operator–distal genes of the operon. This possibility is being examined.

Cessation of Transcription

The mechanism proposed to explain premature termination of transcription in the polar mutant demands coupling of transcription and translation[16]. RNA polymerase action is closely tied to ribosome movement, which is halted by a nonsense codon. Transcription is frequently terminated, therefore, when an altered nucleotide sequence in DNA is transcribed as a nonsense codon, making a subsequent region of the messenger untranslatable[3,6]. There is considerable evidence, however, in favour of the presumption that *in vivo* transcription requires neither translation nor ribosome movement[17,18]. It is possible that RNA polymerases progresses beyond the nonsense codon, but that the progress of mRNA synthesis along the region of DNA beyond the nonsense mutation site might be inhibited when the RNA polymerase is enveloped by the internal untranslatable messenger segment free of ribosome[18]. The polymerase molecules entangled with the messenger segments would stick on DNA and jam the region beyond the nonsense codon, thereby inhibiting the progress of the polymerase molecules that follow.

RNA polymerase might perhaps be rescued from messenger envelopment by attachment of ribosomes (or subunits) to the internal messenger segment growing behind the RNA polymerase, even if these ribosomes cannot start to translate the messenger segment because the latter contains no reinitiator signal. The probability that the untranslatable messenger segments overtake the polymerase before the next reinitiator for polypeptide synthesis, where surviving messengers are reloaded, would be proportional to the length of the untranslatable region. The gradient of polarity reflects the frequency with which the polymerase avoids these crises.

Before these hypotheses can be critically examined, the characteristics of normal and abnormal transcription termination should be elucidated in order to arrive at a more complete understanding of the regulatory mechanisms in transcription.

I thank Drs C. Yanofsky, E. P. Geiduschek and D. E. Morse for reading this manuscript and for criticism.

Chain Termination of Ribosomal RNA Synthesis *in vitro*

by

DAVID E. PETTIJOHN
O. GORDON STONINGTON
CHARLES R. KOSSMAN

Department of Biophysics,
University of Colorado Medical Center,
Denver, Colorado 80220

An RNA chain termination event in highly purified systems of polymerase and template is as precise as it is *in vivo*. Polyacrylamide gel electrophoresis analysis suggests that other protein factors such as the ρ-factor are not involved in this process.

During the transcription *in vitro* of certain bacteriophage DNAs, the DNA dependent RNA polymerase frequently terminates its synthesis, and in the appropriate conditions releases its RNA product and reinitiates a new cycle of RNA synthesis[1–5]. The chain termination occurs in highly purified systems, apparently without the participation of macromolecules other than the polymerase and its DNA template. It is not clear whether the termination is random on the DNA template or whether it occurs at specific sites similar to those used *in vivo*. When the termination factor ρ is added, the RNA products are of smaller length and are transcripts of more limited regions of the DNA template corresponding to the early and pre-early *in vivo* mRNA species[3,6]. Thus it seems that the ρ-factor mediates a biologically meaningful termination of RNA synthesis. The question remains whether there are other, more basic interactions, between the core RNA polymerase and certain sites or regions on the DNA which lead to the termination of RNA chains in the cell without the involvement of an independent termination factor.

Recently, we have found that ribosomal RNA (rRNA) can be preferentially synthesized *in vitro* on DNA complexes purified from *E. coli*[7,8]. The synthesis occurs as an extension of nascent rRNA chains isolated with the complex and new chains are not initiated[7,8]. The RNA polymerase molecules on the complex have initiated synthesis in the cell, and therefore they should be correctly started on the template. The system would seem to be well suited for studies of rRNA chain termination.

As described below, RNAs of discrete sizes are synthesized in this *in vitro* system, and the major product is homogeneous in polyacrylamide gel electrophoresis. The electrophoretic mobility of the latter RNA is indistinguishable from a labelled RNA obtained from pulse labelled cells. These results suggest that the synthesis of at least

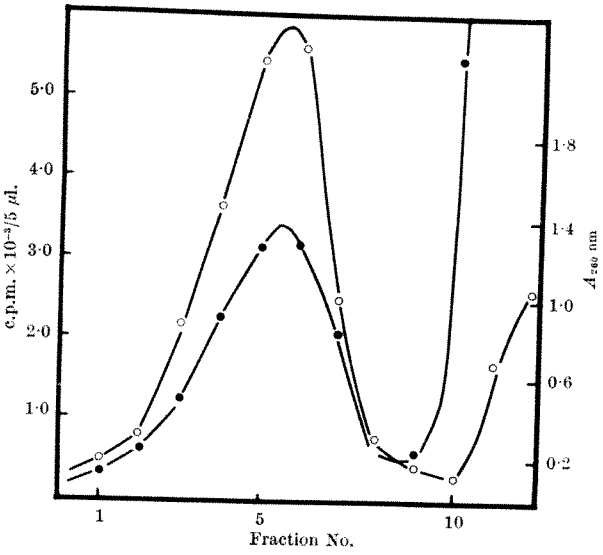

Fig. 1. Isolation of the DNA complex on a sucrose gradient. A culture of D-10 (90 ml.) growing in the log phase was pulse labelled for 10 s with 5-³H-uridine (100 μCi, 8 Ci/mM), quick chilled to 0° C while adding sodium azide to a final concentration of 10 mM, and was rapidly harvested by centrifugation. The bacteria were resuspended at 0° C in 0·2 ml. of a solution containing 20 per cent w/v sucrose, 0·01 M Tris (*p*H = 8·1 at 4° C), 0·1 M NaCl and then mixed with 0·05 ml. of a solution containing 50 mM EDTA, 5 mg/ml. lysozyme, 0·12 M Tris (*p*H = 8·1). After 30 s at 0° C, 0·25 ml. of a solution containing 1 per cent brij 58, 0·4 per cent deoxycholate, 10 mM EDTA and 2·0 M NaCl was added. The mixture was held for about 3 min at 0° C, during which time it cleared considerably but did not become more viscous. The lysate was centrifuged 5 min at 4,000*g* and 4° C to remove debris and the supernatant was layered on a 10–30 per cent w/v sucrose gradient containing 1·0 M NaCl, 0·01 M Tris (*p*H = 8·1 at 25° C), 1 mM EDTA and 1 mM β-mercaptoethanol. Centrifugation was at 17,000 r.p.m. for 10 min at 4° C in an SW50 rotor. The entire procedure was completed within 50 min. ○, Acid precipitable radioactivity; ●, absorbance.

some RNA species is precisely chain terminated *in vitro* at sites or regions on the DNA template similar to those used *in vivo*. It cannot be positively excluded that termination factors bound to the purified complex are responsible for the observed termination, but we can find little evidence of them. Analysis of the proteins of the complex by acrylamide gel electrophoresis reveals that they are predominantly RNA polymerase and from these data we estimate that there can be no more than one molecule of ρ-factor per 40 RNA polymerase molecules (of 13S size).

Preparation and Properties of the DNA Complex

The DNA complex was purified from *E. coli* strain D-10 (ribonuclease I⁻) (ref. 9) by a modification of our previous methods[8] and using some of the lysis procedures developed for the preparation of polyribosomes[10]. The purified complex is about 10 per cent protein by weight and includes nearly all of the DNA and DNA-bound RNA polymerase activity of the cell free lysate[8]. As shown in Fig. 1, nascent RNA chains (identified by pulse labelling the bacteria with ³H-uridine just before lysis) are bound to the complex. Only a small fraction of the pulse labelled RNA sediments free of the complex at the top of the sucrose gradient. This released fraction becomes much larger when the period of labelling is longer. Lysis at a low temperature and minimum preparation times are essential to obtain high yields of undegraded nascent chains on the complex. In general, the precautions are similar to those in preparing undegraded polyribosomes[10]. The DNA of the complex does not have the usual hydrodynamic behaviour of purified DNA, but seems to be folded into a compact structure (sedimentation coefficient is about 4,000S). The physical–chemical properties of this complex will be described in a future communication.

A large fraction of the RNA polymerase on the purified complex is bound to rRNA cistrons; when the complex is incubated in an assay mixture for RNA polymerase, the RNA synthesized is 45 ± 5 per cent rRNA[8]. The rate of synthesis and amount of RNA synthesized is independent of ionic strength[8] in the range 0·20 to 1·2 and is not influenced by agents that inactivate non-initiated RNA polymerase such as heparin[7].

RNA Molecules of Discrete Sizes are Synthesized

RNA was synthesized on the isolated DNA complex, purified and analysed by electrophoresis on acrylamide gels (Fig. 2). The period of synthesis (20 min) was sufficient to complete the reaction[8]. Because rRNA is guanosine rich, approximately 55 per cent of the incorporated ³H-GMP is in rRNA[8]. Two major species of RNA are resolved, both of lesser electrophoretic mobility (larger molecular weight) than the mature 23S rRNA marker. The smaller of these two RNAs appears to be as homogeneous in molecular weight as the mature rRNA markers (see also Fig. 3), while the larger may be somewhat heterogeneous. Only a small fraction of the total RNA product passes through the 2·8 per cent gel to become concentrated in the 7 per cent gel, showing that little of the RNA product is of sizes smaller than 16S rRNA. The mRNA sequences which were synthesized on the complex would be expected to be heterodisperse in size, because there are many different species and the nascent mRNA may be in various stages of degradation[12,13]. These mRNA sequences are probably distributed throughout the gel to account, at least in part, for the high backgrounds and the incomplete resolution of the major peaks.

Another method of labelling the RNA, which consistently gave lower backgrounds and better resolution of the RNA bands, is described in Fig. 3. In this case the nascent RNA on the complex was labelled *in vivo* before isolating the complex and then chains were completed *in vitro* using non-radioactive substrates. As shown in Fig. 3*b*, the same two RNA species as described in Fig. 2 were obtained. In addition, RNA species of mobilities similar to mature 23S rRNA (m23) and the 16S rRNA precursor (p16) (refs. 14–17) are observed. These latter

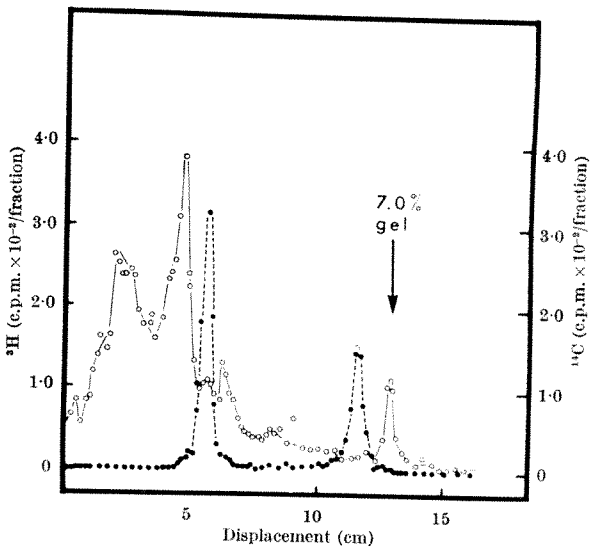

Fig. 2. Polyacrylamide gel electrophoresis of RNA synthesized *in vitro*. DNA complex was isolated from non-radioactive bacteria as described in Fig. 1. A reaction mixture (0·50 ml.) containing 18 μg of the purified complex, 0·02 M Tris (*p*H = 7·8 at 37° C), 12 mM $MgCl_2$, 1 mM EDTA, 1 mM β-mercaptoethanol, approximately 20 per cent w/v sucrose, 1·0 M NaCl, 0·15 mM ³H-GTP (0·6 Ci/mM) and 0·4 mM each of ATP, CTP and UTP was incubated for 20 min at 37° C. The RNA was purified[8], precipitated with ethanol, resuspended in buffer E (containing 0·04 M Tris, 0·02 M sodium acetate, 1 mM EDTA, 0·2 per cent SDS, *p*H = 7·2) and after the addition of sucrose to 20 per cent, it was layered into one slot in a slab of 2·8 per cent polyacrylamide gel overlaid on a slab of 7·0 per cent gel. The gels were made up in buffer E as described by Bishop *et al.*[11], run for 73 V h cm^{-1}, sliced, the slices dissolved in 30 per cent H_2O_2 and counted in an aqueous scintillation reagent. ● - - - ●, 23S and 16S ¹⁴C-rRNA markers (0·25 μg total) run in a separate slot of the same gel; ○—○, ³H-RNA synthesized *in vitro*, 3×10^4 applied (approximately 1 μg) mixed with 8 μg tRNA carrier.

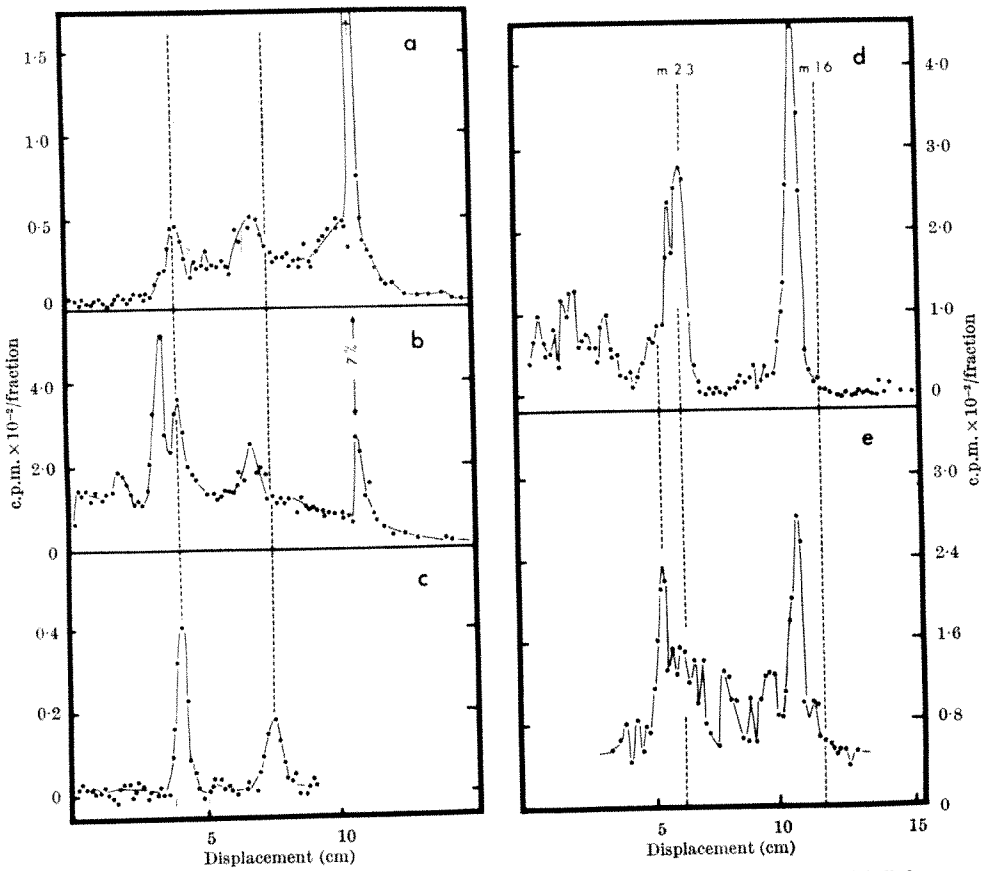

Fig. 3. Electrophoresis on polyacrylamide gel of RNA labelled *in vivo* and of nascent chains labelled *in vivo* and completed *in vitro*. A DNA complex was isolated from bacteria which had been pulse labelled as described in Fig. 1 except that ^{3}H or ^{14}C-guanosine was used. The RNA was purified from the complex and analysed by electrophoresis as described in Fig. 2. *a*, ^{3}H-RNA isolated directly from a portion of the purified complex, duration of pulse label 15 ± 3 s; *b*, ^{3}H-RNA from another portion of the same complex as used in *a* which had been incubated with non-radioactive ATP, CTP, UTP and GTP in a reaction mixture which was otherwise identical to that described in Fig. 2; approximately 3·5 times the amount of ^{3}H-RNA was applied as in *a*; *c*, ^{14}C-rRNA marker (23S and 16S) which were mixed with the RNA of *a*; *d*, released ^{14}C-RNA extracted from fractions 10, 11 and 12 (see Fig. 1) of another preparation which was pulse labelled for 90 s with ^{14}C-guanosine; *e*, nascent ^{14}C-RNA isolated from a complex which had been purified from bacteria which were pulsed for 10 ± 3 s with ^{14}C-guanosine. *a*, *b* and *c* were run on the same gel slab for 53 V h cm^{-1}. *d* and *e* were run on separate gels for 73 V h cm^{-1}; the dotted lines show positions of rRNA markers run together on the same gels. In *a* and *b* the peaks at the discontinuity between the 2·8 per cent and 7 per cent gels are due to concentration at the interface of small molecular weight RNA.

RNAs, however, were neither synthesized nor chain terminated *in vitro*. This is shown by two lines of evidence: (1) we never observe incorporation *in vitro* of a labelled ribonucleotide into RNAs which give well defined electrophoresis bands at the mobilities of p16 or m23 (see Fig. 2, for example); (2) the p16 and m23 molecules are present on the complex before the *in vitro* synthesis (see Figs. 3*a* and 3*e*, for example). Apparently, some newly terminated RNA molecules are retained on the complex; perhaps because there is delay in the normal release after termination or perhaps some newly released RNA is trapped within the folded DNA of the complex.

Relationship to RNA synthesized *in vivo*

The electrophoresis profiles of RNA synthesized *in vivo* which is released from the DNA complex or retained on the complex are shown in Figs. 3*d* and 3*e* respectively. The released RNA labelled during a 90 s pulse has a distribution similar to that previously reported for total pulse labelled RNA[14–17]. Prominent is the m23 rRNA band as well as the rRNA precursor bands p23 and p16 which have mobilities slightly less than m23 and m16, respectively. The RNA retained with the complex following the 10 s pulse label is more heterodisperse, as expected, because this RNA includes nascent chains. The broad distribution in the region of the 23S rRNA marker is strongly weighted toward mobilities smaller than m23 and has a peak at a mobility somewhat less than p23. This peak has only been seen after very short pulse labels; frequently, it is not as well defined as in Fig. 3*e* and appears only as a shoulder on the low mobility side of m23 as in Fig. 3*a*. With longer periods of labelling the m23 band becomes so prominent that it obscures this RNA species. The mobility of this RNA is very close to that of the major RNA species which is chain terminated *in vitro* (see Fig. 4), suggesting that at least one of the RNA species synthesized *in vitro* may be of the same size as a labelled RNA synthesized in the cell. It should be pointed out that pulse labelled RNA such as that described in Fig. 3 is predominantly labelled in rRNA sequences[8,18,19]. It is therefore unlikely that any single mRNA species would give rise to bands of peak heights comparable with those of rRNA.

Estimated Molecular Weights

The relative electrophoretic mobility of RNA on polyacrylamide gel is linearly related to the logarithm of its molecular weight[11]. In Fig. 4 the mobilities of the *in vitro* synthesized RNAs are compared with the known rRNAs m23, m16, p23 and p16. These data indicate that the two major RNA species which are chain terminated *in vitro* on the protein–DNA complex have molecular weights of $1{\cdot}25 \times 10^{6}$ and $1{\cdot}7 \pm 0{\cdot}15 \times 10^{6}$ daltons. The error range of the larger RNA reflects the possible heterogeneity in the electrophoresis band. The molecular weights of the p23 and p16 species from the same data

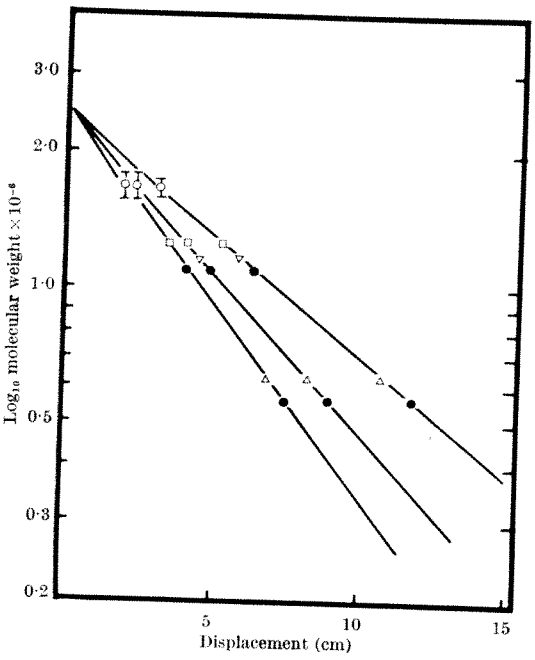

Fig. 4. Estimation of molecular weight of *in vitro* RNA products and *in vivo* rRNA precursors. The relative electrophoretic mobilities of various RNAs compared with mature rRNA markers are plotted. Three independent determinations taken from the data of Fig. 3 as well as two other experiments are shown above. ●—●, 23S rRNA and 16S rRNA taken as $1{\cdot}1 \times 10^6$ and $0{\cdot}56 \times 10^6$ daltons respectively; △, p16 synthesized *in vivo*; ▽, p23 synthesized *in vivo*; □ and ○, the two major RNAs synthesized *in vitro*.

are $1{\cdot}17 \times 10^6$ and $0{\cdot}62 \times 10^6$ daltons, respectively. The above figures are relative to m23 and m16 markers which may have slight anomalies in their mobilities[11].

Proteins of the Purified Complex

The finding that RNAs of discrete sizes are synthesized on the purified DNA complex suggests that precise chain termination events occur during the synthesis. We have tried to bring evidence to bear on the possibility that factors other than the RNA polymerase and DNA of the complex participate in this termination. The conditions of isolation of the complex are quite demanding in that only molecules sedimenting at $4{,}000 \pm 500$S are selected. Molecules bound to the complex must remain tightly associated in the presence of 1·0 M NaCl. The known proteins of *E. coli* which bind to DNA are dissociated at these high ionic strengths[20]; only RNA polymerase which has initiated synthesis is known to be an exception[21,22]. In addition, the conditions of synthesis are such that any chain termination factor must be active at ionic strengths greater than 1·0 in order to influence the size of the products. The ρ-factor is known to be inactive at ionic strengths greater than 0·15 (ref. 23).

The proteins of the purified complex have been isolated and analysed on polyacrylamide gels in the presence of SDS (Fig. 5). The major bands correspond to the α, β and β′ subunits of RNA polymerase[26,27]. Little or no σ-factor protein is observed, which is consistent with previous findings *in vitro*[28,29] that the σ-factor is released from the RNA polymerase core after initiation. Our results suggest that the σ-factor also recycles *in vivo* on the *E. coli* DNA template. The fractionation described in Fig. 5 reveals only one minor protein component other than those of RNA polymerase; but when the gels are overloaded with protein (approximately ten-fold greater in amount than in Fig. 5*b*) several additional minor bands do appear. The largest of these in the region of the gel between α and σ (the region expected for the ρ-factor[3]) had a scanning area less than 0·06 of that of α. If we assume that the ratio of stain to protein is the same for all proteins in the region of α, the published values for molecular weights and subunit compositions of rho[3] and RNA polymerase[26,27], then we estimate that less than one ρ-factor per 40 RNA polymerase (13S size) molecules is on the complex.

These results are in agreement with those of Millette[30], who has shown that the major transcription product of purified RNA polymerase on T7 DNA template is a single homogeneous RNA. In this work it was estimated that the amount of ρ-factor contaminating the RNA polymerase preparation was less than one ρ-factor per 50 polymerase molecules. Also, Roberts[3] has observed RNA chain termination at specific regions of λ DNA templates in the absence of added ρ-factor. It therefore seems likely that there is one kind of chain termination in which RNA polymerase recognizes certain sites on its DNA template and, independent of other components, specifically terminates its synthesis. There are probably then, at least two different processes in the cell for RNA chain termination.

Ribosomal RNA Synthesis

As presented in this communication, the relationship of the RNA species synthesized *in vitro* to rRNA synthesis is circumstantial. That is, we depend on previous findings that the primary product of the *in vitro* system is rRNA[8].

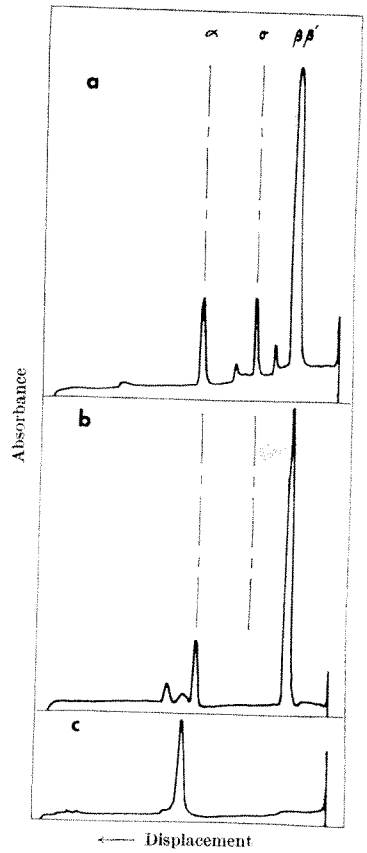

Fig. 5. Polyacrylamide gel electrophoresis of the proteins from the purified DNA complex. The DNA complex, isolated by a scaled-up modification of the procedure described in Fig. 1 (to obtain larger amounts of complex), was degraded with pancreatic deoxyribonuclease and applied to a 'Biogel P-4' column. Material alluting with the excluded volume was lyophilized, redissolved in a buffer containing 0·01 M sodium phosphate (*p*H 7·2), 0·1 per cent SDS, 0·14 M β-mercaptoethanol, heated for 10 min at 65° C, and run for 20 V h cm^{-1} on 5 per cent polyacrylamide gels as described by Shapiro *et al.*[24]. The gels were stained with coomassie blue, destained with trichloroacetic acid, and scanned with a Densicord recording electrophoresis densitometer which had been calibrated with protein standards in gels to give band areas linearly related to protein concentration. Direct tracings of the actual scans are shown above. The β and β′ bands which were visually distinct were not resolved by the densitometer. *a*, RNA polymerase (5 μg) purified by the double glycerol gradient method of Burgess[25]; the minor band between β and σ is the commonly observed contaminant τ[26,27]; the minor band between σ and α is another contaminant. *b*, Proteins isolated from the purified complex (about 5 μg); the two minor bands to the left of α are, respectively, deoxyribonuclease added to degrade the complex and a non-RNA polymerase protein present with the complex. *c*, Pancreatic deoxyribonuclease run in a separate gel.

Recently, however, we have isolated the RNA of the two major electrophoresis bands (as in Fig. 2) and observed that this RNA can compete with rRNA during DNA–RNA hybridization. These experiments will be described in a future publication.

The overall significance of the observation that rRNA synthesized *in vitro* is larger than the known rRNA precursors is not yet clear. The smaller of the *in vitro* rRNAs is similar in electrophoretic mobility to a labelled RNA obtained from pulse labelled bacteria, suggesting that it may correspond to an rRNA precursor synthesized in the cell. This ostensible precursor is about 7 per cent larger than the p23 rRNA precursor previously reported[15–17] and observed here. 23S rRNA may be the product of at least two steps of maturation similar to the 16S rRNA for which two precursor steps are indicated[16]. The *in vitro* rRNA of $1{\cdot}7 \pm 0{\cdot}15 \times 10^6$ daltons cannot yet be correlated with known rRNA precursors. Two possible explanations for this RNA have occurred to us: (1) It may result from polymerase molecules which pass a termination signal and respond thereafter to an adjacent termination site. This might happen, for example, if the missed site is one requiring an independent termination factor such as the ρ-factor. (2) In the cell the "unit of transcription" for rRNA may include both the sequences of 16S and 23S rRNA and the primary transcription product may be cleaved before the completion of its 3′ end by a specific nuclease into sequences containing only p23 or p16. Thus polymerase molecules which had not passed the "cleavage region" or which missed the termination site on the DNA complex would synthesize large precursors *in vitro*, while those which had passed the region would synthesize the smaller rRNA molecules of molecular weight $1{\cdot}25 \times 10^6$ daltons. These considerations are consistent with the relative sizes of the observed rRNA molecules, that is, the sum of the molecular weights of p16 and the smaller *in vitro* rRNA are about equal to that of the larger *in vitro* rRNA. Either of these two considerations could also explain the observation that while the sequences of 16S rRNA are synthesized *in vitro*[8], molecules of the size of p16 or m16 are not. It would then be required that the 16S rRNA region of the primary transcription product always occurs on the 5′ side of the cleavage region or missed termination site. It is pertinent to this discussion that the 23S and 16S rRNA genes are very closely linked and probably alternating in *B. subtilis*[31] (which is similar to *E. coli* in many aspects of rRNA synthesis and maturation[15]). Furthermore, either of the above explanations predict that the fraction of an incorporated radioactive label which appears in the larger rRNA synthesized *in vitro* will be less when labelling occurs *in vivo* (as in Fig. 3*b*) than when the label is incorporated *in vitro* (as in Fig. 2). We have consistently observed this predicted difference (for example, the experiments of Figs. 2 and 3*b*).

We thank Miss Kathleen Clarkson for technical assistance and Drs Norman Pace and Robert Millette for helpful discussion. This work was supported by a research grant from the US National Institutes of Health, and by a US Public Health Service training grant from the National Institute of General Medical Sciences. Two of us (O. G. S. and C. R. K.) are predoctoral trainees of the US Public Health Service.

Selective Binding of Ribosomes to Initiation Sites on Single-stranded DNA from Bacterial Viruses

by
GARRET IHLER
DAI NAKADA
Department of Biochemistry,
University of Pittsburgh,
School of Medicine,
Pittsburgh, Pennsylvania 15213

Bacterial ribosomes can bind to initiation sites on single-stranded DNA acting as messenger. Factors are synthesized during phage development which are required for binding to late gene sites but not to early gene sites. They may be involved in the control of translation.

Ribosomes are known to bind to specific sites on mRNA. For example, in the presence of protein initiation factors, f-Met-tRNA$_f$, and the proper Mg^{2+} concentration, ribosomes bind only to the three sites on R17 phage RNA which are used as initiation sites *in vivo* for polypeptide synthesis[1]. Each binding site contains the triplet AUG which has been shown to code for the first amino-acid incorporated into protein, N-formyl-methionine[2]. The triplet AUG is not sufficient by itself to create an initiation site because many internal AUG triplets exist which are not used as initiation sites. Some other feature, possibly the nucleotide sequence and secondary structure around the initiation triplet, must also be involved in the recognition of the true initiation region by the ribosome and initiation factors. Single-stranded DNA can function as a template for the incorporation of amino-acids into

protein in the presence of the antibiotic neomycin. Neomycin, however, appears to be necessary only for the extensive incorporation of amino-acids. The binding reaction between factors, ribosomes, tRNA and single-stranded DNA to form the initiation complex does not require neomycin[4,5] and short oligopeptides can be synthesized in the absence of neomycin[6].

Do ribosomes bind to the specific sites on single-stranded DNA that correspond to initiation sites on mRNA? Because mRNA is a complementary copy of one of the two strands of DNA, one strand of DNA contains the base sequences corresponding to those in mRNA which constitute the binding sites, except that thymine is substituted for uracil and therefore mRNA and single-stranded DNA may have in common whatever features constitute the binding site. If so, the use of DNA as an analogue for mRNA would facilitate study of the initiation complex because DNA can be readily isolated in a pure, undamaged form from phage particles whereas mRNA must either be isolated from the cell as a heterogeneous and partly degraded mixture of phage and bacterial mRNA species or synthesized *in vitro* using RNA polymerase. Neither of these two procedures is entirely satisfactory at present.

A long standing problem of intracellular phage development is the time-dependent changes in protein synthesis that occur after infection. Some phage-induced proteins are synthesized early after infection (early proteins) while the synthesis of others (late proteins) is delayed. Recent studies have demonstrated that there are several categories of phage-specific mRNA formed after infection. The host sigma factor and host RNA polymerase are used for the synthesis of the first mRNA species[7,8]. RNA species synthesized later depend on the synthesis of a new phage-specific sigma factor which, with the host "core" RNA polymerase, initiates transcription of these RNA species[9,10].

While transcriptional control by sigma factors is sufficient to explain the early–late phenomenon, recent work has suggested that there may be some form of translational control as well. It was found that ribosomes from T4-infected cells are unable to translate messenger obtained from RNA phages, although they translate T4 mRNA, and that this effect is connected with the synthesis of one or more new T4-induced proteins[11,12]. Translational control might plausibly be expected to occur at the initiation step. For example, *E. coli* ribosomes might be unable to bind to initiation sites for late T4 messengers unless modified, possibly by the synthesis of new binding factors, during the course of phage development.

We show here that *E. coli* ribosomes bind selectively to only one of the two separated strands of T7 DNA, that strand which contains within it sequences corresponding to initiation sites in T7 mRNA. We cannot discriminate in these experiments between early and late T7 genes. With phage T4, however, we can show that ribosomes from uninfected cells will bind to DNA containing sequences corresponding to initiation sites on early messenger but not to such sequences for late messenger. Preliminary results indicate that ribosomes from T4-infected cells do bind to DNA containing initiation sequences for late messenger.

Purification of Single-stranded DNA

The individual strands of DNA obtained from T7, lambda and T4 bacteriophage particles were purified by complexing the denatured DNA with poly rU,G. One of the two strands has been shown to bind more poly rU,G and to have, therefore, a greater buoyant density in CsCl than its complement[13] (Fig. 1*a*). We will use the term "heavy" to refer to the DNA strand which bands at the greater density and "light" to refer to the complementary strand without regard to the species of DNA used or whether it contains early genes, late genes or both. Poly rU,G contains GUG sequences which function

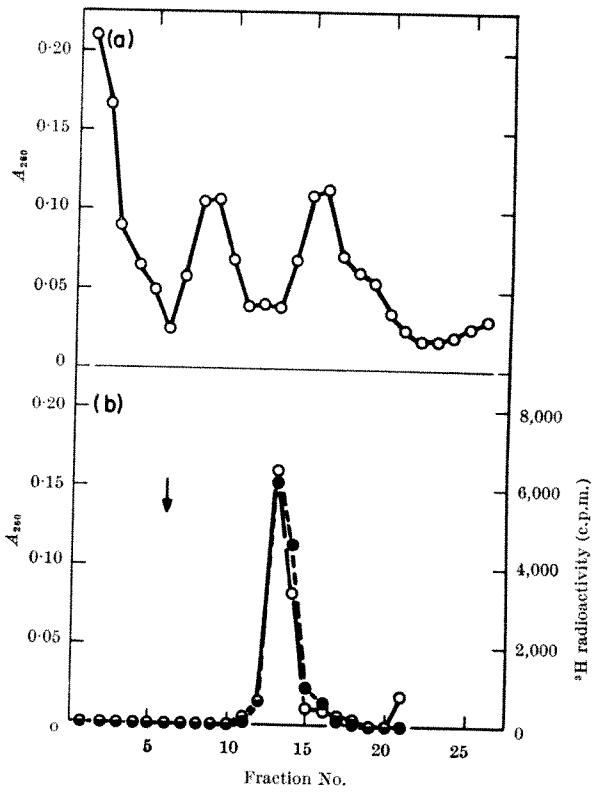

Fig. 1. Equilibrium CsCl density gradient centrifugation of T7 DNA. *a*, Separation of heavy and light strands of T7 DNA. 10^{13} T7 phage particles were dialysed against 0·02 M Tris buffer (*p*H 7·4) and 0·01 M NaCl in a volume of 0·5 ml. EDTA to 0·01 M and Sarkosyl to 0·1 per cent were added and the phage particles were lysed by heating at 60° C for 30 min. NaOH to 0·2 M was added to denature the DNA. The solution was diluted to 4·5 ml. with 0·05 M Tris (*p*H 7·4) and enough 1 M HCl was added to neutralize 90 per cent of the NaOH. One mg of poly rU,G (Miles) was added, followed by solid CsCl (Harshaw) to a refractive index at 1·4052. The solution was centrifuged for 60 h in the Spinco fixed angle 65 rotor at 18° C, 35,000 r.p.m. One-tenth of each fraction (20 μl.) was used to determine the A_{260}. *b*, Rebanding of heavy strands of T7 DNA after alkaline hydrolysis. Heavy strands of T7 DNA were dialysed in 0·01 M Tris (*p*H 7·9), 0·001 M EDTA and 0·01 M NaCl. NaOH (1M) was added to a final concentration of 0·2 M and the DNA was incubated at room temperature for 24 h. The NaOH was neutralized with Tris-HCl buffer and dialysed in 0·005 M Tris (*p*H 7·9) and 0·0005 M EDTA. The DNA was then mixed with denatured ^{3}H-T7 DNA, and CsCl was added to a refractive index at 1·4033. Both heavy and light strands banded at the same density after alkaline hydrolysis relative to denatured ^{3}H-T7 DNA, centrifuged either in the same gradient or in separate gradients. (*a* and *b* are not directly comparable because of the different initial densities.) The arrow indicates the position of the heavy DNA after denaturation and prompt neutralization which was ineffective in removing bound poly rU, G. ○—○, A_{260} of heavy strands of T7 DNA; ●– – –●, radioactivity of denatured ^{3}H-T7 DNA.

as well as AUG sequences for the formation of complexes with ribosomes and f-Met-tRNA$_f$ (ref. 14), and therefore it was necessary to remove the residual poly rU,G present both bound and unbound to the DNA. We first attempted to do this by exposing the DNA to denaturing conditions (0·2 N NaOH for 5 min) followed by banding in CsCl. The DNA, however, banded at a higher density than denatured T7 DNA, indicating that the treatment did not remove bound poly rU,G. Alkaline hydrolysis (0·2 N NaOH for 24 h at room temperature) was sufficient to hydrolyse the poly rU,G. After hydrolysis, both strands now banded at the same density in CsCl as denatured T7 DNA which had not been exposed to poly rU,G (Fig. 1*b*). Using poly rU,G (1 : 3) obtained from Schwartz Bioresearch, it was necessary to treat the DNA solutions further after alkaline hydrolysis with ribonuclease (0·1 μg/ml.) for 15 min at room temperature. The ribonuclease activity was then destroyed by a brief re-exposure to 0·2 N NaOH. We found that ribonuclease alone, without alkaline hydrolysis, was insufficient to destroy all the poly rU,G.

Table 1. SINGLE-STRANDED PHAGE DNA-SPECIFIC BINDING OF ^{14}C-f-Met-tRNA$_f$ TO RIBOSOMES

Nucleic acid added	^{14}C-f-Met-tRNA$_f$ bound pmoles	Δ pmoles	Binding sites per single-stranded nucleic acid
—	0·95	—	—
MS2 RNA, 7 μg	3·82	2·87	0·41
T7 DNA, light strand 4·7 μg	2·98	2·03	5·18
T7 DNA, heavy strand 4·7 μg	0·93	—	—
T7 DNA, native double strands 9·5 μg	1·01	0·06	—
λ DNA, light strand 4·7 μg	2·00	1·05	3·69
λ DNA, heavy strand 4·7 μg	1·87	0·92	3·23

The reaction mixture in the presence of 5 mM Mg^{2+} was incubated at 35° C for 15 min and radioactivity retained by a 'Millipore' filter was counted[16]. The reaction mixture, in a total volume of 0·4 ml., contained: 100 μg NH_4Cl-washed ribosomes from *E. coli* 238 cells (endonuclease$^-$); 10 μg crude initiation factors; 6,000 c.p.m. ^{14}C-f-Met-tRNA$_f$ (150 c.p.m. = 1 pmole); 20 μmoles of Tris (pH 7·2) and 2 μmoles of magnesium acetate; 20 μmoles of NH_4Cl; 0·1 μmole of GTP. Nucleic acid was added as indicated. All single-stranded DNAs used in this and following experiments were treated with alkaline hydrolysis and ribonuclease.

Binding of Ribosomes to Single-stranded DNA

We have used single-stranded DNA from phage T7 to demonstrate specific binding of ribosomes. All the mRNA transcribed from T7 DNA *in vivo* has been shown to be complementary to only the heavy strand of the DNA[15]. Consequently we would expect the light strand to contain all the sequences corresponding to T7 mRNA and therefore to contain all the ribosome binding sites. The experiments described in Table 1 show that the light strand but not the heavy strand of T7 DNA on a 'Millipore' filter retains significant amounts of radioactive f-Met-tRNA$_f$ (ref. 16). The amount of f-Met-tRNA$_f$ retained is roughly proportional to the amount of nucleic acid added. Single-stranded DNA was specifically required, for no binding was detected using native double-stranded T7 DNA (Table 1). Retention was not affected by ribonuclease treatment, but was completely abolished by deoxyribonuclease, indicating that the ribosome was bound to DNA (Table 2*a*). Retention was dependent on the addition of ribosomes and on the presence of protein initiation factors known to be required for the formation of specific initiation complex with mRNA (Table 2*b*). No binding was detected using three other radioactive aminoacyl tRNAs, Lys-tRNA, N-acetyl-Phe-tRNA and Phe-tRNA, indicating that the complex forms specifically with f-Met-tRNA$_f$ (Table 2*c*).

We believe that the heavy strand of T7 DNA does not bind f-Met-tRNA$_f$ in a complex with ribosomes because it lacks the specific sites needed for ribosome binding. One alternative explanation might be that the heavy strand does not contain any ATG triplets (which are needed for complementary interaction with the anti-codon site of f-Met-tRNA$_f$). This possibility is unlikely because we found that both strands of T7 DNA bind met-tRNA equally when the Mg^{2+} concentration is raised (Table 2*d*). It is known that at high Mg^{2+} concentrations, ribosomes can bind non-specifically to many sites on mRNA, although the codon specificity for the tRNA is retained[17]. We conclude, therefore, that the heavy strand of T7 DNA must indeed contain ATG sequences which can be recognized in the abnormal conditions of high Mg^{2+} concentrations.

Phage lambda, unlike phage T7, used both strands of DNA for the synthesis of mRNA, some mRNA molecules being derived from the heavy strand and some from the light strand. Early mRNA in particular is known to be derived from both strands[18]. We would therefore predict that both heavy and light strands of lambda DNA should bind ribosomes and f-Met-tRNA$_f$. This prediction was confirmed by the experiment shown in Table 1 where it can be seen that both strands cause the retention of equal amounts of f-Met-tRNA$_f$. Thus, in agreement with the expectation, with one phage, T7, only one strand participated in complex formation while with another, lambda, both strands participated.

Early messengers of phage T4 are transcribed from the heavy strand and late messengers from the light strand[19]. Consequently, the ribosome binding sites for late genes are contained primarily in the heavy DNA strand. Using ribosomes, factors and f-Met-tRNA$_f$ from uninfected cells, we found that the heavy strand (late genes) fails to bind f-Met-tRNA$_f$ while the light strand (early genes) does bind f-Met-tRNA (Table 3*a*). This implies that some new component must be synthesized during phage development to allow ribosomes to bind to initiation sites for late genes. We have conducted some preliminary experiments to test this possibility. Using unwashed ribosomes isolated 22 min after infection with T4 phage, we found that these ribosomes can bind to the heavy strand (late genes) but cannot bind to the light strand (early genes). These ribosomes also do not bind well to MS2 RNA (Table 3*b*).

From the known specific activity of the radioactive f-Met-tRNA$_f$ and the amount and molecular weight of the added DNA, we can estimate the number of binding sites per single strand. We find about 0·5 binding sites per MS2 RNA molecule, in general agreement with previous results showing that ribosomes can bind to only one initiation site on unfragmented MS2 RNA, that site being the coat protein gene[16]. We find about five sites on the light strand of T7 DNA (Table 1). This number is considerably smaller than the twenty-five to thirty known proteins[20] and also smaller than the twelve *in vivo* RNA species found[21]. It is, however, about equal to the number of early T7 genes transcribed in the absence of the T7-specific sigma factor[20]. We find three to four sites on the heavy strand of λ DNA and an equal number of sites on the light strand, again in rough agreement with the distribution of early genes between the two strands[18].

We found about twelve sites on the light strand (early genes) of T4 DNA using ribosomes and factors from

Table 2. SPECIFICITY OF PHAGE DNA-DIRECTED BINDING OF ^{14}C-f-Met-tRNA$_f$ TO RIBOSOMES

(*a*) Effect of deoxyribonuclease treatment

Nucleic acid added	^{14}C-f-Met-tRNA$_f$ bound, c.p.m. No deoxyribonuclease	Deoxyribonuclease treated
—	88	82
MS2 RNA, 7μg	426	340

λ DNA, heavy strand 2·3 μg	110	83	30	83

(*d*) Effect of Mg^{2+} concentrations

Nucleic acid added	^{14}C-f-Met-tRNA$_f$ bound, c.p.m. 5 mM Mg^{2+}	^{14}C-Met-tRNA bound, c.p.m. 20 mM Mg^{2+}
—	60	113
MS2 RNA, 5 μg	191	244
T7 DNA, light strand 2·3 μg	164	246
T7 DNA, heavy strand 2·3 μg	94	224

The reaction mixture in a total volume of 0·4 ml. in the presence of 5 mM Mg^{2+} was the same as described in Table 1 and incubated at 35° C for 15 min.

(*a*) Nucleic acid was treated with 0·1 μg deoxyribonuclease at 35° C for 10 min just before the reaction.

(*c*) 5 μl. each of ^{14}C-Lys-tRNA (1,400 c.p.m./μl.), ^{3}H-acetyl-Phe-tRNA (800 c.p.m./μl.) and ^{3}H-Phe-tRNA (1,100 c.p.m./μl.) was added where indicated instead of ^{14}C-f-Met-tRNA$_f$.

(*d*) At 20 mM Mg^{2+}, ^{14}C-Met-tRNA (5,000 c.p.m.; 90 c.p.m. = 1 pmole) was added instead of ^{14}C-f-Met-tRNA$_f$.

Table 3. T4 PHAGE DNA-SPECIFIC BINDING OF ^{14}C-f-MET-tRNA$_f$ TO RIBOSOMES

Source of ribosomes	Nucleic acid added	^{14}C-f-Met-tRNA$_f$ bound, pmoles	Δ pmoles	Binding site per single-stranded nucleic acid
(*a*) Uninfected cells	—	0·70	—	—
	MS2 RNA, 14 μg	7·16	6·46	0·46
	T4 DNA, light strand 4·7 μg	1·62	0·92	11·74
	T4 DNA, heavy strand 4·7 μg	0·72	0·02	—
(*b*) T4-infected cells	—	0·68	—	—
	MS2 RNA, 14 μg	1·31	0·63	0·045
	T4 DNA, light strand 4·7 μg	0·67	—	—
	T4 DNA, heavy strand 4·7 μg	1·26	0·58	7·40

Conditions for the reaction were the same as described in Table 1, except 5,000 c.p.m. ^{14}C-f-Met-tRNA$_f$ (100 c.p.m. = 1 pmole) was used. Single-stranded T4 DNAs used in this experiment were treated with alkaline hydrolysis and ribonuclease. Ribosomes (100 μg) washed with NH_4Cl and initiation factors (10 μg) were present in (*a*), and ribosomes (100 μg) prepared from T4-infected cells (22 min after the infection) and not treated with NH_4Cl were present in (*b*).

uninfected cells (Table 3*a*). There are at least twenty to twenty-five early genes in T4, which fall into several subdivisions of early proteins. It is not known whether all of these early proteins can be synthesized *in vitro* using factors from uninfected cells. Several T4 proteins which are, however, transcribed from the strand containing early genes have been synthesized *in vitro* using initiation factors from uninfected cells[22–24]. Most early proteins may use host initiation factors. Using ribosomes from T4-infected cells, we find less than ten sites on the heavy strand (late genes) of T4 DNA (Table 3*b*). This number is somewhat smaller than the number of late genes, which is about fifty.

We conclude that ribosomes can bind to specific sites in single-stranded DNA, presumably corresponding to initiation sites in mRNA, for ribosomes bind to the light strand of T7 DNA but not to the heavy strand. The experiments with T4 DNA suggest that ribosomes from uninfected cells bind only to initiation sites for early genes and that some new component is synthesized during phage development, allowing ribosomes to bind to initiation sites for late genes. Our results with ribosomes and factors obtained from T4-infected cells indicate that these ribosomes can bind to sites for late genes but not to sites for early genes.

We feel that the use of DNA rather than mRNA offers a simplified approach to several problems in addition to the question of translation control. Mutants of the *lac* operon have been isolated[25] which contain polypeptide reinitiation sites. By using transducing phages containing these sites, it should be possible to determine if these mutations create new ribosome binding sites. It may also be possible to sequence the binding sites and to investigate the mechanism of initiation of protein synthesis in mammalian systems using mammalian virus DNA.

We thank Mark Bretscher for informative discussions before the start of this work, Kivie Moldave for his support and encouragement, and Mona Inati for technical assistance. This work was supported in part by grants from the US Public Health Service and the Health Research Services Foundation, Pittsburgh.

Translation of a Purified DNA-RNA Complex

by
N. G. AVADHANI
D. E. BUETOW
Department of Physiology and Biophysics,
University of Illinois,
Urbana, Illinois 61801

A eukaryotic DNA–RNA complex, which seems to be a transcription complex, can be translated *in vitro* by a cell-free system from *E. coli*.

THE occurrence of a DNA–RNA complex in several strains of *Euglena gracilis* and in a related organism, *Astasia longa*, has been demonstrated in this laboratory, and methods for the isolation and purification of this complex have been reported[1–3]. Spiegelman, Hall and Storch[4] were the first to identify a DNA–RNA complex in viral infected *Escherichia coli*. On the basis of the experimental data then available, they postulated that the "complex" represented a stage of transcription during which specific "informational" RNA molecules were formed on the viral DNA template. Since then, a number of complexes containing RNA have been reported in many types of cell[5–10]. In most cases, the investigators either assumed or gave indirect evidence to show that the RNA contained in the complex was messenger RNA. Recently, Jachymczyk and Cherry[11] reported that a fraction of RNA from peanut seedlings containing free DNA and DNA–RNA stimulated the incorporation of amino-acids into trichloroacetic acid (TCA) insoluble material when added to a cell-free protein-synthesizing system. It is not clear from this study[11], however, whether the stimulation was due to the DNA–RNA (presumably a complex) or to the free DNA. The latter is possible because there are reports of DNA acting as a direct template for protein synthesis in some systems[12,13]. Here we demonstrate that a purified DNA–RNA complex from

E. gracilis and from *A. longa* is translated very efficiently in a cell-free protein-synthesizing system from *E. coli*.

Cells used were two photosynthetic forms (strain Z and variety bacillaris) of *E. gracilis*, a streptomycin-bleached, chloroplast-free strain (SM–L1) of *E. gracilis*, and the closely related, naturally colourless, chloroplast-free flagellate, *A. longa* (strain J). All cells were grown in the dark on a defined medium[14] as described[15]. In some experiments, the photosynthetic *Euglena* were also grown under constant light at room temperature on defined medium[14] without the carbon source (acetate).

The total RNA from all cell types was isolated by the phenol technique[15]. The isolated total RNA was extracted with 1·0 M NaCl to give "saline-soluble RNA", and the DNA–RNA complex was isolated from the latter by precipitation with isopropanol[1–3]. The composition of the complex from strain SM–L1 *Euglena* is 52 per cent RNA, 31 per cent DNA and 17 per cent protein[1,2].

The S-30 fraction from *E. coli* A19 was extracted and pre-incubated according to Clark *et al.*[16] except that the pre-incubation time was increased from 40 min to 60 min. The final preparation was stored as small aliquots in liquid nitrogen until used for amino-acid incorporation studies. Assays were run at 37° C in 0·05 ml. final volumes. Turnip yellow mosaic virus (TYMV) RNA was used as a standard and was prepared as described by J. M. Clark, jun. (personal communication).

Protein-synthesizing Activity

During the initial stages of standardization of the cell-free system, various parameters such as amounts of template RNA, of the S-30 fraction, and of the amino-acids were adjusted to arrive at optimal conditions. For TYMV RNA, the conditions used by Clark *et al.*[16] were found to be optimal. The TYMV RNA in these conditions[16], therefore, was used as a standard reference in subsequent experiments. For *Euglena*, 20–25 μg of total RNA and other RNA fractions (see tables) or 10 μg of DNA–RNA complex gave maximum activity when 0·02 ml. of the S-30 fraction was used. The activity of the system with either TYMV or various *Euglena* templates was dependent on the addition of ATP, GTP and twenty amino-acids. For example, omission of five L-^{12}C-amino-acids lowered the activity by about 75–80 per cent.

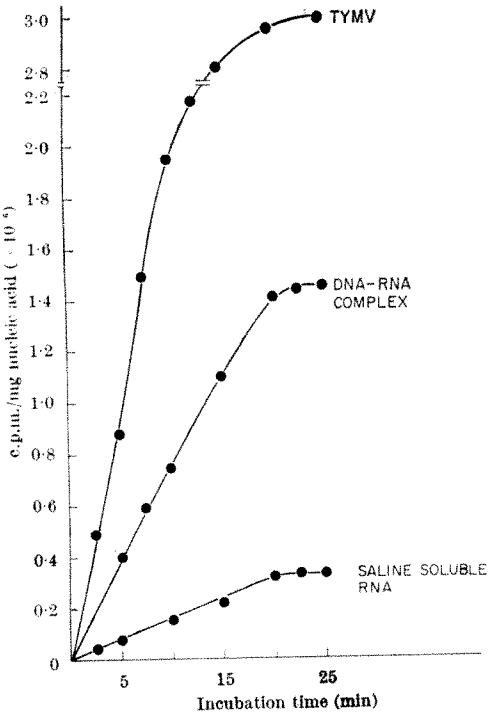

Fig. 1. Template activity and time of incubation of TYMV RNA and two fractions from strain SM–L1 *Euglena*. Details are given in Table 1.

Table 1. PROTEIN-SYNTHESIZING ACTIVITY OF RNA FRACTIONS FROM STRAIN SM–L1 *Euglena*

Fraction	c.p.m./mg nucleic acid
Total RNA	$6·0–8·0 \times 10^4$
Saline-insoluble RNA	$2·0–3·5 \times 10^3$
Saline-soluble RNA	$3·9–4·0 \times 10^5$
DNA–RNA complex	$1·3–1·5 \times 10^6$
TYMV RNA	$2·5–3·1 \times 10^6$

Assays were run at 37° C for 25 min in final volumes of 0·05 ml. The reaction mixture was modified from Clark *et al.*[16] and included the following: 0·04 M Tris-HCl (*p*H 7·8), 0·0125 M magnesium acetate · 4 H_2O, 0·04 M KCl, 0·01 M β-mercaptoethanol, 0·01 M NH_4Cl, 0·006 M phosphoenolpyruvate (Sigma), 0·0015 M ATP (Sigma), 0·003 M GTP (Sigma), 0·1 mM polyethylene glycol 4,000 (Union Carbide Chemical Co.), 0·5 μCi algal hydrolysate containing fifteen ^{14}C-amino-acids (New England Nuclear, 1·8 μCi/mg), 4×10^{-5} M each of L-^{12}C-amino-acids (asparagine, glutamine, tryptophan, methionine and cysteine), 2·5 μg of crystalline pyruvate kinase (Sigma), 0·01 ml. or 0·02 ml. of the S-30 fraction as desired and 0–40 μg of TYMV RNA or various fractions of *Euglena* RNA. The S-30 fraction was extracted from *E. coli* A19 and pre-incubated according to Clark *et al.*[16] except that the pre-incubation time was increased from 40 min to 60 min. The amount of radioactivity incorporated into the TCA-insoluble fraction was measured as described[16]. The blank—complete system minus added template—was usually between 600–900 c.p.m. for the 0·05 ml. system and was subtracted from the above values. The amounts of nucleic acid were determined by A_{260} readings (1·0 *A* unit = 40 μg).

Amino-acid incorporation by the TYMV RNA and by the DNA–RNA complex and the saline-soluble RNA from strain SM–L1 *Euglena* was maximal between 20 and 25 min (Fig. 1). In subsequent experiments, the time of reaction was therefore kept at 25 min. Total RNA isolated by our usual procedure[15] from strain SM–L1 *Euglena* had considerable activity and most of this activity was extractable in 1·0 M saline (Table 1). Saline-insoluble RNA had a low activity whereas the DNA–RNA complex exhibited about twenty times higher activity than the total RNA. Electrophoretic patterns of the total RNA, the saline-soluble fraction, and the DNA–RNA complex are shown in Fig. 2.

To locate the species of RNA molecules which incorporated labelled amino-acids into the TCA-insoluble fraction, the individual regions designated as 1, 2, and so on in Fig. 2*a*, *b* were separated at 0°–4° C and then assayed for template activity. The activity (Table 2) was localized in regions 1 and 4 of the total RNA and in regions 1 and 2 in the saline-soluble RNA (that is, hRNA and 13S RNA, Fig. 2*a*,*b*). The other fractions—regions 2, 3 and 5 of total RNA and region 3 from saline-soluble RNA (22S, 17S and 4S RNA, Fig. 2*a*,*b*)—did not show activity. The DNA–RNA complex (Fig. 2*c*), which is from the 13S region of total RNA[1–3], had the highest template activity (Table 2). These results on template activity of *Euglena* RNA agree with the $^{32}P_i$-labelling experiments reported previously[17,18]. Experiments on the template activity of hRNA, which does not contain any DNA or protein[1], will be considered in detail elsewhere.

Other workers using a cell-free system detected template activity in preparations of ribosomal RNA from *Euglena*[19]. The RNAs of these preparations[19], however, were not completely resolved because, for example, only a single rRNA was reported from the cytoplasm of *Euglena*. It is therefore difficult to compare these earlier results[19] with the present findings. Regions 2 and 3 in Fig. 2*a* are ribosomal RNA[15,17] and these regions do not have any template activity (Table 2).

Effects of Drugs and Nucleases

DNA in the presence of certain drugs, for example streptomycin, can initiate amino-acid incorporation in some systems[12,13]. The effect of drugs on the translation of the complex was therefore checked. Actinomycin D did not affect the activity as expected (Table 3). Cycloheximide, which is inhibitory to eukaryotic cell-free systems[20], also did not affect the activity. By contrast, both puromycin and streptomycin strongly inhibited the activity. Further, none of the drugs used (Table 3) either initiated or enhanced the activity of the complex,

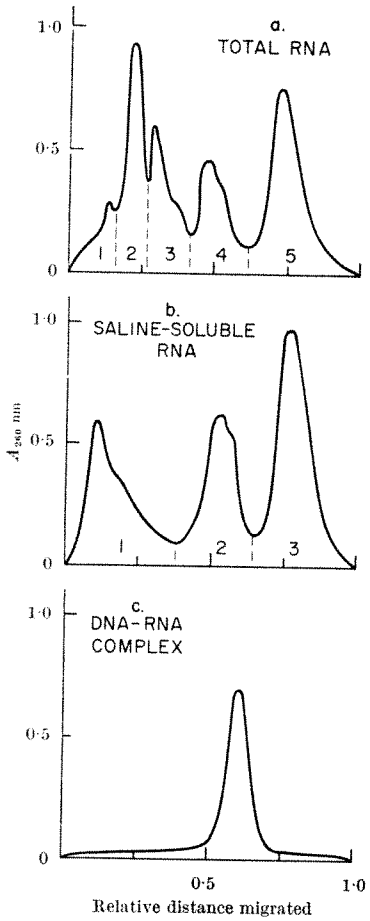

Fig. 2. Electrophoretic pattern of the total RNA (*a*), the saline-soluble RNA (*b*) and the DNA–RNA complex (*c*) from strain SM–L1 *Euglena*. About 4·0 mg of total RNA was electrophoresed on forty polyacrylamide gels[17] (100 μg per gel); each gel was carefully marked and cut as shown by the dotted lines into five regions (*a*); the corresponding pieces from all forty gels were pooled and the RNA was eluted in 100 ml. of 5 mM Tris–HCl (*p*H 7·4) and precipitated with chilled ethanol; the RNA precipitate was dried with nitrogen gas and dissolved in 5 mM Tris-HCl (*p*H 7·4) at a final concentration of 2 mg/ml. Regions 1 to 5 represent the hRNA, 22S, 17S, 13S and 4S RNAs, respectively, of *Euglena* total RNA[1,17]. The same technique was used to separate the saline-soluble RNA into three fractions (*b*). Regions 1 to 3 represent the hRNA, 13S and 4S RNAs respectively[1].

a finding which excluded the possibility of this activity being the type obtained with DNA[12,13].

As judged by electrophoretic patterns on polyacrylamide gels, the DNA–RNA complex is resistant to the action of ribonuclease and its absorbance increases on treatment with deoxyribonuclease[1]. Also, ribonuclease was without effect on the translation of the complex (Table 4). This resistance to ribonuclease is probably due to the structural assembly of the complex, but the complex lost more than 60 per cent of its activity on treatment with deoxyribonuclease (Table 4). This result indicates that a structural alteration in the complex, as reflected in hyperchromicity, leads to biological inactivation. When ribonuclease was added directly to the cell-free system, the complex showed very low activity as expected[22].

Table 2. TEMPLATE ACTIVITIES OF THE INDIVIDUAL RNA REGIONS OF FIG. 2

RNA	Region	c.p.m./mg nucleic acid
Total RNA (Fig. 2*a*)	1	4×10^4
	2	Negligible
	3	Negligible
	4	8×10^4
	5	Negligible
Saline-soluble RNA (Fig. 2*b*)	1	4×10^4
	2	$1{\cdot}2 \times 10^5$
	3	Negligible
DNA–RNA complex (Fig. 2*c*)		$1{\cdot}3 \times 10^6$

Individual regions from total RNA (1 to 5) and from saline-soluble RNA (1 to 3) were obtained as described in Fig. 2. These RNAs and also the DNA–RNA complex which has only one peak (Fig. 2*c*) were assayed for template activity as described in Table 1. The term "negligible" means that the c.p.m. were less than twice the c.p.m. of the 0·05 ml. blank.

Table 3. EFFECTS OF DRUGS ON PROTEIN SYNTHESIZING ACTIVITY OF THE DNA–RNA COMPLEX

Drug added	c.p.m./mg nucleic acid
None	$1{\cdot}30 \times 10^6$
Actinomycin D	$1{\cdot}25 \times 10^6$
Cycloheximide	$1{\cdot}31 \times 10^6$
Streptomycin	$5{\cdot}20 \times 10^5$
Puromycin	$3{\cdot}10 \times 10^4$

Drugs were added (20 μg/0·05 ml. reaction mixture) at zero time. Correction has been made for the quenching effect of actinomycin D. Other details were as in Table 1.

Table 4. EFFECT OF NUCLEASES ON PROTEIN-SYNTHESIZING ACTIVITY OF THE DNA–RNA COMPLEX

Treatment	c.p.m./mg nucleic acid
None	$1{\cdot}40 \times 10^6$
Ribonuclease	$1{\cdot}35 \times 10^6$
Deoxyribonuclease	$0{\cdot}52 \times 10^6$

The complex was treated with Worthington bovine–pancreatic deoxyribonuclease (ribonuclease-free) and Worthington bovine–pancreatic ribonuclease (deoxyribonuclease-free) as described[1]. After 20 min incubation at 2°–4° C, the reaction was stopped by adding 0·01 ml. of diethyl pyrocarbonate[21] (K & K laboratories) to each 0·2 ml. of reaction mixture. The mixture was treated with chilled ethanol. The precipitate thus obtained was dried with nitrogen gas, dissolved in 5 mM Tris buffer[1], and assayed as in Table 1.

DNA–RNA Complex from *Astasia* and Various *Euglena*

Assays for protein-synthesizing activity (Table 5) were carried out using the DNA–RNA complex isolated[1] from two wild-type strains of *Euglena* (both grown in the dark as well as in the light) and also from another flagellate, *A. longa*, which is naturally chloroplast-free. The activity of the complex was about the same in all cases ($0{\cdot}9 \times 10^6$–$1{\cdot}2 \times 10^6$ c.p.m./mg nucleic acid), indicating that the activity is not strain specific or dependent on the presence of chloroplasts.

Table 5. TEMPLATE ACTIVITY OF THE DNA–RNA COMPLEX ISOLATED FROM WILD-TYPE *Euglena* AND FROM *A. longa*

Strain	c.p.m./mg nucleic acid
Euglena bacillaris*	$1{\cdot}0 \times 10^6$
Euglena Z*	$1{\cdot}2 \times 10^6$
Euglena bacillaris†	$1{\cdot}1 \times 10^6$
Euglena Z†	$1{\cdot}2 \times 10^6$
*Astasia longa**	$0{\cdot}9 \times 10^6$

* Grown in the dark with acetate as carbon source.
† Grown in the light without acetate. Details were as given in Table 1.

Saline extraction offers a good method for separating tRNA and those species of RNA (both hRNA and the DNA–RNA complex) which have template activity from the rest of the RNAs (Fig. 2, Tables 1, 2). DNA–RNA complexes can then be isolated from the saline-soluble RNA, and such complexes have comparable template activity in all cases (Tables 1, 5). This method is applicable to *Euglena* cells, whether or not they contain chloroplasts, as well as to another flagellate, *A. longa*, which lacks chloroplasts (Tables 1, 2, 5). Similar results on the preferential extraction of template RNA with saline were reported in the case of rabbit globin messenger RNA[23]. Our results clearly show that the DNA–RNA complex isolated from various *Euglena* strains and from *Astasia* was translated very efficiently in a cell-free protein-synthesizing system. The activity of the complex was about 50 per cent of that of the highly active TYMV RNA and, further, was maximal in salt concentrations which were optimal for the TYMV RNA. The results with deoxyribonuclease indicated that translation of the complex is affected by structural alterations. In recent experiments, the bacterial message for β-galactosidase was transcribed and translated *in vitro*[24]. In the present work, it seems that we have isolated eukaryotic DNA in the

process of transcription *in vivo* and have translated the resultant RNA *in vitro*. Experiments are under way to elucidate the exact mechanism of translation of the complex on the ribosomes.

We thank Dr John M. Clark, jun., for his assistance in these experiments. This investigation was supported by a grant from the US National Institute of Child Health and Human Development.

Mechanism of Inhibitory Action of Histones on DNA Template Activity *in vitro*

by
YU. V. KOSLOV
G. P. GEORGIEV
Institute of Molecular Biology,
USSR Academy of Sciences,
Moscow

If RNA is synthesized on the chromatin deoxyribonucleoprotein (DNP) template, the chains formed are four to five times shorter than in RNA synthesized on a DNA template. This correlates with the decrease of the period of elongation. After the removal of histone FI from DNP the RNA chains synthesized are as long as or longer than those formed on free DNA. Histone FI seems to prevent the movement of RNA polymerase along the DNA.

It is well known that complete chromatin deoxyribonucleoprotein obtained at low ionic strength (DNP_0) is a poor template compared with free DNA, usually making about ten times less RNA[1-4]. What is the mechanism of this decrease and which steps of the RNA polymerase reaction are inhibited by proteins combined with DNA? The RNA polymerase reaction has several stages: binding of the enzyme with the template, initiation of RNA synthesis, chain elongation and termination[5-6].

To find out whether histones interfere in this process we have studied the synthesis of DNA on calf thymus DNA and DNP templates, using RNA polymerase isolated from *E. coli*, UTP randomly labelled with ^{14}C, and ATP or GTP labelled with ^{32}P in the γ-position. The incorporation of ^{14}C gave information about the total RNA synthesis, and that of ^{32}P told us the number of chains initiated[7]. In some experiments rifampicin was used to inhibit the reinitiation of RNA chains[8,9], for even at low ionic strength there is some reinitiation with GTP[10].

In this article S is taken as full RNA synthesis in moles of nucleotides related to 1 mole of DNA nucleotides. It was calculated by multiplying the amount of ^{14}C-UMP incorporated by 3·4 as calf DNA contains about 29 per cent of dAMP. n is the total number of initiated chains (in moles) also related to 1 mole of DNA nucleotides. It is the sum of ^{32}P-ATP and ^{32}P-GTP incorporation. The value of n gives information about enzyme binding and initiation. l is average chain length of nucleotides, so that $l = S/n$. It depends on the rate of elongation (V) and time of elongation (t)—$V = \Delta l/\Delta t$. It can be determined more precisely using rifampicin. V usually decreases with the elongation of the RNA chain[10].

As well as these parameters one can also determine t', the time of initiation, and V', the rate of initiation ($V' = \Delta n/\Delta t$).

DNA Synthesis on DNA and DNP Templates

Table 1 shows the principal parameters of RNA synthesis on different templates. As Maitra and Hurwitz[7] have shown, RNA chains synthesized *in vitro* are initiated with pppA or pppG. But a difference between the initiation kinetics of ATP and GTP was found: with ATP, initiation is completed during the first 10 min, whereas initiation with GTP continues for a long time. It depends on the reinitiation of the chains, beginning with GTP. Additional factors (similar to σ) may be responsible for the difference between initiation with ATP and GTP.

Table 1. PRINCIPAL PARAMETERS OF RNA SYNTHESIS ON DIFFERENT TEMPLATES

Template	S after 33 (34) min: Without rifampicin	S after 33 (34) min: With rifampicin	$n \times 10^6$: After 3 (4) min	$n \times 10^6$: After 33 (34) min	l* After 33–34 min	V For 0–8 (9) min interval	t (min)
DNA	0·50	0·79	300	494	1,700	130	>30
DNP_0	0·023	0·072	58	173	400	140	≦3
$DNP_{0.6}$	0·32	0·52	137	450	2,300	144	>30
DNPur	0·040	0·14	86	164	470	—	~5–6

* Values of l are taken from experiments when rifampicin was added. In general they are very close to values obtained without rifampicin.

The value for V, determined using rifampicin, is about 130 nucleotides/min (for the first 8 min). It should be noted that samples were incubated at 25° C which would decrease the rate of RNA synthesis (Fig. 1).

The value of n is 300 in experimental conditions, which means that one RNA polymerase molecule combines with a DNA piece of about 1×10^6 daltons. This figure is not far from those obtained by Pettijohn and Kamiya[11] using DNA saturated with enzyme.

RNA synthesis on the DNP_0 template (Fig. 2) is about ten times slower than on free DNA. This depends first on the sharp decrease (four to five times) of l. This may be a result of the decrease of t or V. The use of rifampicin confirmed the first suggestion. After the addition of rifampicin no further increase of l was observed. The value of t is not more than 3 min. It is impossible to determine V precisely from such experiments, but if we assume t to be 3 min and l to be 400 (Table 1), then V is at least 140 nucleotides/min. Thus the rate of elongation with the DNP_0 template is of the same order of that with DNA. Thus RNA is synthesized on DNP_0 and DNA at a similar rate, but it is stopped earlier on DNP_0 because of obstacles to the movement of RNA polymerase.

The value of n is also decreased on DNP_0 (two to three times after 30 min of incubation; after a short incubation this difference is much greater). This is probably a result of decrease of V', whereas t' increases. Such initiation kinetics may simply depend on the lower availability of the template for the enzyme, for the DNP is precipitated in the conditions of the RNA polymerase reaction.

In general the decrease in the rate of binding and initiation influences the total RNA synthesis less than the early stopping of chain elongation.

RNA Synthesis on DNP extracted by Sodium Chloride

The removal of histone F1 (according to Johns's classification of histones[17]) by 0·6 M NaCl extraction leads to a sharp increase of DNP template activity. On the other hand, RNA synthesized on such DNP ($DNP_{0\cdot6}$) could not be distinguished from RNA synthesized on DNA by its hybridization properties[4,12]. Although some non-histone proteins are also extracted from chromatin by 0·6 M NaCl, the reconstitution experiments indicated that of the extracted proteins only histone F1 inhibits RNA synthesis[14].

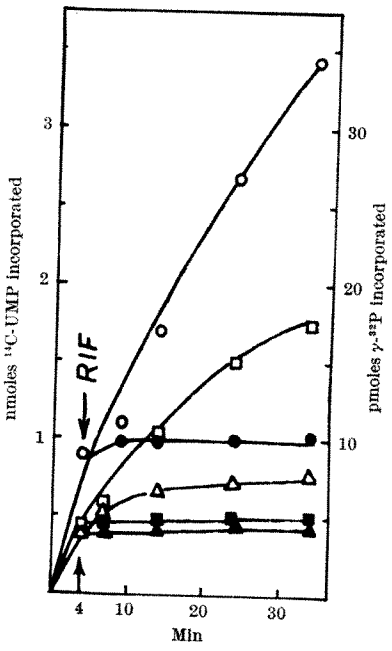

Fig. 2. RNA synthesis on the DNP_0 template with and without rifampicin. Conditions were the same as for Fig. 1 except that DNP_0 (containing 50 μg of DNA) was added instead of DNA, and the time of preincubation lasted 4 min before the addition of rifampicin. Symbols are as in Fig. 1.

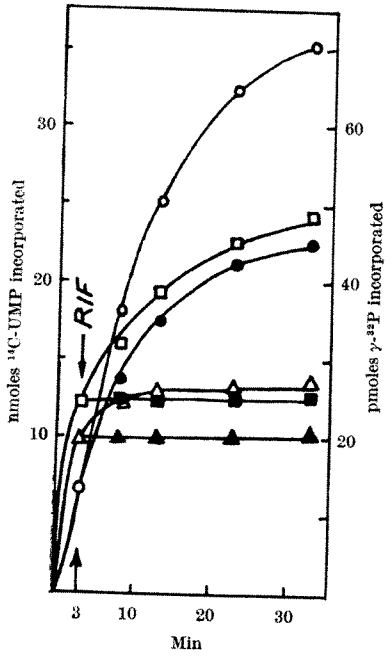

Fig. 1. RNA synthesis on the DNA template with or without rifampicin. Each tube contained in 0·5 ml.: 20 μmoles of Tris-HCl (pH 8·1); 2 μmoles of $MgCl_2$; 0·5 μmoles of $MnCl_2$; 0·2 μmoles each of ^{14}C-UTP, specific activity 200 counts/nmole, γ-^{32}P-ATP and γ-^{32}P-GTP-specific activity 100–200 counts/pmole; 5·4 μmoles of mercaptoethanol; 50 μg of DNA and 22 U of RNA polymerase (1 U gives rise to the incorporation of 1 nmole of UMP in 10 min at 25° C). RNA polymerase was isolated from *E. coli* by the method of Burgess[15] with slight modifications—it contained σ factor. γ-^{32}P-ATP and GTP were synthesized according to Penefsky *et al.*[16]. Samples were incubated at 25° C. Rifampicin was added to half of the sample 3 min after the start of incubation. The reaction was stopped by the addition of 1·5 ml. of 0·5 per cent sodium dodecyl sulphate in 0·01 M pyrophosphate (pH 8). RNA was deproteinized by phenol and chloroform, purified by gel filtration through 'Sephadex G-25', washed with 5 per cent trichloroacetic acid on a 'Millipore' filter and counted in a Geiger counter. ^{32}P and ^{14}C were separated by using a corresponding filter. Samples 1 (○), 3 (△) and 5 (□) were incubated without rifampicin; rifampicin was added after 3 min of incubation (5 μg/0·5 ml.) to samples 2 (●), 4 (▲) and 6 (■). 1 and 2 represent ^{14}C-UMP incorporation; 3 and 4 represent ^{32}P-ATP incorporation, and 5 and 6 represent γ-^{32}P-GTP incorporation.

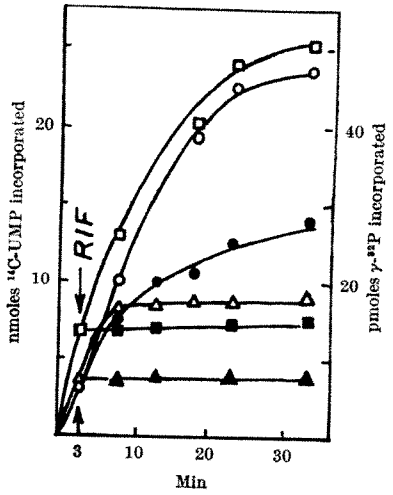

Fig. 3. RNA synthesis on the $DNP_{0\cdot6}$ template with and without rifampicin. Conditions were the same as for Fig. 1, except that $DNP_{0\cdot6}$ containing 50 μg of DNA was added instead of DNA. Symbols are as in Fig. 1.

Fig. 3 shows that the limitation of RNA elongation typical of DNP_0 is absent in the case of $DNP_{0\cdot6}$. The RNA polymerase moves along the $DNP_{0\cdot6}$ strand at the same rate and for the same time as in the case of free DNA. $DNP_{0\cdot6}$ is insoluble in the reaction medium, so that aggregation cannot explain the difference of transcription from DNP_0 and $DNP_{0\cdot6}$.

The removal of histone F1 must also remove the obstacles to the movement of RNA polymerase along DNA. Other histones (F2a1, F2a2, F2b and F3) do not influence this process.

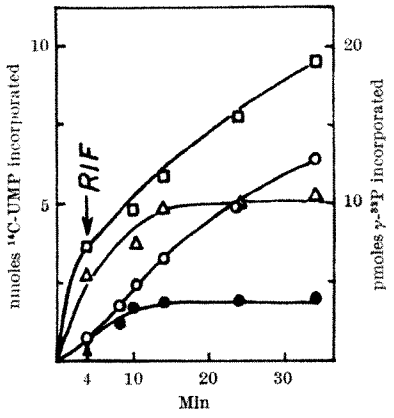

Fig. 4. RNA synthesis on the DNP_{ur} template with and without rifampicin. Conditions were the same as in Fig. 1 except that the DNP_{ur} (contains 50 μg of DNA) was added instead of DNA and the time of preincubation lasted 4 min before addition of rifampicin. Symbols are as in Fig. 1.

Other findings include a smaller value of n compared with those typical of DNA, especially after a short incubation. After 30 min of incubation this difference is negligible, perhaps because of the lower availability of aggregated template for the RNA polymerase, with a resulting decrease in V'.

RNA Synthesis on DNP treated by Urea

Does the early stopping of RNA polymerase progression depend on interference with histone F1 itself or on the DNP superstructure for which histone F1 is responsible? To resolve this question we have investigated the template properties of DNP_0 treated by 4 M urea (DNP_{ur}). It had been found that DNP_{ur} contained all the proteins of the original DNP_0, including histone F1, but the superstructure was destroyed[12]. After the removal of urea by dialysis against 0·001 M Tris this superstructure was not reconstituted.

Fig. 4 and Table 1 show that in the case of DNP_{ur}, as well as DNP_0, RNA elongation stops very soon. Values of t and l are only slightly higher than for DNP_0. Thus the presence of histone F1 on the DNP strand seems to be responsible for the early stopping of enzyme movement.

Our findings indicate that the poor template activity of chromatin or DNP_0 depends first on the formation of stop-points for the movement of RNA polymerase along the template. For this reason the time of chain growth and the average length of the chains decrease four to five times. Histone F1 is probably responsible for this effect, for its removal leads to the removal of obstacles to RNA polymerase progression.

Although the relation of this phenomenon to the *in vivo* situation is not clear, *in vivo* histone F1 could also prevent the movement of the RNA polymerase.

It is interesting that bacterial repressors, in particular the lac repressor, act in a similar way. The lac repressor combines with the operator, localized between the promotor and the structural genes, and prevents the RNA polymerase from moving to the structural genes[13].

Perhaps F1 histones are localized in the proximal parts of operons near promotors, and so inhibit RNA synthesis in corresponding operons[14].

Another important conclusion from our results is that the presence of four principal histone fractions in a complex with DNA does not influence the template properties of DNA—long RNA chains are synthesized. Thus RNA polymerase does not need a "naked" DNA for its action. DNP with a high protein content (total protein to DNA ratio in $DNP_{0.6}$ is equal to 1·1) may serve as a very effective template.

We thank Dr R. Burgess for information about his new method for RNA polymerase isolation before publication, and Mrs N. N. Dobbert and Mrs T. L. Turenko for technical assistance.

A Ligand Exclusion Theory of Allosteric Effects

by

HARVEY F. FISHER
RONALD E. GATES
DALLAS G. CROSS

Veterans Administration Hospital,
4801 Linwood Boulevard,
Kansas City, Missouri 64128

Cooperative and allosteric effects are explained by a theory involving not conformational changes but steric exclusion through interactions between multifunctional ligands which bind to common and topologically distinct subsites.

An increasing amount of attention has recently been focused on a group of enzymatic phenomena generally categorized as "allosteric" or "cooperative" effects. These phenomena may include: a sigmoid dependence of reaction velocity on substrate or cofactor concentration; activation by compounds structurally unrelated to reactants or products; effects of ligands on binding at sites topologically distinct from their own; and the obligatory sequential binding of substrates. Elegant and ingenious theories[1–3] have been developed to provide a comprehensive explanation for this diverse group of effects. These theories and the evidence supporting them

have been reviewed by Koshland[4], who has devised a nomenclature that is most useful for discussions of such enzyme-regulatory effects. In spite of important differences in these theories, their proponents are in general agreement with Stadtman[5], who has concluded that "one is led to the inescapable conclusion that the binding of the inhibitor to the allosteric site results in a change in the conformational state of the protein to a form with lowered affinity for the substrate at the catalytic site". We present here an alternative class of mechanisms which demonstrate that the conclusion just cited is by no means inescapable.

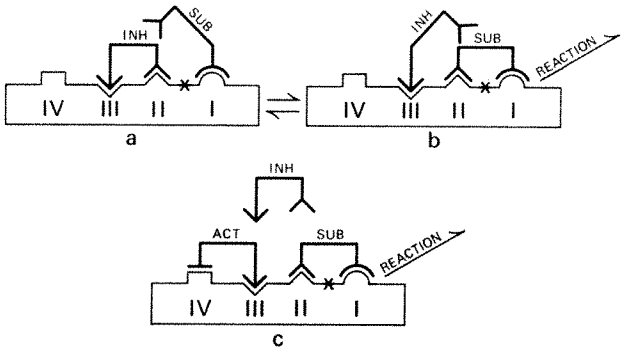

Fig. 1.

Fig. 1 is a schematic representation of an enzyme surface possessing four subsites, each capable of binding a functional group on a ligand. Also shown in Fig. 1 are three different ligand species, each possessing two functional groups which are capable of binding independently to a subsite. Assume a general case in which at any given moment each bidentate ligand may be bound to the enzyme at either one or two subsites; further assume that catalysis can occur only when the substrate ligand (Sub.) is bound to both subsites I and II. In the absence of activator (Act.), both inhibitor (Inh.) and substrate may bind to the enzyme simultaneously, as shown in Fig. 1*a* and *b*, but at a given moment only one ligand can be bound in a bidentate manner, for subsite II is required for the bidentate binding of either ligand. If, as assumed in Fig. 1, both ligands bind much less tightly to subsite II than to the other two subsites (I and III) a non-competitive inhibition will be observed because the competition for subsite II by the substrate and inhibitor ligands is through an isomerization step which is not a concentration dependent one[6]. The binding of an activator ligand at subsites III and IV relieves the inhibition and results in the complex depicted in Fig. 1c. The binding of an activator ligand in a monodentate manner to subsite III would also decrease the inhibition. It is obvious that an enzyme system exhibiting such behaviour would certainly be described as allosteric. It should be noted that it is by no means necessary that the ligands involved have recognizably similar structures; they need only possess single functional groups capable of binding in some manner to the same subsite. Some simple variations of the scheme just described in Fig. 1 exhibit other aspects of cooperative or allosteric interaction.

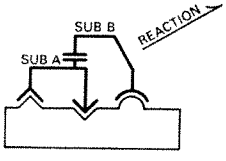

Fig. 2.

Fig. 2 portrays the active complex of a two-substrate reaction in which substrate A contains one of the two subsites required for the productive binding of the second substrate (B). An obligatory sequential ordered reaction must result and the two substrates will now each enhance the binding of the other in a typical cooperative interaction. Such behaviour frequently has been taken as evidence of a substrate-induced conformational change (ref. 4, pp. 381 and 395). If the two substrates are identical, the rate equation is

$$v/V = \frac{\alpha s^2}{1+\beta s+\alpha s^2} \qquad (1)$$

This equation is a special case of a more general one discussed by Reiner[7] and permits a sigmoidal dependence of velocity on substrate concentration.

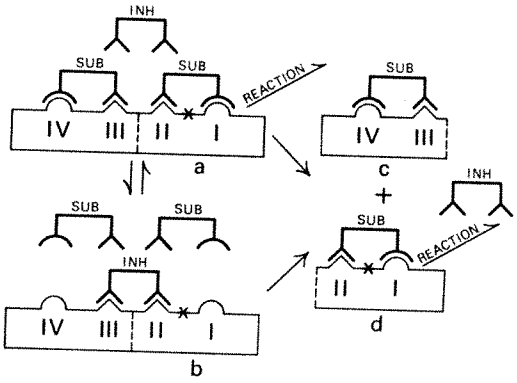

Fig. 3.

Now consider the system shown in Fig. 3*a* and *b*, representing an enzyme which can bind an identical substrate in two different and non-interacting modes (I–II and III–IV), only the former of which is productive, as indicated by the asterisk. The enzyme can also bind an inhibitor to a combination of subsites II and III, each of which also forms part of the two separate substrate binding sites. Assuming the simplest case in which all ligands are either bound in a bidentate manner to two subsites or not bound at all, the enzyme can form two different complexes: (*a*) in which the inhibitor is not bound and both substrates may be bound, and (*b*) in which the inhibitor is bound and neither substrate can be bound. The kinetic equation which results is

$$v/V = \frac{\alpha s+s^2}{(\alpha+\beta)s+s^2+\alpha\beta(1+\gamma I)} \qquad (2)$$

In the presence of a sufficient concentration of inhibitor, this system will display a sigmoid dependence of velocity on substrate concentration. In the absence of inhibitor a normal hyperbolic dependence will be seen. The maximal velocity is independent of inhibitor concentration. If the enzyme consists of two dissociable subunits as indicated by the dotted line in Fig. 3*a* and *b*, dissociation will lead to a mixture containing subunit c which is catalytically inactive but still capable of binding a substrate molecule, and subunit d which is catalytically active. The ability of either subunit to bind inhibitor will be greatly diminished. The system will now show normal hyperbolic kinetics even in the presence of inhibitor at any concentration. If the dissociated subunits differ in physical properties sufficiently to be separable, then subunit d would be found to have full catalytic activity and would exhibit normal hyperbolic kinetics even in the presence of inhibitor; and subunit c would be found to be catalytically inactive. Subunit c would then most reasonably be described as a "regulatory subunit" and d the "catalytic" subunit. It is also apparent that the location of specific subsites on dissociable subunits in cases similar to those we have

described could lead to a "normalization" of sigmoid kinetics by subunit dissociation. If the dissociation into subunits represents a reversible system, then the scheme of Fig. 3 predicts that the presence of inhibitor could favour formation of the associated form by forming a strap across the interface, and thus cause the formation of more of its own ligand binding sites. The behaviour of this scheme presents an interesting analogy to certain features of a number of multisubunit enzymes.

A significant distinction between the concepts proposed here and conformation-change theories is that we specifically assume that the occupancy of a given subsite by a ligand functional group has no effect on the micro-constants of binding of functional groups to any other subsite. On the other hand, such occupancy of a subsite can effect an overall ligand binding constant (generally the product of two or more micro-constants). Thus the ability of multifunctional ligands to connect a group of topologically distinct subsites can lead to a variety of effects commonly described as allosteric.

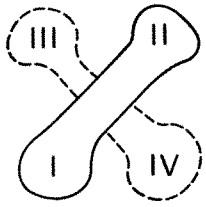

Fig. 4.

A somewhat more general model, freed even of the simple assumption of ligand sharing of common subsites, is quite capable of explaining the same range of allosteric and cooperative effects. Fig. 4 represents an enzyme with four subsites, no two of which are capable of binding the same functional group, which are arranged on an enzyme surface so as to constitute the corners of a rough square. If one bidentate ligand, possessing the proper pair of functional groups and the required inter-group distance, can bind to the I–II pair of subsites, and a totally different ligand can bind to the III–IV pair; then the binding of either one of the two ligands may exclude the binding of the other by simple steric hindrance even though the two do not have a single binding subsite in common and have absolutely no structural resemblance to each other. Such simple steric exclusion can result in cooperative and allosteric effects similar to those produced by common subsite occupancy. The combination of these two mechanisms can result in even more complex behaviour.

It is interesting to note that the definition of allosterism[8] arose from the apparent inadequacy of an overlapping site theory proposed by Changeux[9] to explain the effects of L-isoleucine on L-threonine deaminase activity and abandoned by him in favour of a separate but interacting site model. The kinetic effects described by Changeux are easily explained by the concepts proposed here. The difference in viewpoint involves primarily the distinction between subsites and ligand binding sites; the ligand binding site consists of the sum of its specific subsites and all of the surrounding space occupied by the bound ligand.

Conformational change theory explains the effect of the binding of one ligand on the binding of another as a result of ligand–enzyme–ligand connectivity whereas ligand exclusion theory proposes that these same effects are caused by direct ligand–ligand interactions; in this case the connectivity is afforded either by common binding subsite utilization or by simple steric exclusion. Both theories predict identical kinetic consequences and therefore only direct physical evidence of protein conformational changes or ligand–ligand interactions causally connected with ligand binding can distinguish between the two mechanisms.

Recent spectroscopic studies in our laboratory have permitted the resolution of multiple binding of several ligands to glutamate dehydrogenase[10]. The results provide direct evidence of a number of situations quite similar to combinations of the interactions postulated above, and have led us to consider the applicability of such ligand exclusion as a possible explanation of similar effects in other enzyme systems. Our purpose here is not to attempt to assess the relative weights of evidence supporting the ligand exclusion theory and those theories which explain identical effects by assuming changes in tertiary conformation, but rather to suggest an alternative general mechanism which should be given careful consideration in any specific case in which conformational changes have not been actually observed and shown to be causally connected to the kinetic behaviour.

We thank Drs William Wallace Cleland and Paul Srere for helpful discussions. This work has been supported in part by grants from the US National Science Foundation and the US National Institutes of Health.

Palaeohistory of the Spruce in Switzerland

by
VERA MARKGRAF
Systematisch-Geobotanisches Institut, Universität Bern, 3013 Bern, Switzerland

Pollen and carbon dating suggest that the Post-Glacial spread of the spruce (*Picea*) in Switzerland has been influenced by human activity. This is different from the situation in the eastern Alps.

BASED on a preliminary comparison of dated sections of sediments from different localities (Fig. 1), I should like to suggest that human activity was responsible for the spread of the spruce (*Picea abies* H. Karst) in the Swiss forests during Post-Glacial times. The comparison was made possible by numerous carbon-14 dating and pollen analyses of soil profiles (Fig. 2), on the assumption that changes in vegetation are reflected in the relative pollen composition of sediment horizons[1].

In Switzerland the oldest traces of *Picea* pollen, which mark the immigration of this tree, generally reach back to Atlantic times[2–5]—7,000 to 6,000 BP*, as in central Europe[6]. Only east of the upper Inn River did *Picea* arrive and spread as early as Pre-Boreal and Boreal times, about 9,000 BP (unpublished results of M. Welten)—as in the

* Dates are given in conventional carbon-14 years before AD 1950 called BP, before present) as calculated from the measured activities and use of adopted standards without use of calibration curves[6,7].

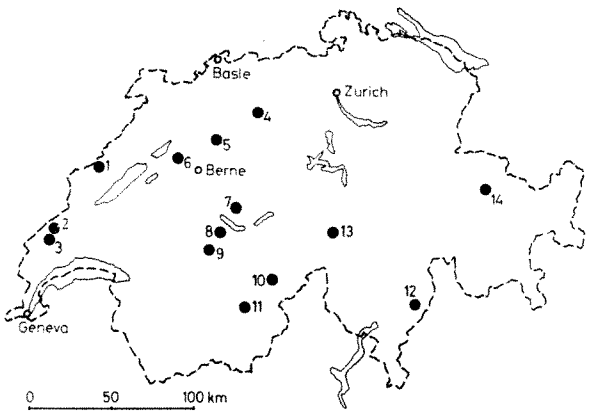

Fig. 1. Map of Switzerland showing localities where pollen was investigated (see profiles in Fig. 2). (1) Le Cachot, altitude 1,050 m, near La Brévine, in central Jura (canton Neuchâtel) (F. Matthey, in preparation); (2) Les Cruilles, 1,035 m, near Lac de Joux, in South-West Jura (canton Vaud)[3]; (3) Le Marais des Amburnex, 1,300 m, near Col du Malchairuz, in South-West Jura (canton Vaud)[3]; (4) Fätzholz, 476 m, near Murgenthal, Mittelland (canton Aargau)[21]; (5) Burgmoos, 460 m, near Seeberg, Mittelland (canton Berne)[2]; (6) Lobsigensee, 514 m, near Aarberg, Mittelland (canton Berne)[22]; (7) Hängstli, 1,260 m, valley of Eriz, near Thun, N limestone Alps (canton Berne) (K. Heeb, in preparation); (8) Egelsee, 1,000 m, Simmenthal, N High Calcareous Alps (canton Berne)[2]; (9) Sewlenboden, 2,120 m, near Lenk, Simmenthal, N High Calcareous Alps (canton Berne)[2]; (10) Aletschwald, 2,010 m, near Brig, central Alps (canton Valais) (M. Welten, in preparation); (11) Bonigersee (or Böhnigsee), 2,095 m, near Visp, central Alps (canton Valais)[4]; (12) Pian di Signano, 1,540 m, Misox valley, S Alps (canton Ticino)[5]; (13) Göscheneralp, profile Berg, 1,940 m, central Alps (canton Uri)[11]; (14) Faninpass, 2,220 m, near Chur, Swiss E Alps (canton Graubünden) (P. Wegmüller, in preparation).

Eastern Alps[9–11] (Fig. 2, locality 15), where *Picea* became established immediately when climate improved at the beginning of the Post-Glacial. West of the upper Inn River, however, spruce seems to have spread no farther for several thousand years after its arrival (unpublished results of P. Wegmüller), a pattern which has also been reported for Germany[6].

It was previously thought that the amount of spruce pollen deposited increased in the Sub-Boreal period[2–5], but radiocarbon dates[12] suggest that expansion was not simultaneous in different places. Even pairs of localities less than 20 km apart at comparable altitudes differ in the date of expansion by about 2,000 yr: for example, Les Cruilles–Le Marais des Amburnex (Fig. 2, profiles 2 and 3) and Aletschwald–Bonigersee (Fig. 2, profiles 10 and 11). Dates of expansion for *Picea* vary from 7,000 BP (Fig. 2, profile 14) to 1,000 BP (Fig. 2, profiles 5 and 6) with a mode at about 5,000 BP (Fig. 2, profiles 2, 7, 8, 9, 11 and 13).

To interpret the problem of *Picea* it is necessary to explain the interruption of its development west of the upper Inn River and the different dates of expansion at different localities. The cause of these effects must have been local and strong enough to have induced the changes in vegetation which made spread possible. Climatic changes alone cannot have been responsible, particularly in view of Frenzel's observations[13] that a "climax" forest has its own climate, as a result of centuries of undisturbed development. Such a forest is not easily altered, even by minor environmental changes. In any case, recent investigations of the Atlantic and Sub-Boreal climate have shown fluctuations to have been of minor importance[13]: for example, a short cold spell (*Piora Kaltphase* of Zoller[5]) occurred about 5,000 BP and has previously only been detected in sections near the alpine timber line[14,15]. The change to a continental climate during the Sub-Boreal period was too slow and weak to explain the sudden expansion of *Picea*.

Signs of Human Influence

Another solution was suggested by the changes in vegetation indicated in the profiles contemporaneous with the increase in *Picea* pollen. These changes can be summarized as follows. First, there was a general decrease of pollen of *Abies alba* (fir), *Pinus cembra* ("Arve") and the so-called mixed oak forest (*Ulmus*, *Tilia* and *Quercus* spp.) with a simultaneous increase of herb pollen, chiefly Gramineae. Soon after this the dominant species were shrubs and heliophilous trees (*Corylus*, *Alnus*—also *Alnus viridis*—or *Betula*), and then trees which required shade. Iversen thought that this succession indicated re-afforestation[16]. In two places (Fig. 2, profiles 11 and 12) associated charcoal horizons were found, indicating that forest had

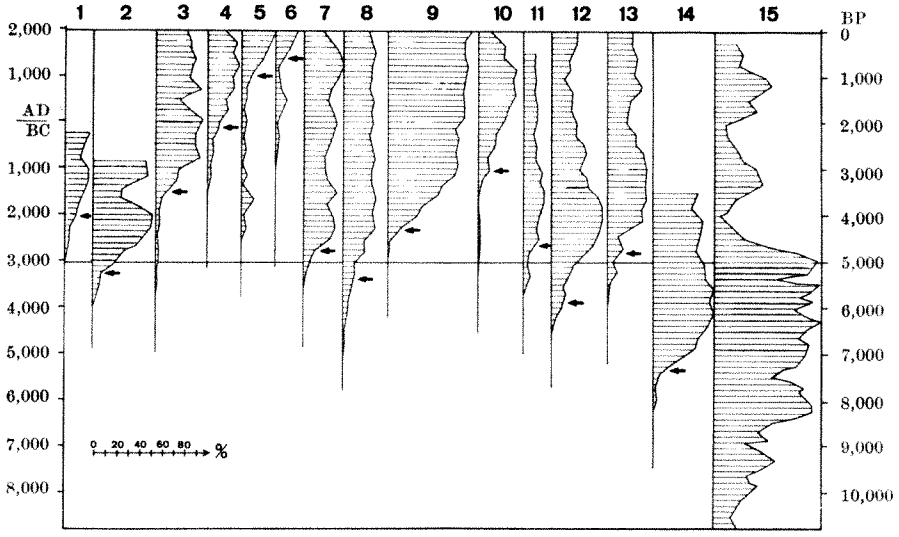

Fig. 2. Pollen profiles at localities numbered in Fig. 1. No. 15, not marked on Fig. 1, is in Austria: Lengholz I, 570 m, in Drau valley, Carinthia, South-East Alps[10]. The abscissae show the amount of *Picea abies* pollen relative to total pollen in each horizon. The ordinates give time in ^{14}C years: to the right as BP (before present), to the left their equivalent in conventional ^{14}C years AD/BC. Profiles 4 and 9 were not directly radiocarbon dated, but pollen analysis data were compared with ^{14}C dated profiles. The arrows mark the onset of the spread of *Picea* at the point where *Picea* pollen exceeds 10 per cent of all pollen.

been cleared[2,5]. Second, there was a decline of *Ulmus* (elm) in the mixed oak forest pollen, indicating a final change in the composition of that forest type. Third, there were the first traces of cereal pollen, which showed that agriculture was being practised, and there was the invasion of weeds such as *Plantago lanceolata*.

These three changes are all related to human activity[16–18], although the importance of this influence has been questioned[13,19]. The charcoal horizons at the upper limit of the forest confirm the great impact of man on nature at the onset of the Neolithic. Because these changes were contemporaneous with the dates of expansion of *Picea* I think that the spread of this species was also due to human influence.

Local Activity

Human activity is likely to have been local for two reasons. First, Neolithic people almost certainly immigrated from the Mediterranean region, bringing agriculture with them. It is unlikely that their clearing activity would have been simultaneous throughout Switzerland (that is, one should find their traces earlier in southern than in northern localities). Second, the different suitability of the localities for cultivation could be accounted for by the different times of expansion; the places estimated to have been of low agricultural productivity were cleared distinctly later than the more productive places (Fig. 2, localities 10 and 11).

Human activity is also likely to have been a strong influence. Not only the more or less continuous clearing of the forests by fire, but especially subsequent grazing by cattle, destroyed the previous vegetation and made natural re-afforestation impossible (private communication from H. Oberli). Thus species which were less adaptable to continuous disturbances would not have survived, and *Picea*, which is less sensitive, came to be dominant.

I therefore consider that the conditions for the spread of the spruce in the forests of Switzerland were different from those described for the eastern Alps, where *Picea* arrived earlier than any other Post-Glacial tree. The interruption of expansion west of the upper Inn River was due to competition from *Abies alba*[21], *Pinus cembra* and *Larix decidua*, which had already become established after immigrating from the south into Switzerland across the Alpine passes.

In summary, large scale expansion of *Picea* was only possible in Switzerland after man had destroyed the previous natural composition of the forests. Such great changes in vegetation were not necessary in pre-agricultural times—until about 5,000 BP[20]. The subsequent rapid development of *Picea* was also supported by climate, even if the climatic fluctuations were minor. Other factors such as soil development and plant diseases certainly contributed in some degree to the spread of *Picea*, but none were effective enough to have started the process by themselves.

I thank M. Welten for helpful discussions. This work was supported by the Schweizerischer Nationalfonds.

Trace element analyses of flint show statistically valid differences between products of major British and European Neolithic flint mines.

STONE axe-heads for tree felling and clearing the land were part of the staple equipment of the early farmers. In the Neolithic and Early Bronze ages outcrops of suitable hard rocks and easily accessible flint bands in the chalk regions were exploited on a large scale for the manufacture of axe-heads. Such major axe factories are relatively rare; there are perhaps fifteen–thirty sites in the British Isles and it seems likely that many of the axe-heads found elsewhere are their products.

Petrological analysis by thin section has enabled the locality of origin of axes made from hard rock to be identified and, incidentally, has demonstrated their trans-

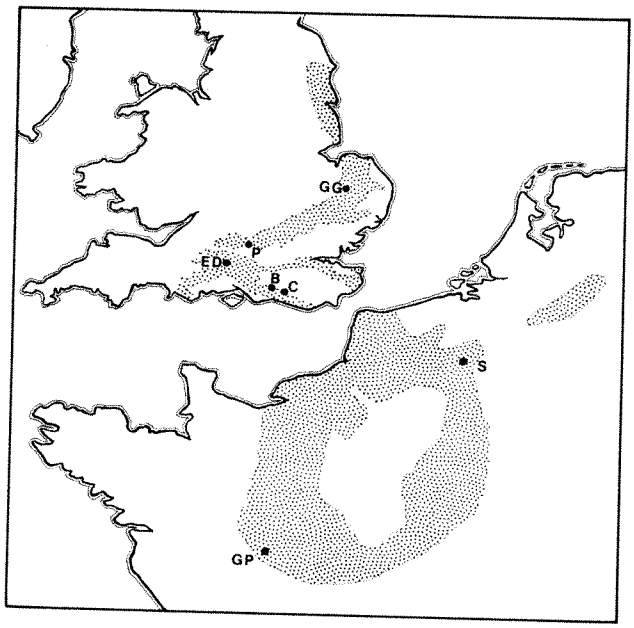

Fig. 1. Distribution of the flint mines and axe factories whose products have been analysed. Shading indicates outcrop of the Cretaceous Chalk. The sites are ED, Easton Down; GG, Grimes Graves; GP, Grand Pressigny; B, Black Patch; C, Cissbury; P, Peppard; S, Spiennes.

port over long distances[1]. Lake District axes are found in datable prehistoric contexts as far afield as Wiltshire, and specimens of Cornish origin occur in East Anglia. Such are isolated instances. The majority of the tools were used in areas with easier access to the factory sites although large scale distribution of the Langdale factory extends as far as the West Riding of Yorkshire.

In the Chalk regions it has not yet been possible to demonstrate such trade or transport of axe-factory products because the majority of axe-heads are made of flint whose place of origin cannot be identified petrologically. Certain geographically restricted varieties of flint are said to have a characteristic appearance, but no satisfactory objective method has yet been found of demonstrating these differences[2,3].

Because flint is largely composed of silica and water it was thought that analysis for trace elements might prove a satisfactory method of distinguishing flint from different localities. To check this hypothesis it was decided to analyse a restricted sample of flint from the flint seams of some of the major axe factory/flint mines in southern Britain and Continental Europe. It was recognized that flint might be similar in its trace element constitution and therefore we selected sites which were well separated. Two British sites were chosen specifically, however, because they were close together and might be expected to be indistinguishable by their trace element content. These are Cissbury and Black Patch, here taken as representative of the South Downs group of flint mines. In the analysis that follows, the results from these sites are tabulated and their localities are shown in Fig. 1.

It will be seen that on the restricted sample of twenty specimens analysed from each flint mine/axe factory, all the sites whose products are analysed can be clearly distinguished from one another, except in the instance of the two sites in the South Downs group, whose trace element composition is very similar.

Petrology of the Flints

The flint discussed here is a form of chalcedony that occurs as bands and nodules in the soft white limestone of Upper Cretaceous age called the Chalk (Fig. 1). Chalcedony is composed of micro-crystalline alpha quartz with crypto-pores filled with an aqueous solution[4]. This means that pure chalcedony consists of silica, water and the dissolved constituents of the water. If the flints found in the chalk were pure chalcedony they would probably not have a very variable trace element content.

The origin of nodular and tabular flints and cherts of the type found in chalk has long been a source of interest. There are two principal theories for their origin: (1) syn-depositional precipitation of silica gel which matures into chalcedony, and (2) post-depositional segregation of silica. With Chalk flints the second theory seems best to fit the evidence provided by mode of occurrence. The nodule or vein of flint would form, at least in part, by the replacement of calcium carbonate by silica. Growth of the flint would be outwards from a nucleus or nuclei and the replacement would be piecemeal. No cavity would be formed and most of the non-carbonate material in the chalk would be incorporated in the flint. The most common non-carbonate materials are quartz, clay minerals and heavy minerals; these occur in various proportions and they are the most likely source of the trace elements. The distribution of non-carbonate material in Chalk varies both laterally and vertically[5–8]. The lateral changes in composition are normally not rapid except where the margins of Chalk deposition are approached. Vertical variations may, however, be quite sudden and considerable which means that the flints from one horizon in one locality will not normally vary widely.

Chalk flints have a noticeable outer skin, cortex or patina, which is present both on flints freshly removed from the calcareous matrix and on well weathered flint fragments or implements. The origin of the layer is, however, different under these two circumstances. The cortex on the unweathered flint is the result of the growth of the nodule or vein, while the patina on the fragments or implements is the result of weathering and partial solution. From an analytical viewpoint both layers are undesirable and are removed before analysis.

Analytical Methods

Samples were obtained by drilling the flint specimen with a high speed, diamond impregnated, hollow core drill which gives a cylinder of material. The top of this core, comprising the weathered outer layer and the first few millimetres of unaltered flint, was removed and discarded. The cylinder of flint was cleaned in boiling aqua regia for approximately two minutes to remove any surface contamination arising from the process of sampling. The cylinders are extremely hard and dense and there is no danger of leaching out the trace elements by this procedure. One sample was boiled for several hours with no apparent change in either its appearance or chemical composition on analysis.

In preparing a finely powdered sample for analysis, difficulties arise because the flint is extremely hard. Initial experiments using a combination of steel percussion and boron carbide mortars resulted in heavy sample contamination and severe damage to the surface of the boron carbide mortar. It was found, however, that the sample could be broken up and its hardness reduced by rapid heating and quenching in water. This was done by dropping the cleaned sample into a red hot pure nickel crucible and immediately replacing the lid. Because of the expansion of small amounts of structural water the flint shattered violently. The fragments were then tipped into cold distilled water, which rendered them more friable. They were then dried at 120° C and were ground in an agate mortar to a fine powder. The sample was then ready for weighing and analytical treatment by the following methods.

The initial quantitative survey was carried out by emission spectroscopy using a technique in which the finely ground powdered flint, mixed with twice its weight of 'Specpure' graphite powder, was packed into cupped, necked, graphite electrodes and arced for 30 s at 8 A with

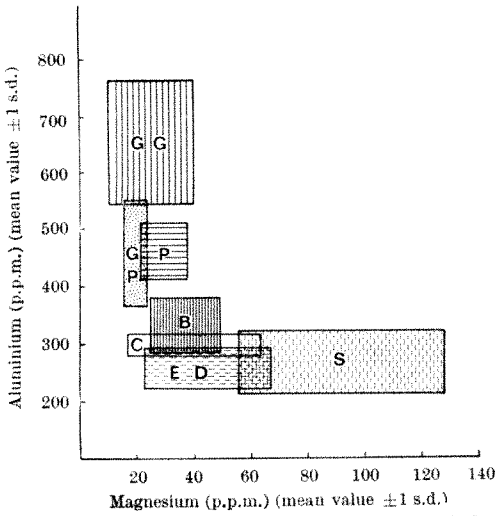

Fig. 2. Trace element analysis of flint mine products. Al/Mg. Site abbreviations as in Fig. 1.

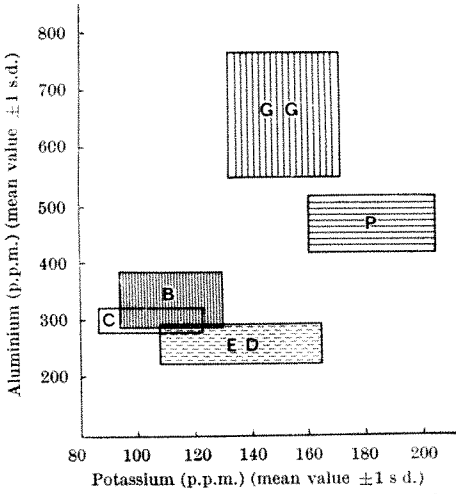

Fig. 3. Trace element analysis of flint mine products. Al/K. Site abbreviations as in Fig. 1.

a graphite counter electrode in a d.c. arc. The spectra were recorded photographically using a rotating stepped sector and a Hilger and Watts large quartz spectrograph. Silicon was used as an internal standard and suitable line pairs were measured using a Joyce Loebl 'Mark III C' microdensitometer. The method is relatively insensitive because of the suppressive effect of silica on the spectral lines of the other elements present, and suffers from the poor reproducibility which is inherent in d.c. arc methods. Consequently it was possible to measure only the major impurities and the results showed a relatively high coefficient of variation of 20 per cent on replicates of the same sample. Nevertheless, in spite of these limitations, the results indicated that differences in the levels of major impurities in flint from flint mines might be used as an indication of place of origin. Aluminium, calcium, magnesium, iron and manganese (and phosphorus from one site) were detected by this technique, but in view of the general lack of sensitivity and suspected systematic errors, particularly in the case of aluminium, other methods were investigated.

We then turned our attention to atomic absorption spectroscopy, which requires the samples to be in solution. The flint powder, produced as before, was digested on a water bath with a mixture of hydrofluoric and perchloric acids in a 'Teflon' beaker. There was a small black residue in each of the resulting perchlorate solutions; some of these residues were analysed on the spectrograph and it was inferred from the general absence of spectral lines that they were probably composed of elemental carbon and certainly would not contribute to the analytical results. After centrifugation to remove these residues, the solutions were analysed for aluminium, iron and magnesium with a Hilger and Watts 'Atomspek' atomic absorption spectrophotometer, using a nitrous oxide acetylene flame for aluminium, and an added excess of lanthanum chloride for the determination of magnesium in the presence of aluminium. The alkali metals were also found to be present, and consequently sodium and potassium were determined using an EEL flame photometer. The analyses by both these methods presented no difficulties, and results could be estimated with a much higher accuracy than that obtainable by emission spectroscopy. The atomic absorption method can clearly be extended to other elements because qualitative spectrographic examination of residues from the hydrofluoric acid treatment of 0·5 g quantities of prepared flint has shown that up to twenty elements (including Al, Sb, Be, Ca, Cu, Ge, Fe, Pb, Li, Mg, Mn, P, K, Ag, Na, Sr, Sn and Ti) can occur in these samples.

The results for aluminium by atomic absorption spectroscopy were shown to be much more reliable than those obtained by emission spectroscopy and all the aluminium results quoted and discussed later relate to the atomic absorption technique. No systematic differences were, however, found between the two methods in the case of magnesium and iron, and the results by the two methods have therefore been combined in the figures. This is regarded as being valid because the spread of results from flint to flint at any one site is much greater (a coefficient of variation of 50 per cent) than the variation inherent in the two methods of analysis.

Thus in the discussion which follows, the results previously obtained by emission spectroscopy are combined with the results since obtained by atomic absorption on fresh flints. The sodium and potassium results were all obtained by flame photometry. Complete results are not yet available for Le Grand Pressigny and Spiennes, but the initial spectrographic examination has already revealed that Spiennes samples can be uniquely identified by their high levels of phosphorus, which was not detected by this method in samples from the other sites, and, similarly, flints from Le Grand Pressigny are uniquely characterized by very high levels of iron content.

The results shown in Figs. 2, 3 and 4 are the mean values for each element determined in the twenty samples taken from each site. Work is currently in progress

on the estimation of Li, P, Ba, Ti, in order to provide further criteria for the differentiation of flint mine sites.

Statistical Analysis of Chemical Data

Complete data for the concentrations of Al, Mg, K and Fe in samples from six localities were available for this preliminary study. The results were first studied graphically, by plotting the concentration (in p.p.m.) of one element against another (Figs. 2–4). These plots showed that some localities occupied distinct fields; for example, in Fig. 2, Grimes Graves is distinct from the others, showing only a slight overlap. Other combinations of elements in other localities are equally or more clearly distinct (for example, Fig. 3). As a result of this preliminary study it was decided that some more sophisticated analysis of the data should be carried out and we used factor and discriminant analysis: we used a standard method and the data were processed on the University of London CDC 6600 computer, using modified versions of the programs given in the IBM 'System 360' manual[9].

Discriminant functions were calculated on the raw data and the *a priori* classification was subsequently tested by determining the group to which an individual flint was best assigned using the calculated coefficients. By this means it was found that 85 per cent of the individual flints were correctly classified. The majority of those that were incorrect belonged to the Cissbury/Black Patch sites which make up the South Downs group. Geologically this would be expected because the two sites are close together and the flint used could have been extracted from similar levels in the Chalk. A second set of functions was calculated after combining the Cissbury/Black Patch data; the new set of discriminant functions, when applied to the data, showed that the *a priori* classification was now 95 per cent correct.

The factor analysis was performed using the method of principal components, and, because the resulting matrix was easily interpreted, no rotation was needed. The results are summarized in Table 1; the first two factors only are reported and these account for 68 per cent of the variation in the data.

Table 1. SUMMARY OF FACTOR ANALYSIS

Factor 1	Factor 2
Al +ive correlation with K Al −ive correlation with Mg K −ive correlation with Mg	Fe not correlated with either Mg, Al or K

The results of both techniques are provisional until more data from the five sites (and further new sites) are available. The discriminant function analysis indicates, however, that our method, using trace element data to identify flint implement source areas, may be valid. The non-ferrous trace elements which we used are probably accounted for by the presence of clay minerals incorporated in the flint during its formation, which would explain the correlations found in the factor matrix.

Glassy Particles in Lunar Fines

by

GEORGE MUELLER*
GERTRUDE W. HINSCH

Institute of Molecular Evolution,
University of Miami,
Coral Gables, Florida 33134

Most of the Apollo 11 glassy particles differ from those generated by terrestrial volcanism, by meteoritic impacts, or by the condensation of the parent bodies of meteorites. Some of the particles may have been formed by the action of solar flares on the lunar surface.

To begin with, we describe the morphology and optical properties of the Apollo 11, sample 86 of lunar fines and samples 91·8 and 19·9 of the conglomerates as observed with Wild petrographic and Leitz phase contrast microscopes and a Cambridge 'Stereoscan'. Chemical composition was studied with a microspectrophotometer[1] and the Philips electron microprobe. Scanning microscopy was done on gold-coated particles attached to rivets.

Most of the glass particles are of either regular or pumiceous habit. Each gram contains approximately 5×10^6 regular and 7×10^6 pumiceous particles with sizes of 1 to 1,000 μm (Table 1). The regular particles include globules, prolate and oblate spheroids, ellipsoids, dumbbells, dumbbells with central bulge, rings, crescents, tops, spindles, filaments and tear drops (Figs. 1–5, 6*A*). The pumiceous particles are asymmetrical and rugged (Fig. 6*B*). Aggregates of two or more particles are rare (Figs. 3, 7) and resemble some of the twin and grapebunch chondrules[2] from carbonaceous meteorites. A globule adhering to a glassy fragment by a slender protrusion has been observed (Fig. 1).

The prolate spheroids and dumbbells often have zonation patterns (Fig. 8) and flow lines of crystallites (Fig. 8*A*). Gas inclusions occur in the central portions of light, intermediate, or dark shaded glass particles (Fig. 8*B*). Towards the extremities of some of the particles, a zone

of orange occurs next to a zone of dark brown (Fig. 8*B*). The orange coloured glass is not seen in any unzoned particles. Numerous particles are tipped with minute biconvex grains of troilite and, more frequently, nickel–iron (Figs. 4, 8*A*). Zonation may be restricted to only one extremity, which is usually narrower than the opposite one (Fig. 8*C*). Elongate particles in which one extremity is occupied with a gas inclusion tend to taper towards the opposite end (Fig. 8*D*). Occasionally, crystalline silicates occupy the extremities of the elongate particles. These may be rather symmetrically displaced in alternate sides of the long axis of the particles (Fig. 9). Some of the oblate spheroids have a more or less regular zone of darker glass or inclusions of nickel–iron along the equatorial regions (Fig. 11*B*).

Several rare regular particles (less than 1 p.p.m.) from the most globular 0·1 per cent fraction of specific gravity > 3·4 fraction yielded a few magnetic particles with an octagonal outline (Figs. 10*A*, *B*, *C*). These resemble the microchondrules of magnetite in type I carbonaceous chondrites[2]. The more angular and flattened fraction of the same density range contained some hexagonal plates of troilite (Fig. 10*D*).

Particles may be covered by semitransparent films of nickel–iron. Surface dimples and inclusions of nickel–iron, troilite, glasses of high refractive index, or crystalline silicates are common (Figs. 11, 12). Most particles with crater-like pits contain a high proportion of gas inclusions (Fig. 8*D*). Rare globules of colourless to pale blue glass contain octahedra of an opaque or a slightly translucent spinel (Fig. 13*A*).

Many globules have stalk-like appendages (Figs. 6*A*, 13*A*). The elongate forms with appendages are markedly asymmetrical (Fig. 13*B*). A count of 561 transparent particles in unsorted fines showed 196 particles with no appendages, 318 particles with one, 40 particles with two, and 7 particles with three or more. Inspection in polarized light indicates that approximately 3 per cent of the glassy particles are partly or wholly recrystallized. The conglomerates contain about 15 per cent recrystallized particles.

The glasses may be colourless, light yellow, blue or green, or dark brown. Opaque glasses of sky blue, brown and black shades are also present. They have densities of 2·6 to 3·2 and many of the relatively denser ones are magnetic. Table 2 shows the relations between morphology, shade, density and magnetism of the glasses.

Preliminary electron microprobe analysis[3] has revealed glassy regular particles of salic, mafic or basaltic composition. The pumice particles are of relatively more uniform basaltic composition. The crinkled surface of a fragmented spherule was found to be rich in Mg, Al, Si and some Zr.

Table 2. RELATIONS BETWEEN COLOUR, DENSITY, MAGNETISM AND MORPHOLOGY OF PARTICLES OF THE FINES

Sieving fraction (μm)		Percentage spheroids with eccentricity of 0–10 per cent	10–50 per cent	Over 50 per cent	Percentage dumbbells	Percentage rings	Percentage tear drops
	Shade						
44–53	Light	79	12	4	1	4	0
	Dark	56	28	9	1	3	3
	Opaque	51	24	13	6	1	5
	Spec. gravity						
10–105	Below 2·85	68	15	9	4	2	2
	Above 2·85	59	22	9	4	4	2
	Magnetism						
5–53	Less magnetic 5 per cent	60	25	6	5	1	3
	More magnetic 95 per cent	51	23	12	7	3	4

Microspectrophotometric analyses of the salic particles in the visible and near ultraviolet show a continuous absorption spectrum increasing towards the ultraviolet. The darker particles have the same type of spectrum with a higher percentage absorption. The spectra of basaltic pumices from Hawaii and the Orgueil meteorite are similar to that of the average lunar pumice. A blob of orange glass from the terminal portion of a zoned prolate ellipsoid showed a maximum absorption feature at 340 μm which was absent from the spectra of the fourteen unzoned particles.

There are deep cavities in some particles filled with foreign grains. A single microshattercone of brown glass was observed (Fig. 14). Most of the particles show little or no internal fragmentation.

The lunar pumice is characterized by irregular vesicles containing quantities of loosely anchored particles (Fig. 15*A*). Tubules of glass protruding from the main mass have been also reported[4]. By contrast, vesicles of terrestrial pumice tend to be more regular and free of attached particles (Fig. 15*B*).

Interpretation of the Structures

The gross morphology of either the regular or the pumice particles clearly indicates the solidification of freely suspended liquid or viscous liquid droplets. These

may be termed spray particles Someø of the particles may have been partially or wholly recrystallized during the course of relatively slow cooling or metamorphosed subsequent to cooling.

The small proportion of partially sintered particles of the grape-bunch type suggests condensation of the spray from tenuous incandescent clouds in which the probability of collision–coalescence was small.

The morphologies of the regular glass particles suggest their solidification at various stages of centrifugal deformation from a molten state. Elongated forms may be produced when a rotating globule develops two diagonal centres of gravity such as spheroids, ellipsoids, dumbbells, and finally filaments and tear drops as the dumbbells split. The splitting of the dumbbells would convert the rotational momentum to linear momentum with the reversion of the tear drops so formed to a globule. As long as the force which causes rotation prevails, the elongation–division process could continue until a size is reached in which capillary forces on the surface would prevent further elongation. The constancy of ratios between globular and elongate forms throughout a range of diameters (see Table 1) supports this hypothesis of the rotational origin of the forms through the action of a sustained and uniform force. The momentum required for the elongation increases with decreasing dimensions of the particle, because of the increase of capillary forces. Thus, if rotation of the sprays occurred as a single event, such as a meteorite impact or a volcanic explosion, it would be anticipated that, statistically, the larger spray particles would have received the more intensive centrifugal deformation effects and, accordingly, the elongation ratios would increase with diameter. But the increase with elongation of magnetism and the density and darkening colour (Table 2) cannot be accounted for by any theory of random impact or explosive volcanism, because such processes would not have a selective effect. Rotational momentum caused by radiation or an electron flux might account for the higher elongation ratios of the more magnetic particles, or the darker and denser particles which are usually optically less homogeneous.

Free rotation of markedly homogeneous glasses may not produce two diagonal centres and, therefore, might lead to the formation of oblate spheroids, crescents and rings. Top or spindle shaped particles may form through their rotation in a viscous state on the lunar surface.

The zoning of spheroids and dumbbells suggests that the constituents of the particles separated through centrifugation. Some of the constituents may have been present as immiscible phases in the original particle. The orange coloured glass, however, which is only present in the centrifuged structures, may be a product of centrifugation of an originally homogeneous glass. The clockwise or anticlockwise displacement of extremities from the long axis of elongate particles may indicate the occasional presence of a slightly resistant medium, possibly a tenuous gas, within which the particle rotated.

The grains of magnetite and troilite seem to be products of desublimation of ultimate lunar or meteoritic origin. The surface patterns of nickel–iron and troilite seem to indicate a lunar condensation process of the vapours of the respective substances.

The prevalence of pits on particles which are also rich in gas inclusions indicates that most of these pits were produced through bursting of some of the gas inclusions before the final solidification of the globule.

The marked prevalence of a single sintered or fused appendage of each regular spray particle seems to indicate that the hot particles settled on the lunar surface at low velocities, without much bouncing or other high velocity impact effects. The results of preliminary electron probe work suggest that the relatively volatile elements evaporated from the surface of some of the spray particles after their solidification. The relatively higher proportion of recrystallized spray particles in the conglomerates indicates that these may be older or more metamorphosed than the fines.

The lunar pumice sprays may have been formed by the heating of relatively larger masses of silicates. The more irregular character of the vesicles, when compared with the average terrestrial pumice, may possibly result from the lower gravitational field of the Moon. Loose protrusions and particles within the vesicles would not settle and fuse to the walls before the cooling of the melt.

Sprays from the Moon and from Other Sources

Particles transitional between the regular, the pumiceous and the rare types are uncommon, and it is conceivable that each type was produced in different conditions. The modes of formation of spray particles of terrestrial or extraterrestrial origin so far suggested include primary condensation of celestial bodies, volcanism and meteoritic impact. Terrestrial volcanic sprays differ from most lunar particles by a marked degree of chemical homogeneity and by the lack or rarity of symmetrical rotational forms[2]. The absence of flattened rotational forms is particularly significant because the development of such forms could not be efficiently damped by the terrestrial atmosphere.

The glassy particles from Apollo 11 show relatively few structures which can be recognized as due to impact.

The terrestrial meteoritic impact particles contain symmetrical, chemically rather homogeneous globules of glass, many with opaque cores[5]. There are no rotational forms. The meteoritic microchondrules and chondrules have been interpreted recently as condensates from the solar nebula[6], or products of incandescent clouds which constituted the mantles of condensing asteroid-type parent bodies[2]. The chondrules are characterized by the absence of rotational forms and a high incidence of sintered and coalesced aggregates[7]. Only some of the rarer structures from the Apollo 11 material show any detailed resemblance to chondrules. Such structures include some partially crystallized glassy particles[8], magnetite grains and grape-bunch type aggregates. The cosmic spherules from the ocean bottoms and other locations show a high degree of recrystallization with no pronounced rotational structures[9].

Tektites and microtektites[10] are believed to be products of impacts on the Earth[11] or the Moon[12]. Although the rotational forms of tektites more closely resemble the rotational forms of lunar particles than the other forms, they differ from the bulk of the Apollo 11 particles in having a less basic mean chemical composition and a greater degree of homogeneity.

Theoretical Considerations

Might solar radiation explain the origin of the lunar glassy particles? It was predicted before Apollo 11 (ref. 13) that because of the increased solar radiation in vacuum, the mainly basaltic lunar surface would become depleted in Na, K and organic molecules. Gold[14] has attributed the glassy sheets seen in craters to fusion by solar flares of unusual intensity. Loose particles on the lunar surface would need relatively less radiation to melt because heat would be conducted away only through narrow contacts with the rest of the lunar material. If the exceptionally intensive solar flare is powerful enough to fuse the concave portions of the lunar surface, it would therefore also be adequate to melt loose particles. Some of the fused particles would remain on the lunar surface. The heat escaping through their narrow contacts would sinter the dust particles beneath and produce the characteristic appendages. Thermal decrepitation before melting would throw up other particles from the surface. Such particles would eventually melt in a suspended state, and the high electron flux and radiation would cause the rotational forms throughout a broad range of particle diameters.

This hypothesis is also supported by the existence of particles of both salic and mafic composition. Our terrestrial sprays clearly indicate that both volcanism and meteorite impact involve the production of homogeneous or quasi-homogeneous glasses. A hypothesis of glass formation through hypervelocity impacts of minute cosmic particles may possibly account for the chemical diversity of the spray, but according to this theory one may expect a higher than observed degree of other impact structures. The extreme composition range of the lunar sprays can be most readily explained by solar flares melting minute, essentially monomineralic particles on the lunar surface.

The conditions of vacuum and high electron flux of the lunar surface have been simulated with the electron microscope. Fox *et al.*[3] reported that the focusing of the electron beam of lunar fragments results in sintering and the formation of globules with dimples and bud-like protrusions on their surfaces.

The solar flare origin implies the possibility that the reported depletion of volatiles in the lunar basalts from Apollos 11 and 12 would be at least partially caused by solar evaporation. A decrease of spray particles and an increase of volatiles, including organic molecules, may therefore be anticipated with increasing depth beneath the lunar surface, and also at the surface of those areas which were not close to the equator at any time in the history of the Moon.

Comments on the Big-bang

by

E. R. HARRISON*

Institute of Theoretical Astronomy, University of Cambridge

Is the big-bang hot, warm or cold? And are galactic masses determined by the interplay of gravitational and strong interactions in the very early universe?

MANY of the most intriguing problems encountered in big-bang cosmology are concerned with the nature of the very early universe. Elsewhere[1-3] it is suggested that cosmology and high energy particle physics are intimately related during the earliest moments of the expanding universe, and that large structures such as galaxies already exist in primitive form. In this discussion comments are made on the problem of whether the big-bang is hot,

*On leave from the Department of Physics and Astronomy, University of Massachusetts, Amherst, Massachusetts 01002.

warm or cold, and on the possibility that galactic masses are determined by the interplay of gravitational and strong interactions.

From the present average values of the baryon, lepton and photon densities it is possible[4-6] to follow roughly the changing composition of the universe back to the onset of strong interactions at a density and temperature of

$$\rho_\pi \sim m_\pi/\lambda_\pi^3 \sim 10^{14} \text{ g cm}^{-3} \quad (1)$$

$$T_\pi \sim m_\pi c^2/k \sim 10^{12} \text{ K} \quad (2)$$

where $\lambda_\pi = \hbar/m_\pi c$ is the pion wavelength, and symbols have their usual meaning. If time is measured from a singularity of infinite density the "hadron era" terminates at

$$t_\pi \sim (\lambda_\pi^3/Gm_\pi)^{1/2} \sim 10^{-4} \text{ s} \quad (3)$$

One might, with perhaps pardonable audacity, refer to the universe in the period $t > t_\pi$ up to the present epoch as the "known" universe. But before t_π the universe is "unknown", and our theories of its composition and nature are highly uncertain and speculative. The hadron spectrum is known only at relatively low energy and there is no generally accepted theory of the properties of matter at extreme densities and temperatures. Moreover, the universe may be far from uniform, and attains ultimately its homogeneous and isotropic state through interconnexions opened up by "mixmaster" convulsions, as proposed by Misner[7]. (Daroshkevich and Novikov, however, in an unpublished paper, find that non-uniformities do not entirely disappear by this method.) Alternatively, the global homogeneity and isotropy of the universe may derive from an initial underlying uniformity of a primordial chaos at the threshold epoch of classical cosmology[1,2]

$$t^* \sim (G\hbar/c^5)^{1/2} \sim 10^{-43} \text{ s} \quad (4)$$

when the density is

$$\rho^* \sim c^5/G^2\hbar \sim 10^{93} \text{ g cm}^{-3} \quad (5)$$

and the hadron gravitational and strong interactions are of comparable strength. Before t^* there exists the physically indescribable chaos of quantum cosmology[1]. According to this hypothesis all astronomical structure on the galactic scale evolves from the fluctuations of the primordial chaos[3].

One might adopt the attitude that $t < 10^{-4}$ s is only a fleeting moment and ask: why therefore bother with it? But from the point of view of logarithmic time, which possibly is more meaningful, the known universe of $40 \lesssim \log t/t^* \lesssim 60$ is of shorter duration than the hadron era of $0 \lesssim \log t/t^* \lesssim 40$. Or one might argue that in the hadron era the universe may be totally unlike anything hitherto imagined, and ask whether it is sensible to discuss so speculative a subject. From time immemorial man has wondered about the origin of the universe, and no doubt he always will. Apart from man's usual motives for speculating on such an obscure subject, the big-bang is itself a fascinating subject for study. And at the present moment rival theories of the early universe offer us an interesting choice between hot, warm or cold big-bangs.

An equation of state frequently used for extreme densities is

$$p = (\gamma - 1)c^2\rho \quad (6)$$

where p is an isotropic pressure, and γ is a constant in the range $1 \leq \gamma \leq 2$. There are reasons for thinking[8] that in fact $1 \leq \gamma \leq 4/3$, despite arguments[9] favouring an upper limit of 2. If thermodynamic equilibrium is assumed, the temperature in the early universe is[6]

$$T \propto \rho^{(\gamma-1)/\gamma} \propto t^{2(1-\gamma)/\gamma} \quad (7)$$

and therefore rises with density when $\gamma > 1$. (If the density of hadronic states increases as some power of particle mass, then[10] $1 \leq \gamma \leq 5/4$.) This is the hot big-bang theory, and at the threshold epoch the temperature for $\gamma \leq 4/3$ is $T \leq T^*$, where

$$T^* \sim (\hbar c^5/Gk^2)^{1/2} \sim 10^{32} \text{ K} \quad (8)$$

Layzer[11] suggests that on the contrary the universe has initially a zero temperature. This theory postulates a complete absence of antimatter in the initial stage[12], and assumes that the 3 K microwave radiation is not a remnant of the primordial fireball. It can be argued that a cold big-bang implies perhaps a universe which must forever expand. Consider the case of a universe that first expands and then eventually collapses. Because of the 3 K radiation the collapse phase terminates in a hot big-bang[13] and this occurs independently of whether the previous big-bang is hot or cold. If now collapse is followed by renewed expansion, as in the oscillating or bouncing cosmological models, then all succeeding big-bangs are hot. The probability of being at the beginning of such a sequence is presumably very small, and therefore the cold big-bang theory limits the available cosmological models to those which continually expand.

Hagedorn[14,15] has proposed a theory of dense matter—in thermodynamic equilibrium—of great importance in cosmology. He presents a strong case in support of an exponentially increasing mass spectrum, and from this has developed the "hadronic boiling-point" theory. The exponential smallness of the number of particles in the high mass states is offset by the exponentially large number of such states, and as a result the temperature approaches asymptotically a limiting value T_π for densities large compared with ρ_π, where ρ_π and T_π are given by relations (1) and (2). Hence, according to this theory the big-bang has a temperature of the order 10^{12} K, and is "warm" in comparison with the hot and cold models.

An integration over all hadronic states in Hagedorn's theory gives a total number of particles in volume V of

$$N \sim \ln Z(V,T) \sim -\frac{V}{V_0}\ln\left(\frac{T}{T_0} - 1\right) \quad (9)$$

for $\rho \gg \rho_\pi$, where Z is the partition function, $V_0 \simeq \lambda_\pi^3$, and $T_0 \simeq T_\pi$. In place of equation (6) the equation of state is now

$$p = \frac{T}{V}k \ln Z \sim \frac{T_0}{V_0}k \ln\left(\frac{V_0\rho c^2}{kT_0}\right) \quad (10)$$

and therefore $p/\rho c^2 \to 0$ as $\rho \to \infty$. Thus a uniform universe in the hadron era is similar to the Einstein–de Sitter model. It is possible, however, that Hagedorn's theory applies only for a limited period of time in the very early universe. The integration over all hadronic states of $m_\pi \leq m \leq \infty$ is allowable as long as the Hubble distance, of order ct, is large compared with the pion wavelength. When $t < \lambda_\pi/c$, the observable universe is smaller than the pion wavelength and points separated by a distance λ_π move apart at a speed greater than c. To avoid this anomalous situation and preserve the elementarity of particles it is necessary to eliminate the particles of mass $m < \hbar/tc^2$. In other words, particles of mass $m < \hbar/tc^2$ cannot exist, and the lower mass hadron states are depopulated when $t < \lambda_\pi/c \sim 10^{-23}$ s. The hadronic boiling-point is therefore the

Hagedorn value $T_0 = T_\pi \sim 10^{12}$ K in the range

$$10^{-23} \sim \lambda_\pi/c \lesssim t \lesssim (\lambda_\pi^3/Gm_\pi)^{1/2} \sim 10^{-4} \text{ s} \quad (11)$$

$$10^{56} \sim c^2/G\lambda_\pi^2 \gtrsim \rho \gtrsim m_\pi/\lambda_\pi^3 \sim 10^{14} \text{ g cm}^{-3} \quad (12)$$

and the universe has an age of at least one chronon, or one "jiffy". (I am indebted to W. A. Fowler for the term "jiffy", who recalls that it was used by R. C. Tolman for the time light takes to travel a distance of 10^{-13} cm.) When the age of the universe is less than one jiffy, Hagedorn's theory still applies, but now $V_0 \sim (ct)^3$ and the hadronic boiling-point is $T_0 \sim \hbar/kt$. Hence, as we go back in time from 10^{-4} s to 10^{-23} s the big-bang is warm and has roughly a constant temperature of 10^{12} K. And then, at earlier epochs, the temperature rises as $1/t$ and ultimately attains the original value given by relation (8) of 10^{32} K at the threshold epoch. To the question whether the big-bang is hot, warm or cold, the answer is that perhaps at first it is hot, and is then warm for most of the time.

Density fluctuations in the Hagedorn theory are of the form

$$\frac{\delta\rho}{\rho} = \alpha\left(\frac{V_0}{V}\right)^{1/2} \sim \left\{\frac{1}{N}\ln\left(\frac{T_0}{T}-1\right)^{-1}\right\}^{1/2} \quad (13)$$

(where $\alpha \sim 1$) and are of the order unity in volume V_0. In the warm era of the big-bang the nucleon volume V_0 is small compared with the observable universe, and equation (13) may be used for $V_0 \lesssim V \lesssim (ct)^3$. But in the earlier hot era, $V_0 \sim (ct)^3$, equation (13) tells us that fluctuations are of order unity within the observable universe, and is unable to specify the fluctuation spectrum for wavelengths λ greater than ct. The fluctuation spectrum for $\lambda > ct$ is in a frozen state, and is essentially a relic of the fluctuations prevailing at the threshold epoch. Let $\delta\rho/\rho = \beta(N)N^{-n}$ be the fluctuation spectrum at the threshold epoch, where $N = V/V^*$ is the number of particles in volume V, and $V^* \sim (ct^*)^3$. In order that these fluctuations develop into galaxies it is shown[2] by arguments of a quite general nature that $n = 2/3$, and $10^{-2} < \beta_g < 1$, where β_g is for galactic masses. It is also shown semi-quantitatively that metric fluctuations at the threshold epoch have the remarkable property of obeying the $n = 2/3$ rule. A weakness of the theory, however, is its inability to determine $\beta(N)$ and therefore, in principle at least, galaxies of all masses are possible. But if, as a result of the initial fluctuations or even possibly convulsive oscillations, it is possible for weak correlation to exist (weak in the sense $\alpha \ll 1$) over distances larger than a pion wavelength, then β will tend to maximize at wavelengths of the order λ_π owing to pion interactions, as in Hagedorn's theory. This leads to the surprising conclusion that the mass contained in a nucleon volume of λ_π^3 at the threshold epoch is ultimately the typical mass of a galaxy. A mass M in the primordial fireball becomes ultimately a material mass of[6] ηM, where $\eta \sim b(\hbar c/kT)^3$, b is the present average density of nucleons, and $T \simeq 3$ K is the background radiation temperature. Hence the ultimate material mass in an initial nucleon volume is

$$M_g = \eta\rho^*\lambda_\pi^3 \sim 10^{44} \text{ g} \sim 10^{11}\, M_\odot \quad (14)$$

for $\eta \sim 10^{-10}$. Because η is of the same order as the dimensionless number $(Gm_\pi^2/\hbar c)^{1/4}$, equation (14) can be expressed as

$$M_g \sim m_\pi(\hbar c/Gm_\pi^2)^{7/4} \quad (15)$$

and forms an interesting contrast to a solar mass of $M_\odot \sim m_n(\hbar c/Gm_n^2)^3$ [2] where m_n is the nucleon mass. What determines the baryon number constant η is, of course, unknown. But it is interesting to notice, nonetheless, that stellar masses are governed by gravitational and Coulomb interactions, whereas galactic masses may be determined primarily by the interplay of gravitational and strong interactions in the very early stages of the big-bang.

I thank W. A. Fowler, M. J. Rees and G. Steigman for helpful remarks. This research was supported in part by the US National Science Foundation.

Generation of Cherenkov Light Flashes by Cosmic Radiation within the Eyes of the Apollo Astronauts

by

G. G. FAZIO

Smithsonian Astrophysical Observatory and Harvard College Observatory, Cambridge, Massachusetts

J. V. JELLEY
W. N. CHARMAN

Nuclear Physics Division, AERE, Harwell, Berkshire

It is proposed that the primary cosmic radiation is responsible for the light flashes observed by astronauts in translunar flight. Cherenkov radiation may be an important or even the dominant mechanism. An alternative mechanism is the direct excitation of the retina by cosmic ray particles.

CREW members of Apollos 11, 12 and 13 have reported the observation of flashes of light within the command module during the long periods of translunar flight (private communication from D. E. Hagge). In this article we suggest that because nearly all the observations were reported to have occurred when the eyes were closed, the flashes are probably caused by primary cosmic ray particles which penetrate the cabin walls and the astronauts' eyes. Two mechanisms are proposed here, the first that the flashes arise from Cherenkov radiation generated

Table 1. ASTRONAUTS' OBSERVATIONS

Flight	Astronaut	Observations
Apollo 11*	Edwin Aldrin	All incoming light blocked by shades, spacecraft revolving; pinpoint-like flash that dissipated rapidly; single flash, white; frequently streak, occasional double flash; random location; saw them at will; static electricity not the cause; never recalled seeing them with eyes closed
	Neil Armstrong	Saw approximately 100 flashes; rate about one per minute
Apollo 12*	Charles Conrad	Observed flashes with eyes closed; approximately 10 per cent of flashes were streaks and double points; streaks appeared horizontal; all streaks appeared in the upper field of view
Apollo 13†	General comments	Each crewman saw light flashes, but only while in the dark and with the eyes closed. All observations were made in the command module, both in and under the couches. None of the flashes were obtrusive. The crewman had to be relaxed before he noticed them. They observed many more dots than streaks, and the colour was always white
	James Lovell	Frequency of flashes about once every two minutes
	Jack Swigert	Counted only two flashes in one half hour
	Fred Haise	First evening counted 10 flashes in a 5-min period; time intervals varied from 7 s to 1·5 min; all but one flash were dots that looked like "roman candles"; in this set there was one streak which passed from left to right; the second night 12 to 15 flashes observed before falling asleep (time interval not defined)

* Comments by Astronaut Edwin Aldrin, recorded by G. G. Fazio; also private communications with D. E. Hagge.

† From memorandum by Astronaut Anthony England on debriefing of crew of Apollo 13.

in the ocular media or the retina of the eye or, alternatively, that the receptors or their accompanying cells in the retina are excited directly by ionization. We shall discuss chiefly the former mechanism.

There is already evidence[1], at a reasonable statistical significance, that even sea level cosmic radiation, chiefly μmesons, can be detected by the Cherenkov radiation which they produce in the vitreous humour of the eye. At the same time, however, it was pointed out that the observed effects could possibly be attributed to fluorescent light in the vitreous humour or even direct excitation, either of the optic nerves or the areas of the brain associated with vision.

All the observations so far on the Apollo flights have been in translunar flight, and never in Earth orbit or lunar orbit. On Apollos 11 and 12 the observations were reported without the astronauts receiving special briefing before the flights, but on Apollo 13 the astronauts had received special instructions before the flight, so that their reports may be more reliable and detailed than was the case for the two earlier flights.

The observations, taken straight from the astronauts' notes and amplified in debriefing interviews, are listed in Table 1.

Cherenkov Radiation in the Ocular Media and Retina

A single primary cosmic ray charged particle of atomic number Z and velocity βc will produce Cherenkov radiation in the ocular media of the eye at the rate

$$dN/dl = 2\pi\alpha Z^2 \sin^2\theta \int(1\lambda^{-2})d\lambda \text{ photons cm}^{-1} \qquad (1)$$

where θ, the Cherenkov angle, is $\theta = \cos^{-1}(1/\beta n)$ (ref. 2). For the vitreous humour of the eye, $n = 1{\cdot}34$, so that the threshold kinetic energy for protons is 470 MeV, $\theta(\max) = 42°$, and the asymptotic value of $dN/dl = 210$ photons cm^{-1}, over the band $\Delta\lambda = 3800$ to 6200 Å. The duration of the flash will depend on geometrical factors, but is always $\leq 10^{-10}$ s in this case, that is, short compared with the integration time of the eye, ~ 50 ms.

The response of the eye to this internally generated light will depend on a variety of factors, physical, physiological and psychological. As well as the wide fluctuations which always arise in numerical data in this field, there are additional factors because of the unusual environment in translunar or orbital flight.

First consider a relativistic proton passing through the centre of the eye and striking the retina normal to its surface. Because the light is at best of very low intensity, we shall be concerned exclusively with scotopic (rod) vision, and because the cosmic ray particles will usually arrive with a random orientation, we can neglect the foveal region of the eye and consider mainly the peripheral regions. Near threshold the retina exhibits an areal integration, but this is sufficiently restrictive to limit the effective path length of the particle and hence the maximum available light. Various values appear in the literature for the effective area of integration in scotopic vision. We will here adopt 20′, quoted[3] for the diameter of the basic unit, the area believed to be served by a single ganglion cell. For the Cherenkov radiation considered here, the light flux falls off as $(1/r)$ from the impact point of the particle on the retina. In these circumstances both physiological summation and probability summation[4] will play their part in extending the effective area. This suggests that 2° may be a reasonable value to take for the effective diameter of the area of integration in this particular problem. With a posterior–nodal distance of 17 mm, this corresponds to an absolute radius of 0·29 mm on the retina (Fig. 1) so that the effective track length Δl is only 0·32 mm. We note that this is comparable with the figure for the thickness of the retinal layer itself, typically 0·36 mm (ref. 5), so that the effective portion of the particle track occurs within the retinal layer itself rather than in the vitreous humour in front; the effective part of the Cherenkov cone is thus formed in and among the various layers of cells and their synapses. The larger portion of the cone which develops throughout the vitreous humour and the other ocular media is therefore relatively ineffective.

For the absolute sensitivity for the dark adapted eye, we take the figures obtained by Hecht *et al.*[6], namely, that 5–14 quanta are required at the retina to produce a signal from a 1 ms flash at $\lambda = 5100$ Å on a 10′ diameter area, with a 60 per cent probability of detection. At the present level of approximation we will adopt a figure of 10 photons for the threshold sensitivity, somewhat higher than the limit of 4 photons quoted in some later work[7].

With these values of (dN/dl), $\Delta\lambda$ and Δl, 6·7 photons on average are thus available, per proton ($\beta = 1$), on the elemental area. The effective number of photons is then given by $6{\cdot}7\ (\int\lambda^{-2}L(\lambda)d\lambda/\int\lambda^{-2}d\lambda)$ where L is the scotopic luminosity factor[8] normalized to unity at $\lambda = 5100$ Å and corrected for transmission of the ocular media[9]. Using the data from refs. 8 and 9, the ratio of these integrals is 0·43, so that the average effective photon number is reduced to 2·9. This falls short of the accepted

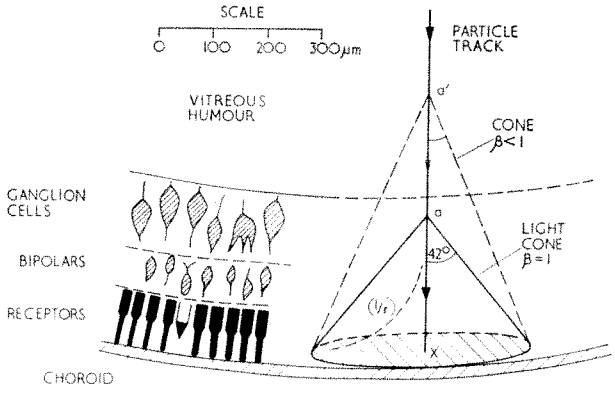

Fig. 1. Left, the essential features of the layers of cells in the human retina. Right, the formation of a Cherenkov light cone formed from a primary cosmic ray particle traversing the retina.

threshold of 10 by a factor of ~ 3, so a singly charged relativistic proton (or electron) will produce a detectable flash only once in $\sim 10^3$ impacts, bearing in mind that Hecht's threshold itself only represented a 60 per cent probability of detection.

But because the Cherenkov light yield varies as Z^2, α particles should be just detectable at the 60 per cent confidence level, while for the Li, Be, B group ($Z^2 = 9$ to 25) and the C, N, O group ($Z^2 = 36$ to 64), the available light exceeds the threshold by factors of 2·2 to 6·2, and 9 to 16, respectively. In these cases therefore the detection probability may approach unity, even with some relaxation on the requirements of no stray light and full dark adaptation.

If the particles enter the retinal layer obliquely, as the majority will, the pool of light will be ellipsoidal, with the impact point at one focus of the ellipse. With the $(1/r)$ flux distribution, the photons will cluster round the impact point, and for particles of sufficiently high Z we might expect an observer to report that the image had shape, and he might then record an "ellipse" or a "comet head". If we assume the same elemental area of integration, a disk of diameter $\sim 20'$, we find that for an iron nucleus ($Z = 26$) the area of sensitive detection may extend over an area having a diameter 7°, and that even for an oxygen nucleus ($Z = 8$) this disk will still have a finite size, a diameter of $\sim 0{\cdot}66°$.

Much of the Cherenkov light impinges on the receptors at larger angles than those which occur in normal vision, so the directional sensitivity of the rods could also be quite important. There is evidence[10] for such directivity, and it may be quite marked in this case. For particles entering the eyeball at random orientations and impinging at random locations on the retina, averaging will, however, occur, permitting much of the light to fall on the receptors at favourable angles.

On the Cherenkov interpretation of the Apollo experiments, we would not expect colour to be reported. The threshold for photopic or cone vision is ~ 800 times higher than for rod vision[5] so that if α particles are just detectable in the latter case, colour would appear only when $Z \geq 56$.

These estimates apply for particles having $\beta \to 1$. We note that for a constant area of integration, and particles with $\beta < 1$, as θ decreases Δl increases ($a'X$ in Fig. 1), so that the number of effective photons varies as $\sin^2\theta \cot\theta$. Because this function (Fig. 2) rises more rapidly with kinetic energy, above the threshold, than the normal Cherenkov yield, equation (1), it is sufficiently accurate to assume that any cosmic rays within the spacecraft cabin which arrive at the retina above the threshold will generate light at the asymptotic value of 6·7 photons per nucleon.

As already mentioned, a number of unknown factors will influence the absolute threshold in the Apollo observations. Many of these factors will combine to raise the threshold of vision, and we mention, for example, that it is known[5] that oxygen deficiency lowers the sensitivity. We do not know, however, what effects the highly enriched oxygen atmosphere of the spacecraft might have on the sensitivity.

Estimates of Flash Rates due to Primary Cosmic Ray Nuclei

The integral number of nuclei with charge Z and with energy greater than E_0 passing through the retina per unit time is given by

$$\frac{dN(>E_0)}{dt} = I_z(>E_0)A\Omega \qquad (2)$$

where I_z is the integral intensity of nuclei of charge Z in units of (cm² s sr)⁻¹, A is the effective cross-sectional area of the eye, and Ω is the effective solid angle subtended by the retina. The value of A was taken to be 3 cm². The value of Ω was determined from the density distribution of rods along a horizontal meridian of the retina. We have taken the sensitive region to be $\pm 70°$ from the fovea[4] which gives a value of $\Omega = 4{\cdot}13$ sr.

Table 2. COSMIC RAYS INCIDENT ON THE ASTRONAUTS' EYES

Primary particle	Z	Primary flux above 1·5 GeV nucleon⁻¹ (k.e.) at solar min. (m² s sr)⁻¹	Interaction m.f.p. (water) (g cm⁻²)	Flash rate (min)⁻¹	Integral flash rate for nuclei $\geq Z$ (min)⁻¹
He	2	89	39	5·1	5·6
Li	3	0·71	30	0·038	0·49
Be	4	0·31		0·017	0·45

Mg	12	0·54		0·024	0·058
Others	≥13	0·83	17	0·034	0·034

Taking the effective threshold energy for the Cherenkov radiation process to be 1·5 GeV per nucleon (Fig. 2) we have computed the number of cosmic ray nuclei above this energy at the eye of the astronaut, assuming that they have penetrated a thickness equivalent to 10 g cm⁻² of water (unpublished work of S. B. Curtis). Attenuation was considered but not secondary production. The primary cosmic ray fluxes used were based on values outside the Earth's magnetosphere at solar minimum[11]. The results are presented in Table 2 and Fig. 3.

The actual counting rate depends on the sensitivity of the retina. In ideal conditions one could detect helium nuclei with a count rate of $\sim 5{\cdot}6$ min⁻¹. Unless ideal conditions were attained it would seem that only nuclei with $Z \geq 6$ could have been detected; the calculated rate in this case is 0·38 flashes min⁻¹.

Curtis (unpublished) has computed the intensity of heavy galactic cosmic rays ($Z \geq 6$) expected at the eye of an astronaut inside the Apollo command module outside the Earth's magnetosphere. He estimated the total flux of particles with $Z \geq 6$ that could penetrate the cabin to reach the eye to be between 0·5 and 1·0 (cm² min)⁻¹ at solar minimum. These rates, considering the lower energy, are essentially consistent with our own estimates.

In these calculations the spallation products (most probably alpha particles) resulting from cosmic ray nuclei interacting in the spacecraft have been neglected. It is possible, however, that two or more nuclei resulting from spallation may pass through the retina simultaneously, producing two or more flashes.

We have also considered several other cosmic ray processes that could produce a sufficient intensity of Cherenkov light to be detected by the eye: (*a*) production of a shower of particles in the vitreous humour of the eye or in the spacecraft walls, (*b*) simultaneous passage of several protons through the eye during the integration time, and (*c*) production of Cherenkov light in the atmosphere of the spacecraft. The generation of fluorescent radiation in the spacecraft atmosphere or in the eye has also been considered. All these processes produce rates that are negligible compared with the rate caused by primary nuclei.

Direct Excitation of the Retina

It has long been known that the sensation of light (phosphene) can be produced by the effect of ionizing radiation on the retina. In most of this work (ref. 12, for example), the emphasis has been on irradiation by X-rays, in which the sensation of light is produced over the retina as a whole, under conditions in which the dosage is relatively high and the quantum energy low. The situation in space is quite different. Astronauts are exposed to

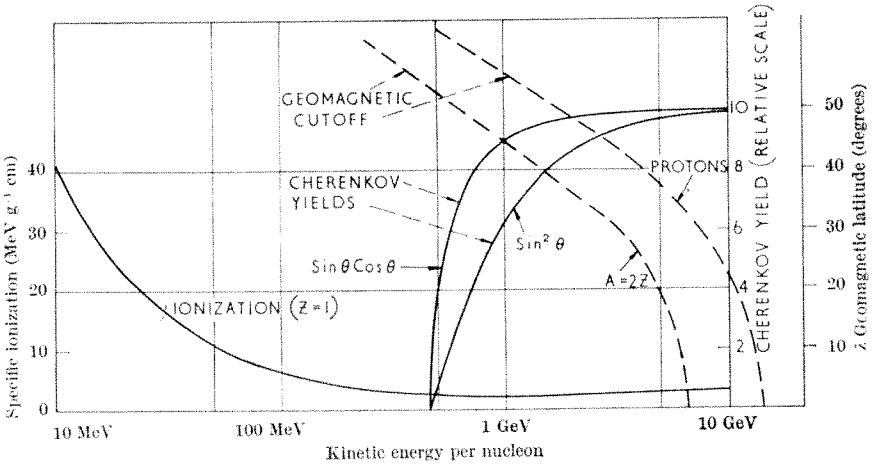

Fig. 2. The Cherenkov light yield, and the specific ionization, for particles traversing the ocular media and retina of the eye. Also shown are lines representing the rigidity cutoff imposed by the Earth's magnetic field.

high energy particles and γ-rays at relatively low fluxes. As the observers were reporting individual flashes, of limited duration and angular size, the stimuli have temporal and positional characteristics.

Fremlin[13] and Tobias *et al.* (unpublished) recently reported that faint flashes of light may be seen by dark-adapted subjects exposed to fast neutrons, in the energy regions 0–8 MeV and 20–640 MeV respectively. We ourselves have recently observed similar effects with 14 MeV neutrons, although we failed to observe such effects with 3 MeV neutrons. It is presumed that these flashes arise from ionization or excitation produced in the retina, either from recoil protons (ref. 13 and Tobias *et al.*) in the hydrogenous material of the retina (or vitreous humour) or by recoil nuclei (Tobias *et al.*) of, say, carbon, nitrogen or oxygen. The experiments are necessarily limited in scope and there is no indication as to whether the sensation is located in the receptors, the various layers of cells or their synapses, or even in the optic nerve. But they do seem to indicate that the excitation was not in the visual cortex. Although at least some of the neutrons in the work of Tobias *et al.* produced protons with energy exceeding the Cherenkov threshold ($E_p = 470$ MeV), this was not the case in the work reported by Fremlin[13]. The latter work therefore provides definite evidence that light flashes can be produced by effects other than the Cherenkov mechanism. In this case the mean neutron energy was 3 MeV, producing recoil protons with a range of about 100 μm, comparable with the length of a rod (60 μm). The observed counting rate was about 25 per cent of that computed. The specific ionization of the recoil proton is about seventy times the minimum value. The minimum value of the specific ionization necessary to generate the light flashes is still unknown, though the experiments described by Tobias *et al.*, where the mean neutron energy was 300 MeV, indicate that this may be as low as twice the minimum value. Thus in the Apollo spacecraft it is possible that cosmic ray nuclei with $Z \geq 2$ generated the light flashes by direct excitation in the retina. Crude extrapolation of X-ray data to the case of single high-energy particles, on the assumption that ionization in the retina is the only mechanism causing the phosphene, also leads to the expectation that relativistic cosmic ray nuclei with $Z \geq 2$ should produce observable effects.

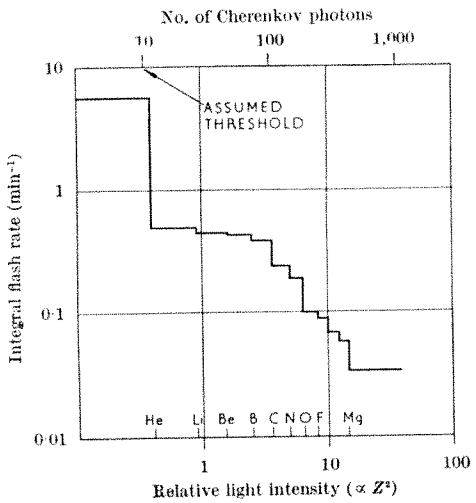

Fig. 3. The integral flash rate calculated for Cherenkov radiation produced by the primary cosmic radiation in the human eye, outside the Earth's atmosphere.

Choice of Interpretations

Of the two interpretations considered, the Cherenkov mechanism has the merit that it is possible to predict the flash rates with reasonable accuracy. The yield of light, spectrum and angular characteristics of Cherenkov radiation are all accurately known, and because the stimulus is optical and hence operates only through the light receptors, whose sensitivity is also well known, there is relatively little uncertainty in the calculations of the flash rates. The theoretical yields (Fig. 3) and the rates observed by the astronauts (Table 1) agree well, within the uncertainties imposed by their environment and the unknown degrees of dark adaptation achieved. We conclude that this mechanism may alone be responsible for the phenomenon.

The alternative mechanism of direct excitation may, however, also occur; it certainly cannot as yet be excluded, although present uncertainties prevent all but very tentative estimates from being made.

We note from Table 1 that some of the astronauts report "streaks" and "double points". Ionization and the formation of elementary Cherenkov cones occur all along the particle tracks, so "streaks" can be expected on both models for those particles which traverse the eye tangential to the retina. The streaks will, however, have a maximum length, represented by a cord tangential to the inner surface of the retina. If the eye is taken to be spherical, of diameter ~20 mm, and the retina has an effective depth of ~0·30 mm, the maximum length of cord is 4·0 mm. With a retinal scale of $1' = 4{\cdot}85$ μm, the streak of maximum length will thus subtend an angle equivalent to 17°. "Double points" can likewise be explained on both models, and may arise when a particle either intercepts the retina

of one eye at two points, or alternatively traverses both eyes in succession.

The "roman candles" referred to on Apollo 13 may also be interpreted on both models. On the Cherenkov model the effect may arise from the oblique interception of the light cones, as discussed earlier, with the clustering of photons around the focus of the ellipse. On the direct excitation model, if the phosphene is related to the specific ionization, we might expect a track to brighten towards the end of its path. We note that impressions drawn freehand by observers in the unpublished work of Tobias *et al.* could easily be identified with "roman candles".

The impressions of motion and/or directions of the flashes, pose problems, however, and we suggest that these effects are illusory.

It is tempting to suggest that the absence of observations on Earth orbital flights may be associated with the effect of the Earth's magnetic field on the primary radiation. But as we see from Fig. 2, the lines which represent the rigidity cutoff fall well to the right of the diagram, at energies above those which already give a Cherenkov yield near to the asymptotic value. We therefore feel that a more likely explanation is that on these earlier Earth orbital flights the astronauts were either too occupied, were not dark-adapted, perhaps were not wearing eye-shields, and in any case were not given rest periods long enough for the appropriate conditions to be realized.

Observations in lunar orbit would be of particular value. The astronauts could then face the lunar surface or away from the surface and, as the Cherenkov radiation is intrinsically directional, it may be possible to distinguish between this mechanism and the alternative one of direct excitation. Even for Cherenkov radiation, however, it is unlikely that a very large ratio in the counting rates would be observed for the two orientations of the astronauts' eyes, for a variety of reasons. First, the Moon obstructs only 2π of the full 4π geometry. Second, the Cherenkov cone has a very large opening angle, 42°. Third, the retinal layer extends over a large fraction, at least 2π, of the inner surface of the eye.

For nuclei of high Z, it should be possible in principle to distinguish between Cherenkov and direct excitation mechanisms by careful observations of the shape and size of the observed images. Because the lateral extent of the ionization will at most be determined by the range of the δ-rays (~ 10 μm) the size of the "points of light", or the thickness of the "streaks", will be independent of Z, so that on the direct excitation model the points and streaks will remain sharp and fine respectively, even at high Z. On the Cherenkov model, as we have seen, as Z increases the images will enlarge into circular or elliptical disks. Two factors are, however, present which are likely in practice to mask this discrimintion. In the first place the frequency of occurrence of nuclei of high Z is so low (Table 2) that the astronaut's concentration is likely to wane during the long periods of observation required, and second, even if the Cherenkov mechanism is dominant, the steep $(1/r)$ dependence of the photon flux might lead to the astronaut reporting a point rather than a disk, even for a particle of really high Z.

We thank Dr C. A. Lundquist for bringing these Apollo observations to our attention.

Polarization of Pulsar Radiation

by

R. N. MANCHESTER

National Radio Astronomy Observatory, Green Bank, West Virginia

The polarization of radiation from four pulsars has been measured and interpretations of the results are suggested.

OBSERVATIONS of the polarization of both radio and optical pulses from pulsars have been of considerable value in providing information on radiation mechanisms. These observations have generally been of the mean pulse profile as it has been shown[1] that this has a stable form, and so represents structure intrinsic to the pulsar, whereas the polarization of individual pulses varies greatly from pulse to pulse[2]. Also, it is of course possible to decrease random noise fluctuations by averaging, and so weaker pulsars can be studied.

For the Vela pulsar (PSR 0833–45) Radhakrishnan *et al.*[3] showed that the mean pulse profile was essentially completely linearly polarized and that the position angle changed continuously through the pulse. Ekers and Moffet[1], using observations at a frequency of 2295 MHz, found that most of the pulsars observed (except PSR 0833–45) were weakly polarized and that the position angle varied through the pulse, but not in a continuous way as for PSR 0833–45. Instead the position angle was found to change discontinuously between different components of the pulse. More recent observations by Komesaroff *et al.*[4] and Morris *et al.*[5] at similar frequencies have shown that for several pulsars, in addition to PSR 0833–45, the position angle varies through the pulse with no large discontinuities. For the Crab Nebula pulsar, however, Campbell *et al.*[6] observe no variation in position angle of the polarized component. It is apparent that further observations are required to resolve the important question of polarization variation in radio pulses from pulsars.

Observing System

During April 1970 polarization observations at frequencies near 400 MHz were made using the 300-feet transit telescope of the National Radio Astronomy Observatory. Observations at this lower frequency allow profiles with good signal/noise ratios to be obtained in relatively short times because of the increased pulse intensity. Comparison of these observations with those made at higher frequencies is also important.

The telescope was equipped with a travelling feed system which allowed a given source to be tracked for

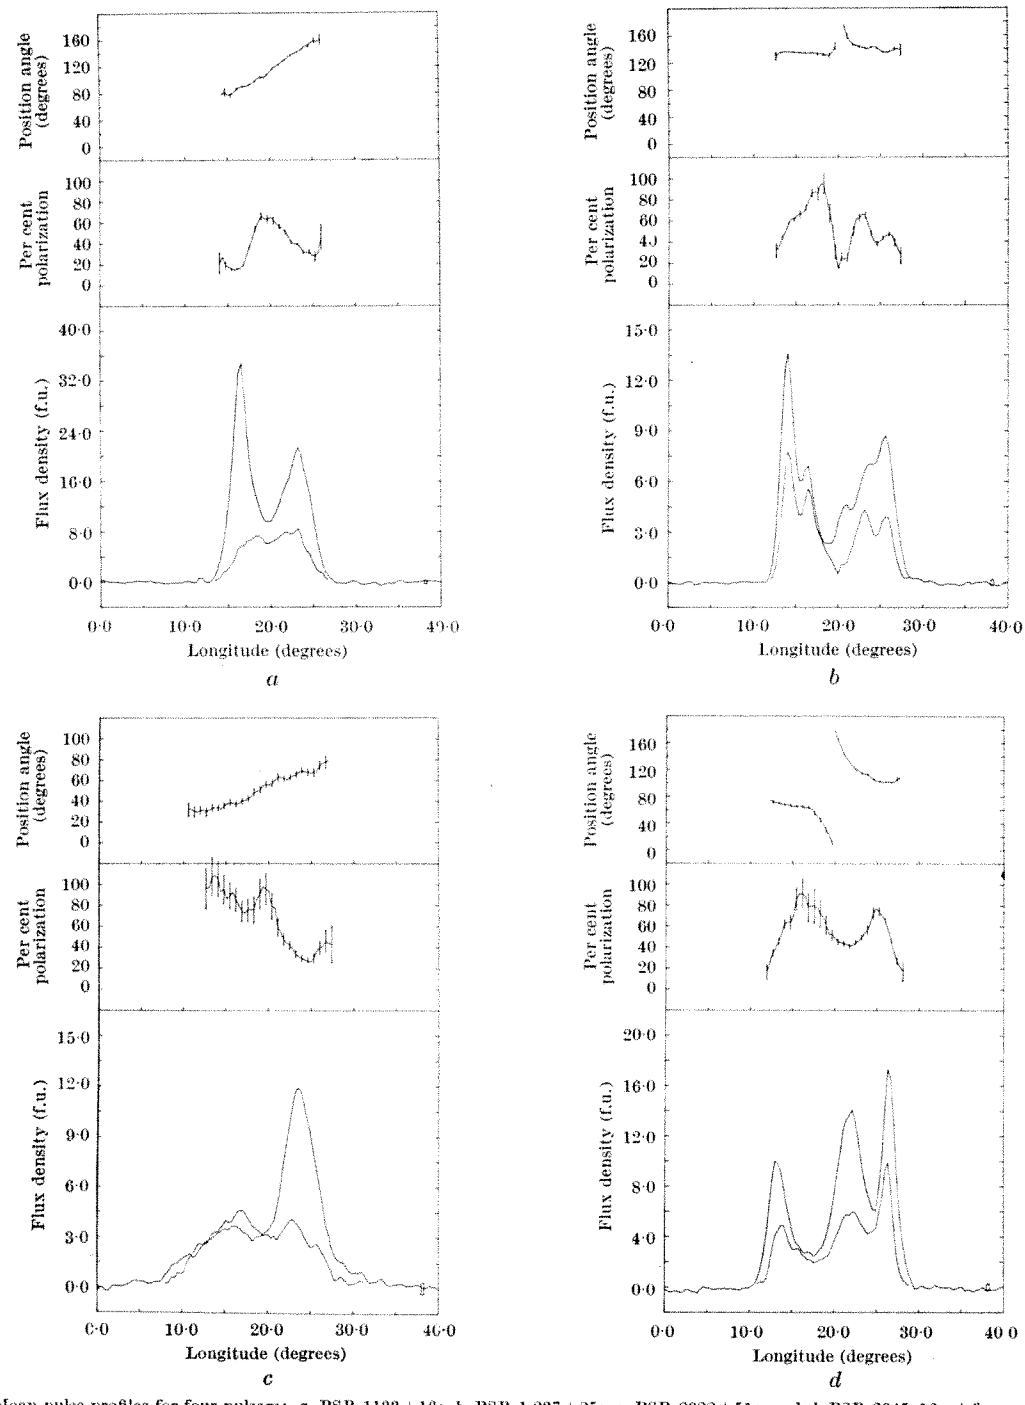

Fig. 1. Mean pulse profiles for four pulsars: *a*, PSR 1133+16; *b*, PSR 1 237+25; *c*, PSR 2022+51; and *d*, PSR 2045–16, at frequencies close to 400 MHz. On the bottom graph in each case the total intensity and intensity of the linearly polarized component are shown. Because the position angle has a 180° cycle, the variation for PSR 2045–16 is continuous through the pulse. Error bars are ±2 standard deviations.

about 40 min. Crossed dipole feeds at position angle 0° and 90° fed phase and gain matched RF amplifiers, the outputs of which were combined in a hybrid network to give four linearly polarized components (P.A. = 0°, 45°, 90° and 135°). These were amplified, band-limited and detected by four nominally identical IF systems, and the outputs recorded using a 4 × 1024 channel signal averager, giving a sampling interval of 1/1024 of the pulsar period. For each pulsar the IF bandwidth was chosen so that dispersion broadening was less than the sampling interval, and the post-detection time constant was similarly chosen approximately equal to the sampling interval. Faraday rotation within the bandwidth would not be excessive unless rotation measures were unexpectedly high. Particular attention was paid to receiver gain calibrations. A pulsed solid state noise source at the front of the receiver was recorded for a short time at intervals of about 10 min and several continuum sources were observed each day to fix the flux density scale. Recording of the redundant linear component gave a check on the gain calibrations during subsequent processing. A rotatable dipole, radiating broad band noise toward the feed from the centre of the reflector, enabled the phase response of the system to be measured.

During observations the mean pulse profile was recorded on magnetic tape at approximately 2 min intervals. In subsequent off-line analysis these profiles were calibrated and then averaged together as desired with weighting

proportional to the square of the signal/noise ratio. These averaged profiles were then combined to give the linear Stokes parameters and other polarization parameters.

Polarization Parameters

In Figs. 1*a*, *b*, *c* and *d*, polarization parameters are presented for the pulsars PSR 1133+16, PSR 1237+25, PSR 2022+51, and PSR 2045−16, respectively. The observing frequency was 410 MHz, and 384 pulses were added to form the mean profile for PSR 1133+16, PSR 1237+25 and PSR 2045−16, while for PSR 2022+51 the corresponding quantities were 392 MHz and 1280 pulses. In each case the data were recorded during an interval of about 10 min in one day. Mean pulse profiles and polarization parameters recorded at other times were not significantly different from those presented. Following Morris *et al.*[5], the horizontal axis is labelled in longitude (or alternately, phase), 360° equalling the pulsar period. In the lowest graph the total intensity, I, and the intensity of the linearly polarized component, $(Q^2+U^2)^{1/2}$, are plotted. The height of the small rectangle on the right represents the probable error ($\pm 2\sigma$) in the profiles resulting from random noise. Its width is equal to the sampling interval. The percentage linear polarization is plotted in the centre graph with $\pm 2\sigma$ error bars on every second point, and position angle is similarly plotted on the upper graph.

A number of results of interest are evident in these graphs. The percentage polarization is frequently very large—for PSR 2022+51 (Fig. 1*c*) the polarization of the leading component is essentially complete. Although the polarized component usually has peaks corresponding to peaks in the total intensity, the percentage polarization is much lower for these intense components than for the weaker regions between.

In general, the variation of position angle is continuous through the components of the pulse. In two cases, PSR 1133+16 and PSR 2022+51, the position angle varies at an approximately uniform rate through the pulse, while for PSR 2045−16 the variation is more complex but still continuous. For PSR 1237+25 the position angle is almost constant through the entire pulse (excepting the almost unpolarized central part) although the pulse has at least five separate components. The variation in polarization parameters across the pulse in these pulsars cannot be accounted for by combination of components, each having a particular position angle.

The continuous variation in position angle observed in PSR 1133+16 and PSR 2022+51 is very similar to that observed in PSR 0833−45 by Radhakrishnan *et al.*[3]. Adopting the pulsar model consisting of a rotating neutron star with an oblique magnetic axis[7–9], Radhakrishnan and Cooke[10] proposed that the radiation was originating in the vicinity of a magnetic pole with the swing in position angle resulting from a corresponding swing in the direction of the magnetic field as the star rotated. Komesaroff[11] has expanded this model in a quantitative way and shown that it can account for many of the features of pulsar radio emission. Ultra-relativistic particles moving out from the pole would, because of the curvature of the field line, radiate a narrow beam in the direction of the instantaneous particle velocity, this radiation being largely polarized in the plane containing the field line. Coherent processes are necessary to account for the intensities observed. Pacini and Rees[12] suggest that if the emission is originating close to the surface of the star then protons and not electrons must be responsible.

It has been shown[10] that differential Faraday rotation is not responsible for the variation in position angle across the pulse in PSR 0833−45. Morris *et al.*[5] have observed PSR 2045−16 at a frequency of 2650 MHz and found a similar variation in position angle to that shown in Fig. 1*d*. Combination of these two observations yields a value of $0{\cdot}10 \pm 0{\cdot}23$ rad/m^2 for the differential rotation measure between the leading and trailing peaks of the pulse. Any such differential rotation between parts of a pulse must take place within the velocity of light cylinder. Current models[13] indicate that gyrofrequencies are greater than, or of the order of, the frequency of radio emission within the velocity of light cylinder, so Faraday rotation in the usual sense would not be expected there.

It has been pointed out[5] that the position angle variation observed for PSR 2045−16 (Fig. 1*d*) is that expected when the line of sight passes very close to the magnetic pole. It is proposed that for PSR 1237+25 (Fig. 1*b*) the line of sight passes directly through the pole, the position of which coincides with the dip in the polarized component at the centre of the pulse. In this case no swing of position angle would be expected. There is some indication that the pulse profile complexity is correlated with separation of the line of sight from the magnetic pole, those cases where the separation is small having complex (many component) pulses.

The continuous variation of position angle through the pulse, even when the pulse profile is complex, combined with the absence of differential Faraday rotation, gives strong support to the model of pulsar emission proposed by Radhakrishnan and Cooke and by Komesaroff. It would appear impossible, from symmetry considerations, to account for these observations by models in which the double pulse structure originates in a dual lobe radiation pattern from a single particle beam[9,14]. Also, the high fractional polarizations observed for these slower pulsars do not appear consistent with the plasma turbulence model proposed by Ichimaru[15].

The observation that the peaks in the pulse profile have a smaller percentage polarization than the weaker regions is simply explained if the peaks of emission are radiation from particles of higher energy than those responsible for the rest of the pulse. Provided the frequency of observation is below the synchrotron critical frequency, the emission intensity is increased and the fractional polarization is reduced as the particle energy is increased. Multiple component pulses as observed for PSR 1237+25 and PSR 2045−16 (Figs. 1*b* and 1*d*) can then be accounted for as radiation from several different beams, whereas they are more difficult to explain in the Fresnel zone model[11]. Also, observed pulse widths are considerably larger than those predicted by the Fresnel zone argument, so it would seem that other factors must also be important.

Finally, it is pointed out that the high percentage polarizations observed make it essential to consider the total intensity rather than one linear component when discussing pulse shapes and amplitudes, spectra of pulse components, or related topics.

I thank those members of the staff of the National Radio Astronomy Observatory, particularly W. D. Brundage, who assisted with the observations, and W. L. Peters for assistance in preparing the figures.

The National Radio Astronomy Observatory is operated by Associated Universities, Inc., under contract with the US National Science Foundation.

Unidentified Interstellar Microwave Line

DURING a search for $H^{12}C^{14}N$ (hydrogen cyanide) and its molecular isotope $H^{13}C^{14}N$, we have detected a new molecular line. The discovery was made in June 1970 using the 36-foot telescope of the National Radio Astronomy Observatory in Tucson, Arizona. The receiver was a 3-mm mixer radiometer developed by NRAO in conjunction with Jefferts, Wilson and Penzias of the Bell Telephone Laboratories. The single sideband noise temperature of the radiometer was 3000 K and it covered frequencies from 85 to 90 GHz. At these frequencies the telescope has a beamwidth of 1′ of arc and a beam efficiency of 50 per cent under optimum conditions. The filter bank receiver used consisted of forty filters spaced 1 MHz apart covering a velocity range of 130 km s^{-1}.

The calibration of the antenna beam efficiency was accomplished by making observations of Jupiter. The observations were made during June when daytime heating caused some variation in the gain of the antenna. This gain variation is primarily due to a broadening of the main beam. For those molecular clouds which are several minutes of arc in diameter, the effect of the variation in gain on observed antenna temperature should be small. The accuracy of the antenna temperature measurements is estimated to be ±30 per cent. Because of its proximity to the Sun, Orion had to be observed with the dome closed which attenuates the observed antenna temperatures by approximately a factor of two. Antenna temperatures given here are referred to a calibrated noise tube and are an average of several observations. This should smooth out the gain variations; it underestimates the actual antenna temperature, however. No correction was made for dome attenuation in the case of Orion.

As we are unable to make a positive spectral identification of this new line we shall refer to it as the X-ogen line (which means that it has an unknown extraterrestrial origin). The line appeared in the upper sideband of the receiver during a period when the local oscillator was tuned to receive the $H^{13}C^{14}N$ line at 86·3 GHz in the lower sideband. After determining the line frequency, the local oscillator frequency was increased in order to place the line in the lower sideband of the receiver. The line appeared again in the expected channels of the filter bank receiver. Comparison measurements were made off source to remove unbalance in the filter receiver and to check for interference. Additional baseline smoothing was accomplished by frequency-switching the receiver. As the X-ogen line was found in the sources in which the $H^{12}C^{14}N$ line appeared, the radiometer was checked for spurious responses. All responses were at least 30 dB (1/1,000) below the principal sidebands of the receiver, however.

In determining the rest frequency of the X-ogen line, comparisons were made with HCN and CO observations (Table 1). A comparison of velocities for several molecules and atoms in various interstellar clouds can be found elsewhere[1]. In a given source, the cloud velocity can be obtained from data on these molecules. The velocity can then be used to shift the observed X-ogen frequency back to obtain the corresponding rest frequency. There is a certain amount of discrepancy between velocities measured with different molecules, probably due to some degree to the different regions within a given cloud which are involved in absorption or emission from a particular molecule. The main source of error in our technique is probably due to the three unresolved HCN quadrupole components which may introduce a systematic error in the profile comparisons. As a result, the accuracy to which the X-ogen rest frequency can be determined is limited to ±2 MHz.

The frequency determined for the X-ogen line is 89·190±0·002 GHz which is 560 MHz higher than the $H^{12}C^{14}N$ (1→0) transition. In a limited survey of molecular clouds, X-ogen was found in Orion, W51, W3 (OH), L134 and in Sgr A (NH_3A), the NH_3 cloud located 3′ south of Sagittarius A (ref. 2). The spectra for the five sources are shown in Fig. 1 and the spectral parameters are listed in Table 1. The width of the line in Orion and several other sources is less than the corresponding line in $H^{12}C^{14}N$. The velocity agreement with $H^{12}C^{14}N$ and other molecules was generally within 7 km s^{-1}. In Sagittarius the line is very broad, extending from 0 km s^{-1} to +50 km s^{-1}. A similar broad feature is seen in $H^{12}C^{14}N$, $H_2{}^{13}C^{16}O$ and other interstellar molecular spectra.

It is unlikely that X-ogen is an atomic line because the only nearby atomic recombination line of any significance is H 59α at 89·199 GHz (ref. 3). In addition to the frequency discrepancy, H 59α would not be expected to have the intensity and sharp profile of the X-ogen line. X-ogen cannot be explained by Doppler-shifted $H^{12}C^{14}N$ because a velocity offset from the local standard of rest of 1,690 km s^{-1} would be required, highly improbable for a galactic gas cloud. We rule out transitions of any rare isotope of hydrogen cyanide because there are no known isotopic transitions at the X-ogen frequency. Finally, we do not believe that X-ogen is a "hot band" rotational

transition of HCN because of the excitation energy required (the lowest vibrational state is ν_2 at 569 cm^{-1}). To add to the identification problem, it is possible that we have not detected the main molecular isotope of X-ogen but a less common member instead.

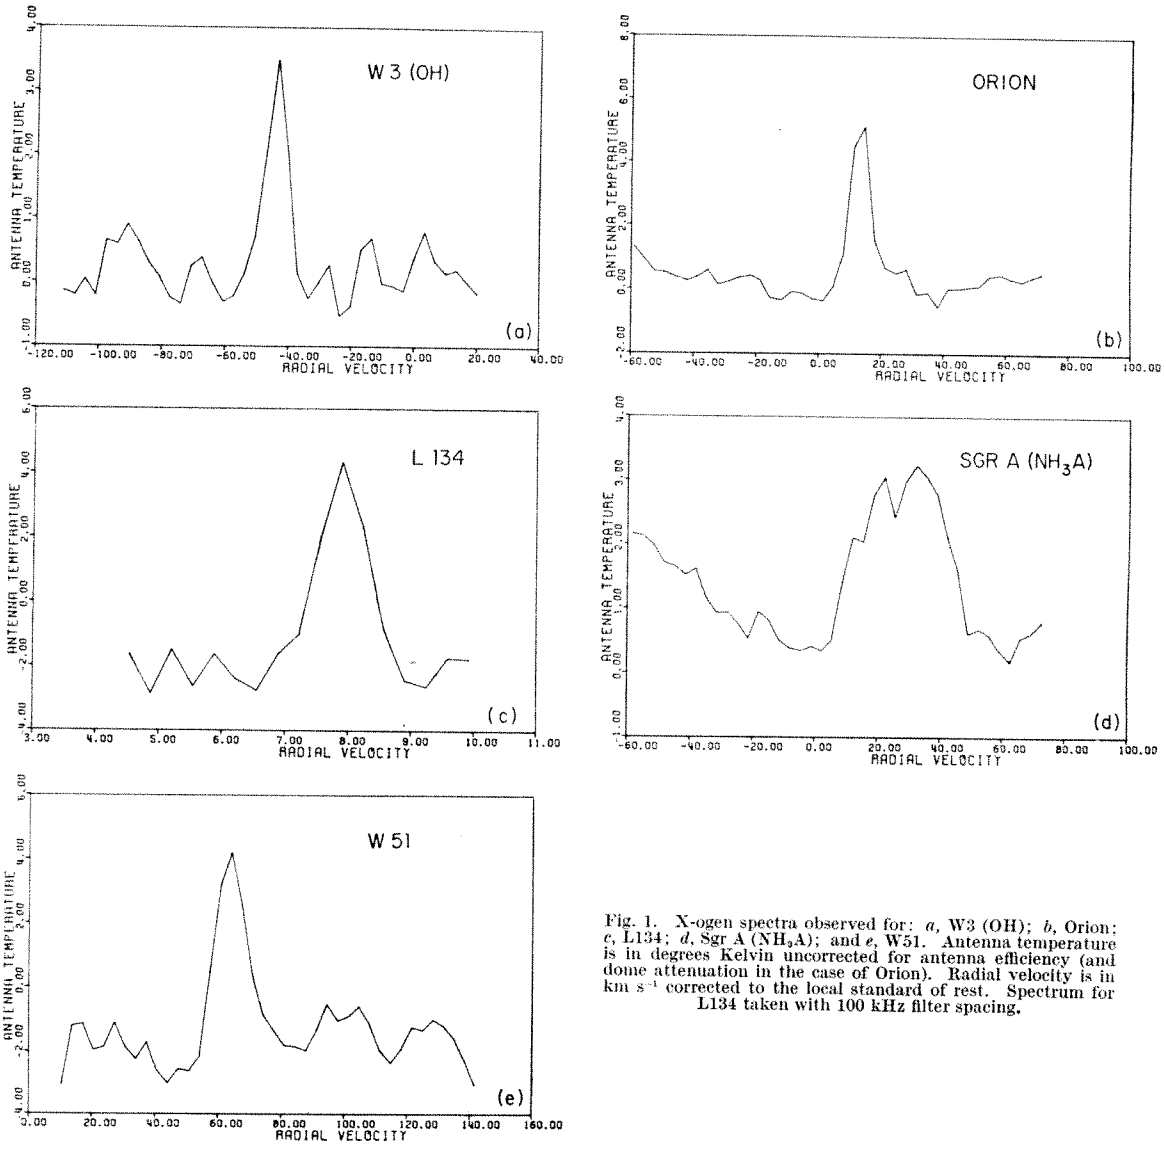

Fig. 1. X-ogen spectra observed for: *a*, W3 (OH); *b*, Orion; *c*, L134; *d*, Sgr A (NH_3A); and *e*, W51. Antenna temperature is in degrees Kelvin uncorrected for antenna efficiency (and dome attenuation in the case of Orion). Radial velocity is in km s^{-1} corrected to the local standard of rest. Spectrum for L134 taken with 100 kHz filter spacing.

Several molecules have been suggested which have transitions in the neighbourhood of 89,190 MHz. For example, the 7_{16}–6_{43} transition frequency of $H_2{}^{32}S$ is calculated to be 89,500 ± 300 MHz from infrared ground state combination differences (unpublished results of L. E. S.). The line strength for this transition is small, however, and the two levels involved require rotational energy of approximately 360 cm^{-1}; hence this H_2S transition would have to be undergoing maser action in order to be detected. From our present data the X-ogen emission seems to be fairly normal which tends to rule out H_2S as a possible identification. HNC (hydrogen isocyanide), an isomer of hydrogen cyanide, has been suggested by G. Herzberg as a possible identification because HCN and X-ogen are often found in the same cloud (see Table 1) and the X-ogen frequency is only 560 MHz higher than the $J = 1 - 0$ transition frequency of $H^{12}C^{14}N$. An *ab initio* calculation based on current knowledge of the HNC molecular geometry[4] places the $J = 1 - 0$ transition of $H^{14}N^{12}C$ in excess of 2 GHz above the X-ogen frequency and the corresponding transition of $H^{14}N^{13}C$ more than 1 GHz below. We cannot rule out HNC on this basis, however, because the structural information is somewhat imprecise for an accurate microwave calculation. Klemperer[5] has suggested the molecular ion $H^{12}C^{16}O^+$ and calculated the $J = 1 - 0$ transition frequency to be 89,246 MHz which is only 55 MHz above the X-ogen frequency. There is no apparent identification conflict with HCO because its nearest transition is expected to fall approximately 2·4 GHz below the X-ogen line.

Higher resolution spectra are needed to aid in the identification of X-ogen. Our present resolution and signal-to-noise ratio are not adequate to detect hyperfine splitting or similar spectral structure. Profile-matching of high resolution X-ogen spectra with CO spectra[6] should remove the possible systematic error in the rest frequency introduced by using HCN spectra. Mapping is necessary to learn the spatial extent of the X-ogen emission from each source and to check for anomalous emission.

We thank E. K. Conklin and G. Grove for help with the observations, and N. P. Albaugh, S. Weinreb and J. Edrich for their efforts in the construction of the receiver.

Absorption Lines in Quasi-stellar Objects with $z_{abs} > z_{em}$

OF the approximately twenty-five quasi-stellar objects which are known to have absorption lines[1,2], six have absorption lines with larger redshifts than the corresponding emission lines. In each case, $0{\cdot}01 \lesssim z_{abs} - z_{em} < 0{\cdot}03$. Four of the objects (PKS 1229−02, PHL 1222, PKS 0119−04, 4C 25·5) have only one emission line and one absorption line system. The two remaining objects (Ton 1530, B 194) each have one emission line system, but several distinct absorption line systems, only one of which has a larger redshift than the emission lines. It has been suggested that absorption lines in QSOs originate in clouds of gas which have been ejected from the QSO as a result of outbursts[3]. The lines having $z_{abs} > z_{em}$ are then interpreted as resulting from clouds which have a peculiar inward velocity that exceeds the mean outward motion of the system of clouds. In spite of the extremely large velocity dispersion required among the clouds to bring about this situation, it is conceivable that it might occasionally occur. But the relatively common occurrence of lines for which $z_{abs} > z_{em}$ suggests that the assumption that the usual state of a QSO is one in which matter is flowing outward may not be entirely valid.

It has been emphasized by Burbidge and Burbidge[1] that most of the absorption line redshifts in QSOs have $|z_{em} - z_{abs}| < 0{\cdot}03$. This has been interpreted to mean that the absorbing gas is closely associated with the QSOs. This interpretation is substantiated by the fact that most of the line profiles for which $0 < z_{em} - z_{abs} < 0{\cdot}03$ resemble the classical P Cygni-type profiles[4,5]. That is, these lines can be understood in terms of the scattering of resonance line radiation in an expanding medium with spherical symmetry. By extending this reasoning to the situation where $z_{abs} > z_{em}$, the most plausible explanation for such lines is that they are formed by gas which is moving toward the QSO. Because the absorption component of the lines is in all cases less intense than the adjacent continuum, it must be caused by gas which lies between the observer and the continuum source, which I assume to be located at the centre of the QSO and to have dimensions $< \sim 10^{16}$ cm (as indicated by the time scale of the variability of the continua of QSOs). Consequently, as long as the emission component of the lines is only broadened, and not redshifted, by the motion of the infalling gas, the difference $z_{abs} - z_{em}$ is a measure of the radial velocity of gas. Because $z_{abs} - z_{em} \sim 0{\cdot}02$ typically, then $v \sim 0{\cdot}02c$, directed inward.

Rees[3] has mentioned the alternative hypothesis that $z_{abs} > z_{em}$ may be caused by the transverse Doppler effect. For this to produce the observed redshift differences, the space velocities of the clouds must exceed $0{\cdot}1c$. Six QSOs indicate material velocities this large, while six objects have $z_{abs} > z_{em}$. Yet, if the transverse Doppler effect were indeed important, the number of objects for which $v > 0{\cdot}1c$ should be much greater than the number for which $z_{abs} > z_{em}$. I shall assume, therefore, that the non-zero redshift differences are true indicators of the radial velocities of the absorbing clouds.

What could cause these high inward velocities? It is doubtful whether any explosion or ejection phenomenon would directly accelerate the gas inward. The centres of activity in such objects are usually associated with the central regions, toward which the gas is falling. As indicated previously, cloud–cloud collisions may set up a velocity dispersion in gas which is being ejected from a QSO at high velocities such that occasional clouds have negative radial velocity with respect to the QSO. One would then expect, however, to observe $z_{em} > z_{abs}$ much more frequently than $z_{abs} > z_{em}$, but this is contrary to the observations. I propose that the high inward velocities are caused by the acceleration of gas due to the gravitational attraction of a large central mass. This basic idea has already been proposed in a different context by Lynden-Bell[6] for the nuclei of galaxies. He has considered this problem in some detail, so I shall not pursue the matter further. I am interested here, not in attempting to explain the general QSO phenomenon but in suggesting that absorption lines with redshifts larger than the emission lines may be a manifestation of the infall of substantial amounts of gas due to gravity.

If this interpretation is correct, a lower limit to the mass of a QSO can be obtained. Let us assume that clouds of gas, having angular momentum per unit mass h, are falling toward the central mass from essentially infinity. Ignoring the possible effects of cloud–cloud collisions, the angular momentum of the gas limits the velocity that the clouds may attain by preventing any approach to the centre closer than $r_{min} \sim h^2/2G\mathcal{M}$, where $\mathcal{M}$ is the central mass of the QSO. The equation of motion for the gas is $\dot{v}_r = -G\mathcal{M}/r^2$, from which it can be shown that $v^2 \sim 2G\mathcal{M}/r$. Except near the region where $r \sim r_{min}$, the space velocity v may be equated with the radial velocity, v_r, of the gas. Unless the injection of gas into the potential well of the central object occurs rather evenly in time, the profile of the absorption lines should reflect the changing velocity of the gas as it is accelerated. The time scale τ over which any portion of the gas has a characteristic velocity v, that is, over which the gas does not change its velocity by a factor of ~ 2, may be taken to be given by $\tau \sim v/2|\dot{v}| = 2G\mathcal{M}/v^3$. That is, for the velocity to remain unchanged over a longer time scale, one is restricted to flatter portions of the potential well; greater distances, in other words. Thus a given velocity remains unchanged over a longer period of time only for a larger mass. Now, it appears from the visual inspection of the spectra of at least one of the QSOs, Ton 1530, that no changes in the absorption lines have been detected over a period of several years (R. Lynds, private communication). For gas which has been accelerated to velocities of $0{\cdot}01c$, this lack of variability can be produced only by a central mass having $\mathcal{M} \gtrsim 10^7\ \mathcal{M}_\odot$. The corresponding minimum distance to which the gas has fallen is $r > 2 \times 10^{16}$ cm. These limits can be raised by more than an order of magnitude for objects with $z_{abs} - z_{em} \sim 0{\cdot}03$, like B 194 and PHL 1222, if they are observed to have undergone no variability since the first epoch plates were taken of these objects.

The absorption lines in QSOs for which $z_{abs} > z_{em}$ should be studied carefully to detect possible changes in

either linewidth or redshift with time, because the time-scale of such variations may lead to masses for the QSOs. This reasoning probably cannot be applied to objects for which $z_{em} > z_{abs}$ because the absorbing gas in these QSOs is moving outward, and therefore the likelihood that such gas is moving only under the influence of gravity is much less than in the opposite situation. The fact that Ton 1530 and B 194 have absorption redshifts for which both $z_{abs} > z_{em}$ and $z_{abs} < z_{em}$ indicates that the infall and outflow of material may be a continuing cycle. This suggests an evolution for the gas associated with QSOs in which it is accreted by gravitation, and then expelled by some mechanism such as particle pressure[7].

If the interpretation of the $z_{abs} > z_{em}$ phenomenon is correct, the need to postulate the creation of matter in the centre of QSOs[8] would be alleviated somewhat, because it would attest to both the influx of large quantities of gas toward the central regions and the existence of sufficiently large central masses to satisfy the energy requirements of the QSOs.

I thank Drs T. Kinman, D. Layzer, R. Lynds and R. Weymann for helpful discussions.

Hoyle–Narlikar Theory of Gravitation

HARRIS[1] has given a treatment of the Bohr quantization of a spherically symmetric mass distribution surrounded by a gravitational field in the Einstein theory. One result is to provide a relationship between cosmological and elementary particle parameters.

This note concerns the Bohr quantization of the gravitational theory of Hoyle and Narlikar[2]. This theory derives from a direct interparticle action

$$S = \sum_{a<b}\sum \iint \tilde{G}(A,B)\mathrm{d}a\,\mathrm{d}b \qquad (1)$$

summed once over all pairs of particles a,b, $\mathrm{d}a\mathrm{d}b$ are world line elements and $\tilde{G}$ is a time-symmetric scalar two-point Green function satisfying the equation

$$g^{ij}\,\tilde{G}(X,A)_{;ij} + \tfrac{1}{6}R(X)\tilde{G}(X,A) = -(-g)^{-\frac{1}{2}}\,\delta^4(X,A) \qquad (2)$$

where R is the scalar curvature and g the determinant of g^{ij}.

The theory is Machian in the sense that the equations of motion do not exist in the limit of a one particle universe. We cannot therefore consider the single mass case of Harris, but must account for all masses $b \neq a$ in the universe. The mass of particle a is given by

$$m_a(X) = -\sum_{b\neq a}\int \tilde{G}(X,B)\mathrm{d}b \qquad (3)$$

and is a function of position.

Although the theory is nonlinear, so that the contributions from the right-hand side of equation (3) may not be superposed directly, such a treatment of Machian theories is often given as an approximation and has been discussed in this case by Hawking[3]. Although the advanced contribution to m_a diverges in this approximation, the retarded contribution is finite, and given by

$$m_a = N/H^2 \qquad (4)$$

where H is the Hubble constant and, in the steady-state cosmology, N is the constant particle density

$$N(X) = \sum_a \int \delta^4(X,A)[-g(X,A)]^{-\frac{1}{2}}\,\mathrm{d}a \qquad (5)$$

If we assume that in a rigorous treatment of the Hoyle–Narlikar gravitation theory the advanced contribution causes no embarrassment we may therefore proceed with the fully retarded part (4). Remembering that this is only a linear approximation, we substitute (3) and (4) into the total action (1)

$$S = \frac{N}{H^2}\sum_a \int \mathrm{d}a \qquad (6)$$

If we work with the conformally flat form of the cosmological metric, it is easily shown[3] that the right-hand side of (6) may be written

$$\frac{N^2}{H^2}\int_0^{1/H}\int_{-\infty}^{-1/H}\frac{4\pi r^2\,\mathrm{d}r}{(\tau H)^4}\,\mathrm{d}\tau$$

where (5) has also been used. This is immediately evaluated to give

$$\frac{N^2}{3H^3}\cdot\frac{4\pi}{3}\left(\frac{1}{H}\right) = \frac{N_0^2}{4\pi}$$

where N_0 is the total number of particles in the universe. The net action for each particle is then Bohr quantized

$$N_0/4\pi = nh \qquad (7)$$

Substituting this into (4) for the mass

$$m_a = 3nhH \qquad (8)$$

We now have to decide on the value of n. If the theory is Machian we expect $m_a \to 0$ as $N_0 \to 0$ so that n should be a positive power of N_0. We make the *ad hoc* assumption that n is an integer multiple of $\sqrt{N_0}$. This quantity is the mean fluctuation in the total number of particles, N_0, and frequently appears in this type of analysis, although as yet its significance is not understood.

Then

$$m_a = 3n_0\sqrt{N_0}\,hH = 3n_0\sqrt{N_0}\,hH/c^2$$

in e.g.s. units, where n_0 is a smaller integer.

Numerically this gives

$$m_a \sim 10^{-24}\ \mathrm{g}$$

or about the mass of elementary particles. This result becomes still more striking if we use the well known "coincidence"

$$\sqrt{N_0} \sim \frac{c/H}{4\pi e^2/m_e c^2}$$

(m_e = mass of electron). Then

$$m_a \sim \tfrac{1}{2}\frac{\hbar c}{e^2}\,n_0\,m_e$$

$$\sim \tfrac{1}{2}\times 137\,n_0\,m_e$$

which is just Nambu's formula[4], originally derived on empirical grounds to describe the mass spectrum of elementary particles.

Energy Levels and Lorentz Invariance

An atom is in an excited state S′ with energy E'. It falls to a state S with lower energy E and emits a photon with frequency ν. According to a basic postulate of quantum mechanics, this frequency is related to the energies by

$$h\nu = E' - E \tag{1}$$

The theoretical calculation of E and E' is carried out in the rest-frame of the atom, and so it would appear that ν in equation (1) is the frequency observed in that frame. Conservation of momentum, however, demands that the atom recoils when the photon is emitted, and so there is not one rest-frame but two—the rest-frame of S′ and the rest-frame of S. It is true that the recoil is small and consequently the two rest-frames are nearly the same. But in spectroscopy wavelengths are sometimes given with 8-figure accuracy, and it is interesting to inquire whether such (or higher) accuracy is consistent with neglect of the small difference between the two rest-frames.

To discuss the recoil relativistically we must speak of 4-momentum, and it is convenient to take units for which $c = 1$ and to use imaginary time ($x_4 = it$). Latin suffixes range 1, 2, 3, 4. Let p'_r, p_r be the 4-momenta of the atom in the states S′, S, and let k_r be the 4-momentum of the emitted photon. Then

$$p'_r p'_r = -m'^2,\ p_r p_r = -m^2,\ k_r k_r = 0 \tag{2}$$

where m', m are the proper masses of S′, S. (Because $c = 1$, proper mass and proper energy are merely different names for the same thing.) Conservation of momentum and energy demands that

$$p'_r = p_r + k_r \tag{3}$$

or equivalently

$$p_r = p'_r - k_r \tag{4}$$

Squaring this and using equation (2), we get

$$m^2 = m'^2 + 2p'_r k_r \tag{5}$$

The frequency ν of the emitted photon is given by $ih\nu = k_4$, the fourth component of a 4-vector, and, if we are to make a significant spectroscopic prediction about this frequency, we must make up our minds what frame of reference to use. If we were concerned with the excitation of an atom (S→S′), it would be natural to use the rest-frame of S. But we are concerned with emission, and there can be no doubt that the rest-frame of S′ is the one to use—it is the mass-centre frame for the event. In this frame we have

$$p'_r = (0,\ 0,\ 0,\ im'),\ p'_r k_r = -m'h\nu \tag{6}$$

and so equation (5) gives

$$h\nu = \tfrac{1}{2}(m'^2 - m^2)/m' \tag{7}$$

If we knew the proper masses, m', m, we could calculate (without reference to equation (1)) the frequency ν, measured in the rest-frame of the atom before emission.

We have now before us two formulae for the frequency of the emitted photon, the formula (1) which will be found in any textbook on quantum mechanics[1] and the formula (7) obtained as above by a simple application of the conservation of 4-momentum, the only quantum feature being the assumption that the energy of a photon is $h\nu$. They cannot both be right, unless the two right-hand sides happened to be equal. That can hardly be the case, but they are nearly equal in practice. This near-equality has been fortunate, for it has permitted quantum theory to grow from strength to strength on the basis of a formula which, to a relativist, cannot but appear rather grotesque. I propose to compare the two formulae, that is, the formulas (7) and (1), rewritten as

$$h\nu_0 = E' - E \tag{8}$$

to avoid using the same symbol for different things. I shall call ν the true frequency and ν_0 the conventional frequency; E' and E are energy levels of the atom, calculated by quantum theory.

No comparison can be made until we answer the following basic question: What is the proper mass (equivalently, rest-mass or rest-energy) of an atom in a state S with energy E?

It appears that if $m_1, m_2, \ldots m_n$ are the proper masses of the particles of which the atom is composed, then the proper mass m of the atom is

$$m = M + W \tag{9}$$

where

$$M = m_1 + m_2 + m \ \ldots \ + m_n \tag{10}$$

and W is the (negative) binding energy or mass defect[2]. But equation (9) as it stands does not mean much. It might be taken as the definition of W, and the fact that W is negative merely implies that the mass of the atom is less than the sum of the masses of its constituent particles. In fact, equation (9) becomes significant only when we identify W with the energy E as in equation (8) and write for the two proper masses in equation (7).

$$m' = M + E',\ m = M + E \tag{11}$$

I have searched without success for an authoritative statement that $W = E$. Perhaps it is accepted without question (see ref. 3). These authors use equation (8) above without mention of the two frames of reference, but the difference between them may be covered by the approximation used.

Substitution from equation (11) in equation (7) gives

$$h\nu = (E' - E)[M + \tfrac{1}{2}(E + E')](M + E')^{-1} \tag{12}$$

and so by equation (8) the ratio of the true frequency to the conventional frequency is given accurately by

$$\nu/\nu_0 = [1 + \tfrac{1}{2}(E + E')/M](1 + E'/M)^{-1} \tag{13}$$

Now E/M and E'/M are in fact dimensionless small quantities of the same order of magnitude, and expansion of equation (13) gives

$$(\nu_0 - \nu)/\nu_0 = \tfrac{1}{2}(E' - E)/M + \mathrm{O}[(E/M)^2] \tag{14}$$

or, with equation (8)

$$(\nu_0 - \nu)/\nu_0 = \tfrac{1}{2}h\nu_0/M + \mathrm{O}[(h\nu_0/M)^2] \tag{15}$$

This may be called the fractional error arising from the use of the conventional frequency instead of the true frequency.

To appreciate the magnitudes involved, let us restore c and use c.g.s. units, so that

$$(\nu_0 - \nu)/\nu_0 = K + \mathrm{O}(K^2) \tag{16}$$

where

$$K = \frac{h\nu_0}{2Mc^2} = \frac{h}{2cM\lambda} \tag{17}$$

λ being the wavelength of the emitted photon, measured in the rest-frame of the atom before emission.

Consider in particular the spectrum of hydrogen. Because K is small, it is not necessary to carry many decimal places. In c.g.s. units we have

$$h = 6{\cdot}62 \times 10^{-27},\ c = 3{\cdot}00 \times 10^{10}$$
$$M = 1{\cdot}67 \times 10^{-24},\ \lambda = 6{\cdot}56 \times 10^{-5} \qquad (18)$$

this last being the most prominent line in the H-spectrum. Hence, because the last term in equation (16) is of the order 10^{-18}, the fractional error is

$$(\nu_0 - \nu)/\nu_0 = 1{\cdot}01 \times 10^{-9} \qquad (19)$$

Thus we may conclude that, in general terms, the error does not make itself manifest if we are satisfied with 8-figure accuracy in spectroscopy, but does appear in the ninth figure, at least in the case just considered.

I was led to consider the above matters in an attempt to review arguments by which one sets an upper bound to the proper mass of a photon. If μ is that proper mass, we are to modify the last of equation (2) to read $k_r k_r = -\mu^2$ and then proceed much as above with this modification. But I decided that it would confuse the issue to try to discuss two things at once, and so I have followed the usual hypothesis—the proper mass of a photon is zero—in order to bring out the relativistic inadequacy of the commonly accepted formula (1).

Because proper mass (equivalently, rest-mass, proper energy, or rest-energy) is the most important Lorentz-invariant scalar associated with any system, no relativist can feel happy about the formulae (11). They are patched up. The conservation equations (3) or (4) are very fundamental, and manipulation of those equations suggests that the basic scalar is not proper mass, but its square—in fact, that $m = M + E$ is merely a useful approximation to some more fundamental formula for m^2. Indeed, according to the covariant Bethe–Salpeter wave equation[4] it is m^2 that is to be quantized. But even that equation offends what may be called "Minkowskian aesthetics" in the matter of the "reduced mass" factors; in Minkowskian geometry one does not expect to see in any vital formula the sum of the magnitudes of 4-vectors $(m_1 + m_2)$, any more than one expects to find, in Newtonian mechanics, the sum of the magnitudes of two forces or of two momenta.

I thank colleagues for valuable discussions.

Transformation to Rotating Coordinates

In the treatment of problems involving rotating coordinate frames one of two types of viewpoint is conventionally adopted. The assumption may either be made that the use of principles familiar in special relativity can be extended to the rotating coordinate case, or a general-relativistic treatment may be used, with use of an explicit coordinate transformation for uniform rotation in going from the inertial frame to the rotating frame.

The first approach leads to a "paradox" initially cited by Ehrenfest[1]. In this viewpoint, illustrated by the model of the rotating disk, distances in the radial direction are assumed to be unaffected by the rotary motion, for these are everywhere orthogonal to the direction of motion. Measuring scales used for circumferential measurements are assumed to be Lorentz-contracted by a factor $(1 - \omega^2 r^2/c^2)^{1/2}$, where ω is the angular velocity and r the radius, because such measurements are everywhere locally parallel to the direction of motion. This leads to the usual conclusion that an observer on the disk would find a circumferential measurement of $2\pi r(1 - \omega^2 r^2/c^2)^{-1/2} > 2\pi r$. This conclusion has since been adopted by many authors as a demonstration of non-Euclidean character of the geometry in non-internal coordinate frames[2–6].

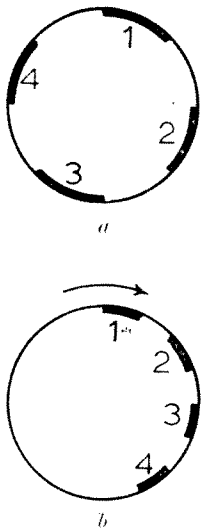

Fig. 1. *a*, Stationary disk; *b*, result of an arbitrary application of Lorentz contraction to periphery of disk in rotation.

The fallacy in the foregoing argument can be readily seen from the following example. Consider a circular disk, made possibly of transparent material, on the circumference of which a pattern of stripes is painted in four octants, as indicated in Fig. 1*a*. The disk is then set into rotation at a speed such that the rim is travelling at 86·6 per cent of the velocity of light in free space, for a Lorentz contraction factor of 1/2. The positions of the ends of the stripes on the rim can be observed at an instant of laboratory time. This is possible by means of a flash of light emitted above the plane of the disk which exposes the shadow of the stripes on a photographic film held stationary in the back of the disk; an alternative coincidence-detection observation may also be devised. An elementary application of the special-relativistic hypothesis could then lead to the expectation of a pattern as in Fig. 1*b*, which is clearly impossible on the basis of the symmetry of the disk. The special-relativistic assumption must therefore be discarded.

In deriving the equations of the electromagnetic field in a rotating reference frame, Schiff[7] used the explicit transformation to rotating coordinates

$$x = x_0 \cos \omega t_0 + y_0 \sin \omega t_0$$
$$y = -y_0 \sin \omega t_0 + y_0 \cos \omega t_0$$
$$z = z_0 \qquad (1)$$
$$t = t_0$$

The metric tensor of this transformation was used to obtain the current and charge-containing field equations from the covariant form

$$\frac{\partial}{\partial x^i}[\sqrt{-g}\, g^{im}\, g^{jn}\, F_{mn}] = \sqrt{-g}\, J^j \qquad (2)$$

The field equations which Schiff obtained were placed into standard vector notation in the coordinates of the rotating frame by Webster[8], who found

$$\nabla \cdot B = 0$$

$$\nabla \times E = -\dot{B}$$

$$\nabla \cdot E = \rho/\epsilon_0 + \nabla \cdot (v \times B)$$

$$\nabla \times B = \mu_0 J + \frac{1}{c^2}\dot{E} - \frac{1}{c^2}\{\nabla \times [v \times (E - v \times B)] + v \times (\nabla \times E)\} \quad (3)$$

where $v = r\omega$ and the equations are written in MKS units.

Equations (3) correctly approach the standard inertial-frame form of Maxwell's equations for $v \to 0$, but they may be expected to be incorrect for nonvanishing v. This expectation is based on the essentially Galilean character of the transformation equation (1). This Galilean character was inferred from the result of the following procedure: the Schiff–Webster calculation was carried out, but with the use of the classical Galilean transformation for rectilinear motion

$$\begin{aligned} x &= x_0 + vt_0 \\ y &= y_0 \\ z &= z_0 \\ t &= t_0 \end{aligned} \quad (4)$$

When the electromagnetic field equations were obtained in the Galilean frame represented by this transformation, and were placed into vector notation, the resulting equations were identical with equation (3). The rectilinear Galilean transformation was discarded by Einstein[9] in favour of the special-relativistic (Lorentz) transformation to a uniformly moving frame. This change was induced as a consequence of the experimental observation, by Michelson and Morley and others, of the isotropic constant velocity of light in inertial frames.

Measurements of the anisotropy of the velocity of light are capable in principle of verifying the correctness of the coordinate transformation to rotating coordinates, through the avenue of the metric tensor g_{ij}, which depends on the coordinate transformation law according to

$$g_{ij} = \frac{\partial x^a}{\partial x^i}\frac{\partial x^a}{\partial x^j} \quad (5)$$

For light propagating in the direction specified by the direction cosines n^i, the measured velocity of light will be[10]

$$v^i = \frac{-cg_{44}}{n^i g_{14} + (-g_{44})^{1/2}} \quad (6)$$

With measurements of sufficient accuracy, the correctness of a rotating-coordinate transformation can be verified by the use of equation (6), or equivalently by solution of the equation for the null-element of world line $ds^2 = 0$ for the propagation of light. The experimental configuration for such measurements of the velocity of light may take many forms and hence will not be discussed here. It is sufficient, however, that the experiments are possible in principle. Until the results of such measurements are available, we must recognize that we do not have a verified form for the law of transformation to rotating coordinates.

Denudation of the Continents

Estimates of denudation often enter into geologic argument and have to be extrapolated backwards over geological intervals of time. The importance of human activity in the present-day erosional cycle has been pointed out by Douglas[1] and has been carefully evaluated by Judson[2] in a comparison of world-wide river load estimates with data from the nearly undisturbed Congo and Amazon basins. Judson concludes that man's intervention has increased the overall denudation rate from 9 to 24 billion tons a year: far more than enough to discredit the present rate as a geologic parameter. In this communication I attempt to verify Judson's pre-human estimate and to defend its general applicability to the past 300 million years.

Compared with man's erosion of the soil his effect on weathering has probably been small. The present rate of chemical weathering (indicated by the dissolved load of rivers) should therefore be about the same as it was when the soil was conserved and weathering roughly balanced denudation. A convenient index of chemical weathering is sodium, a widespread, mobile and fairly abundant element the distribution of which is reasonably well known. The pre-human denudation rate can then be calculated

$$\text{denudation rate} = \frac{\text{transport rate of dissolved sodium in rivers}}{\text{sodium leached from unit mass of source rock}} \quad (1)$$

Geochemical studies[3,4] indicate that the weathering of 100 tons of average continental surface rock supplies about 0·9 ton of sodium to the hydrological cycle; and the annual discharge of dissolved sodium in rivers is about 20×10^7 tons[3,5], of which 9×10^7 tons have been recycled from the sea through the atmosphere[3,4] and $1{\cdot}5 \times 10$ released by human activities[4]. This leaves a net discharge arising from chemical weathering of $9{\cdot}5 \times 10^7$ tons, and substituting in equation (1) we get

$$\text{annual rate of denudation} = \frac{9{\cdot}5 \times 10^7 \times 100}{0{\cdot}9} = 10{\cdot}5 \times 10^9 \text{ tons} \quad (2)$$

Sedimentary rocks decay by erosion and eventually by metamorphism. If, for a given formation, the rate of each process is proportional to s, the amount of sediment present, the decay should follow a law of the form

$$\frac{ds}{dt} = -k.s \quad (3)$$

according to which the surviving volume of a formation of age t would be

$$s = r.e^{-kt} \quad (4)$$

r being the original volume of the formation. If a formation is defined as consisting of the sediments formed in a year, then r represents the annual rate of sedimentation (= denudation). If the surviving volumes of all the sedimentary systems are known the volume of each system can be divided by the duration of the corresponding geological period, and the quotient or "survival rate" can be plotted against the average age of the system[6]. Then, if the points so obtained all lie on a curve $s = r.e^{-kt}$, it may be concluded that the sedimentation rate has

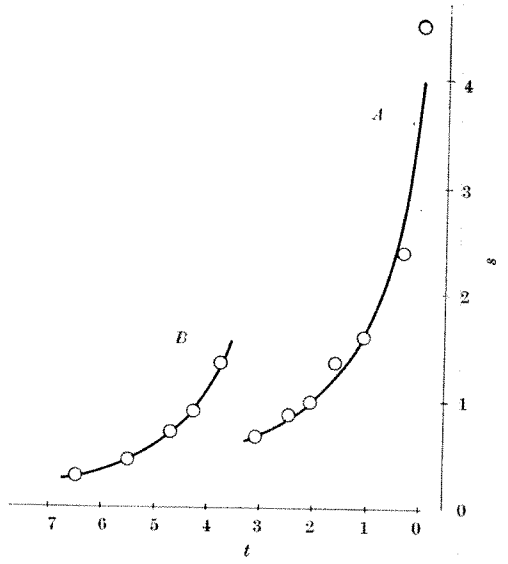

Fig. 1. Survival rate of sediments as a function of their age. s, Surviving volume (now) of each geologic system, expressed in km³ per year of the corresponding period; t, average age in hundreds of millions of years. A, $s = 2{\cdot}1\ (e^{-2{\cdot}0t} + e^{-0{\cdot}37t})$; B, $s = 1{\cdot}4\ (e^{-1{\cdot}7(t-3)} + e^{-0{\cdot}44\ (t-3)})$.

remained constant and it can be found by solving for r. Unfortunately, volume estimates are not common in stratigraphic literature; but enough data are available to make a rough calculation. According to Ronov and Yaroshevsky[7], the total volume of sediments on the continents and shelves is about 600×10^6 km³; this includes detailed estimates by Ronov and Khain[8] totalling 268×10^6 km³ for the Devonian, Carboniferous, Permian, Triassic and Jurassic systems. To get a tentative list of the volumes of all the sedimentary systems, I divided the balance of 332×10^6 km³ between the remaining systems in proportion to their maximum known thicknesses as reported by Holmes[9]. The deep sea sediments, here taken as 100×10^6 km³, were added to the Cretaceous, Tertiary and Pleistocene in proportion to the respective durations of these periods, on the assumption that most of the present ocean floor is post-Jurassic (personal communication from B. C. Heezen) and that it has been spreading at a uniform rate. The resulting volumes are shown in Table 1, and the corresponding survival rates are plotted in Fig. 1 as a function of age.

It seems that the geologic systems are thus divided into two distinct groups, pre-Carboniferous and post-Devonian, each conforming approximately to a decay law of the type predicted, though for reasons that are not clear it turns out to be binomial

$$s = \frac{r}{2}(e^{-at} + e^{bt}) \qquad (5)$$

For Carboniferous to Pleistocene, the best fit is given by

$$s = 2{\cdot}1(e^{-2{\cdot}0t} + e^{-0{\cdot}37t}) \qquad (6)$$

whence $r = 4{\cdot}2$ km³ per year; or, at a density of 2·6, about 11 billion tons. For the pre-Carboniferous group the best fit is

$$s = 1{\cdot}4(e^{-1{\cdot}7(t-3)} + e^{-0{\cdot}44(t-3)}) \qquad (7)$$

It has been suggested that the earlier Palaeozoic systems have been selectively preserved by burial under younger sediments (personal communication from R. M. Garrels). On the other hand, they might be the fossil remnants of an erosional pattern that could be reconstructed and analysed. Thus for the Devonian (now represented by 1·36 km³ per year of Devonian time), substituting in equation (5), the following equation can be written

$$1{\cdot}36 = \frac{v}{2}(e^{-2{\cdot}0 \times 3} + e^{-0{\cdot}37 \times 3}) \qquad (8)$$

where v represents the volume of Devonian sediments (per year of Devonian time) in existence 300 million years ago, assuming the post-Devonian erosional regime to have taken over at that point. The solution is $v = 8{\cdot}3$, and the pre-Carboniferous denudation rate can now be found by solving the equation

$$8{\cdot}3 = \frac{r}{2}(e^{-1{\cdot}7(3{\cdot}75-3{\cdot}00)} + e^{-0{\cdot}44(3{\cdot}75-3{\cdot}00)}) \qquad (9)$$

whence $r = 16{\cdot}6$ km³ per year. The mean value of r found in this way for the five pre-Carboniferous systems is 16·1, corresponding to about 40 billion tons a year: nearly twice the present denudation rate and four times the immediate pre-human one. It is the second term (e^{-bt}) in equation (5) that reflects the early history of these decay processes as seen today; and because its exponents in equations (6) and (7) do not seem to differ markedly in their coefficients, these two pre-Carboniferous models (selective preservation and rapid erosion) can probably not be distinguished by inspection of the curves.

Table 1. VOLUMES AND SURVIVAL RATES OF SEDIMENTARY SYSTEMS

System	Average age[9] (100 m.y.)	Duration (m.y.)	Max. known thickness[9] (km)	Volume acc. to Ronov[8] (10^6 km³)	Share of all continental and shelf sediments (10^6 km³)	Share of deep sea sediments (10^6 km³)	Total volume (10^6 km³)	Survival rate (km³ yr⁻¹)
Pleistocene	0·01	2	1·8	—	7	2	9	4·50
Tertiary	0·36	68	31·5	—	115	50	165	2·40
Cretaceous	1·03	65	15·5	—	56	48	104	1·60
Jurassic	1·58	45	13·3	62	62	—	62	1·38
Triassic	2·03	45	9·1	45	45	—	45	1·00
Permian	2·48	45	5·8	40	40	—	40	0·89
Carboniferous	3·10	80	13·9	53	53	—	53	0·66

Silurian	4·20	40	10·3	—	37	—	37	0·93
Ordovician	4·70	60	12·1	—	44	—	44	0·73
Cambrian	5·50	100	12·1	—	44	—	44	0·44
Late Pre-Cambrian	6·50	100	7·9	—	29	—	29	0·29
					600[7]	100	700	

Table 2. ESTIMATES OF DENUDATION RATE (BILLIONS OF TONS PER YEAR

Basis of estimate	Present	Pre-human (Recent)	Carboniferous to Recent	Pre-Carboniferous
River-gauging[2] (world-wide)	24	—	—	—
River gauging[2] (selected basins)	—	9	—	—
Sodium cycle	—	10	—	—
Survival rate method	—	11	11	40 (?)

The results of these speculations are summarized in Table 2, together with Judson's estimates of present and pre-human denudation rates. There is fair agreement of the three independent pre-human rates, and there is no obvious sign of drastic variations since the Carboniferous. Before then the rate could have been greater by a factor of about 4, possibly on account of the absence of plant cover, but the evidence for this is inconclusive. Reliable measurements of the pre-Devonian and post-Jurassic

systems are needed for more accurate calculations of the erosional cycle in these periods.

I thank R. M. Garrels and F. T. Mackenzie for their interest and encouragement. I also thank W. Nieuwenkamp for the idea of using sodium cycle to measure denudation.

Numidian Flysch: an Oligocene—early Miocene Continental Rise Deposit off the African Platform

THE Numidian Flysch[1–6] is a thick (1,000–3,000 m) alternating deposit of brown shales and highly quartzose coarse sandstones of Oligocene–early Miocene age that occupies the external part of the Riff-Tellian Atlas-Southern Apennines belt in the Southern Mediterranean (Fig. 1). Mineralogical composition, facies pattern and palaeocurrents indicate that this extensive large wedge of grain flow and slump deposits represents former continental rise sediments at the foot of the cratonal slope of the African Platform[7,8].

The northern coeval counterpart of the Numidian is represented by the Kliwa Sandstones[9–12] in the Carpathians (Fig. 1), and possibly by the Maikop Sandstones in Crimea and Caucasus (personal communication from L. R. Contescu). These formations, also representing continental rise-type deposition, derived their quartz fraction[9–11] from the adjacent cratonal slope of the Russian Platform.

The Numidian foldbelt facing Africa, 2,000 km long, can be traced from Gibraltar to the southern part of the Italian Peninsula[8]. In Algeria the cratonal Numidian quartzarenites grade laterally into eugeosynclinal flysch deposits[6]. In Sicily during the Oligocene–early Miocene the tectonically mobile Panormide Cordillera[4,5,13,14] separated the external (southern) Numidian Flysch (miogeosynclinal sequence) from the internal (northern) Reitano greywackes (eugeosynclinal sequence).

The Reitano Flysch (Oligocene–early Miocene) culminates an allochthonous series constituting the principal nappe of Sicily. The Reitano mudstones and turbides[15] overlie a sequence comprising: (1) Argille scagliose (Upper Cretaceous–early Eocene oceanic pelites); and (2) an Eocene–Oligocene Preflysch sometimes containing andesetic[11] greywacke (turbides) derived from a northern active volcanic island arc. During the paroxysmal phase of the Upper Tortonian orogeny[8] this series was transported above the Mesozoic biohermal carbonate rocks of the Panormide Cordillera and above the Numidian Flysch. A subsequent deformation (base of Middle Pliocene ?) subdivided the Numidian Flysch into several thrust sheets[8].

For the past 20 years most workers[1,6] have considered that the metamorphic or crystalline basement of the internal tectonic land (Gignoux's "Tyrrhenides") or the hypothetical Verrucano-type sandstone of the Panormide Cordillera substratum were the sources of the Numidian Flysch[18–20]. This view, however, is incompatible with the observed mineral composition of the Numidian sandstones which in Southern Italy, Sicily and Tunisia are clean, pure quartzose sandstones lacking the lithic and feldspathic debris characteristic of the internal tectonic land or the phyllites and micaschists fragments characteristic of the Verrucano-type sandstones[21].

The mineral composition of the Numidian quartzarenites in both Sicily and Tunisia is uniform, with 90–95 per cent of the sand fraction being composed of single-grained

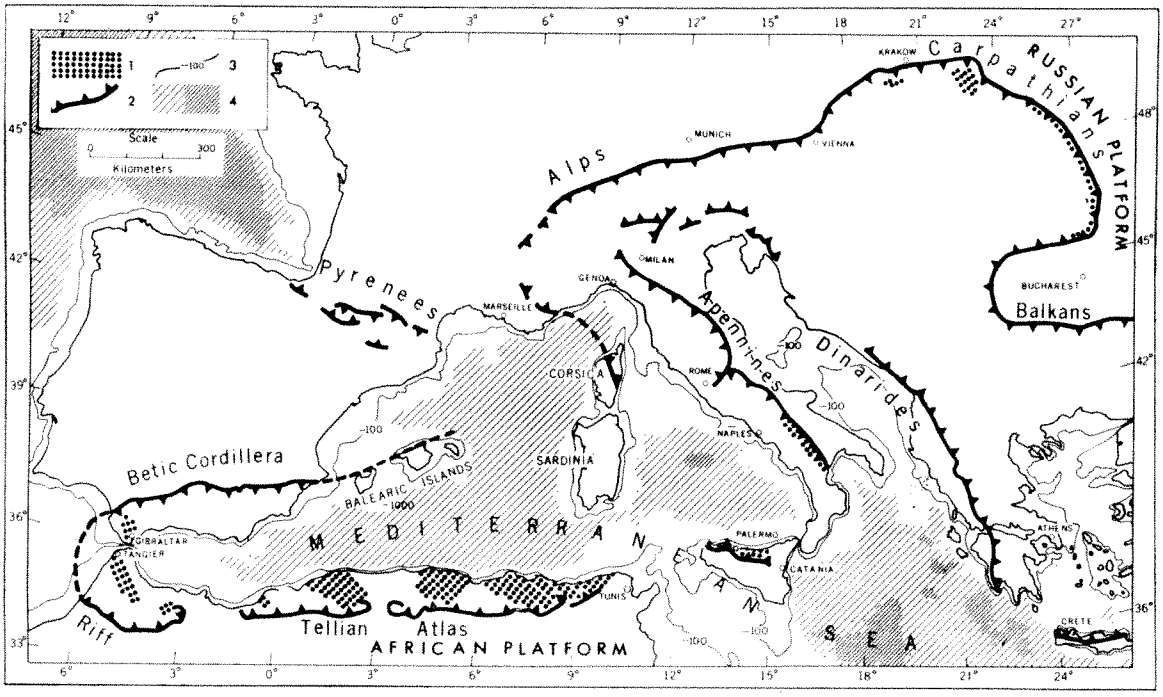

Fig. 1. Generalized tectonic sketch map of the Mediterranean showing the southern branch ("Perberides-Italo-Dinarides") and the northern branch (Alps-Carpathians) of Alpine mountain system (simplified and modified from ref. 30). Symbol legend: 1, general outcrop localities of Numidian Flysch (in southern branch) and Kliwa Sandstone (northern branch); 2, external sector of foldbelts; 3, offshore isobaths in fathoms; 4, depth respectively more than 1,000 fathoms (left symbol) and more than 2,000 fathoms (right symbol).

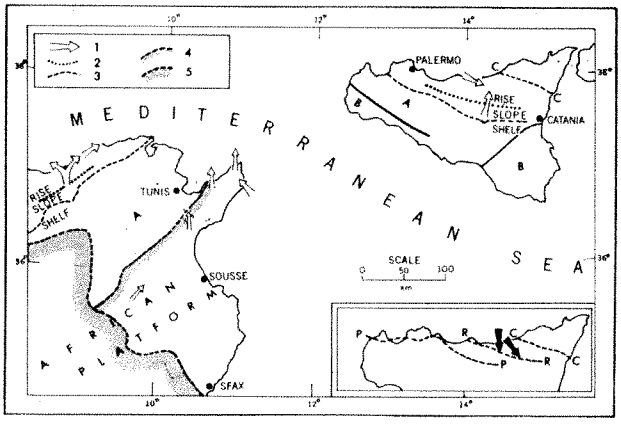

Fig. 2. Generalized map of Tunisia and Sicily showing distribution of facies and palaeocurrent directions in Oligocene–Lower Miocene sediments (Numidian Flysch and its shallower lateral equivalents) based on data in refs. 7, 8 and 31. The predominant directions of transport of Reitano Flysch are indicated (black arrows in inset). Symbol legend: 1, direction of sediment transport; 2, approximate base-of-slope position; 3, probable outer shelf edge; 4, inferred coastline during the Lower Miocene; 5, inferred coastline in pre-Lower Miocene time. *A*, Shelf facies with glauconitic sandstones; *B*, shelf facies with calcarenites and calcirudites; *C–C*, position of the internal massif nappe front (limestones and crystalline terranes of Calabride nappe); *R–R*, southern position of allochthonous Reitano Flysch; *P–P*, southern position of Panormide terranes.

"common" quartz that is usually rounded and has frosted surfaces, suggesting a probable aeolian origin. About 75 per cent of the transparent heavy minerals consist of zircon and tourmaline; rutile and garnets account for the remainder of the suite[7,15,22]. Moreover, the quartzarenites contain less than 5–10 per cent matrix and are often bimodal[7,15,16], with a coarse fraction mode of 0·5–4 mm and a fine fraction mode of 0·2–0·3 mm. This uniformly high mineralogical maturity and inherited bimodal texture, characteristic of inter-dune sands[23], indicate a provenance from older, rounded quartzose sediments transported on land and in shallow water for a long time before entry into the Numidian miogeosyncline.

All stratigraphic and sedimentological data that I have collected during the past 5 years indicate a southern derivation of the Numidian detritus from the pre-existing continental or epi-continental "Nubian Sandstone"[24] exposed over a large extent of the Saharan cratonic landmass along the southern edge of the Numidian trough.

In Sicily it is possible to recognize a lateral lithofacies continuum from south to north: facies 1, very coarse ultra-proximal sandstone, commonly friable and irregularly stratified; facies 2, finer proximal sandstone, well cemented with silica; facies 3, distal graded sandstone (turbidites and oceanic current deposits) mapped as the "Tavernola Formation". Facies 2 and 3 have been partly overthrusted above units of facies 1. Facies 2 probably represents deposits of coalesced submarine fans or continental rise deposits (recognized also by the presence of deep channels[26]), whereas facies 3 is interpreted as a near-axis trough deposit.

In Tunisia (Fig. 2), the following lithofacial distribution of Oligocene–Lower Miocene deposits is observed from south to north[7]: (1) continental facies, clean cross-stratified quartzose sandstones and laterite deposits; (2) shelf facies, quartzarenites with ripples and channels which indicate a northerly direction of sand transport ("Gres de Chérichira–Gres de Boghari"); a glauconitic sandstone outer-shelf subfacies is also present; (3) slope and rise facies, some 3,000 m of Numidian Flysch similar in all respects to the Numidian Flysch in Sicily; (4) basin facies, finely laminated quartzarenites (turbidites and perhaps oceanic contour current deposits similar to those of the Sicilian "Tavernola Formation") interfingering with the quartzarenites of the southern facies. The shelf facies, "Gres de Chérichia–Gres de Boghari", occasionally contains finer-grained quartzarenites than those of the Numidian Flysch. A sedimentary by-passing of coarse quartzose grains through some shelf-channels is inferred both in Tunisia and in Sicily[8].

It is worthwhile to note, for comparision, that similar palaeogeographic conditions and sedimentological features have been inferred for the Kliwa Sandstones intercalated in the Menilitic Shales of the Polish and Rumanian Carpathians[9–12]. This unit also occupies an external position near the foreland, and is exposed for about 800 km along the northern margin of the Carpathians (Fig. 1). The Kliwa Sandstones, consisting of a similar grain flow facies, are mature sands containing rounded and frosted quartzose grains[12]. As in Sicily[27] they locally include some diatomaceous horizons[28]. The Kliwa Sandstones pass laterally into sediments of the Krosno Flysch, lithic turbidite sandstones having compositional and sedimentary structures[29] similar to those of the Reitano Flysch.

This work was supported by the Italian National Research Council (C.N.R.), Geology of Sediments Group. I thank Dr Richard Cifelli for reviewing the manuscript, and Drs S. Dzulynski, G. Kelling, J. E. Sanders and D. J. Stanley for valuable suggestions and comments.

Variation of the Luminescence Lifetime of a Molecule near an Interface between Differently Polarizable Dielectrics

IN a recent paper[1] the energy transfer from an excited molecule S to an acceptor A was considered as a retardation effect. In classical terms, the field of S induces A to oscillate and the induced field of A, arriving at S, slows

down this oscillator. This effect may be studied, too, without A being an absorber, but simply a polarizable molecule, oscillating in phase with the radiation field of S at the location of A. Then the field which is produced by A and acting at S accelerates or slows down this oscillator depending on the phase relation to its motion; thus the decay time of the luminescence of S will be prolonged or shortened. This phase relation depends on the time needed for the propagation of the electromagnetic field from S to A and from A to S.

Let us look at a molecule S at a distance d from the planar interface between different dielectric bodies. It induces oscillating dipoles in all volume elements in these bodies and the field at S produced by these dipoles may be obtained as the sum of the contributions of each volume element. Neglecting interactions between induced dipoles the summation is easily possible and the following results are obtained

$$\frac{1}{\tau_d} = \frac{1}{\tau_d \mathrm{pa}} \cdot \sin^2\theta + \frac{1}{\tau_d \mathrm{pe}} \cdot \cos^2\theta \qquad (1)$$

oscillator at angle θ with normal on interface.

$$\frac{\tau_\infty}{\tau_d \mathrm{pa}} = 1 + \frac{3}{4} a \left(\mathrm{f}(x) - \frac{\sin x}{x} \right) \qquad (2)$$

oscillator parallel to interface.

$$\frac{\tau_\infty}{\tau_d \mathrm{pe}} = 1 + \frac{3}{2} a \left(\mathrm{f}(x) + \frac{\sin x}{x} \right) \qquad (3)$$

oscillator perpendicular to interface.

$$\frac{\tau_\infty}{\tau_d \mathrm{is}} = 1 + a\,\mathrm{f}(x) \qquad (4)$$

isotropic distribution. With the abbreviations

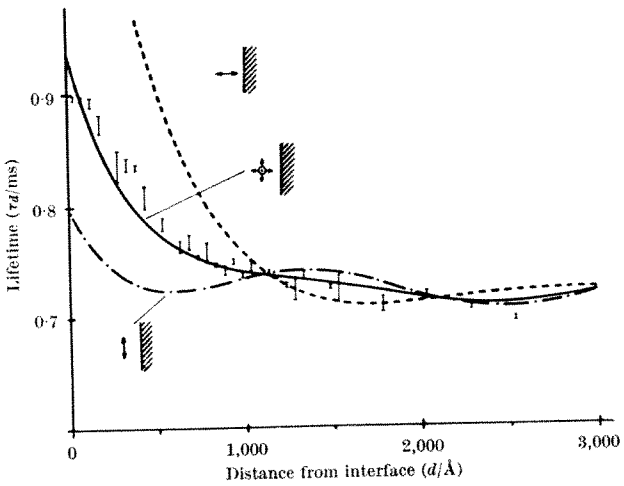
$$\mathrm{f}(x) = \frac{4 \sin x}{x^3} + \cos x - \frac{4 \cos x}{x^2} + x \left(\sin(x) - \frac{\pi}{2} \right) \qquad (5)$$

$$x = \frac{4\pi n_1 d}{\lambda} \qquad (6)$$

$$a = \frac{\alpha\pi}{n_1^2} q_\infty \; ; \; \alpha = \frac{3}{4\pi} \frac{n_2^2 - n_1^2}{2n_2^2 + n_1^2} \qquad (7)$$

τ_d is the relaxation time and λ the vacuum wavelength of the luminescence light; n_1 is the refractive index of the medium surrounding S and n_2 is the refractive index of the other medium. q_∞ is a quantum yield defined by the probability that a molecule in the luminescent excited state will emit a quantum of luminescent light, the environment being extended to infinity ($d = \infty$) (this quantity q_∞ must be distinguished from the easily accessible quantum yield of luminescence, which is number of emitted to number of absorbed quanta). According to (1), (2), (3) and (4) the luminescence decay time of a molecule must be markedly affected by the proximity of the interface between dielectrics.

A similar effect, the variation of the decay time of the fluorescence of a molecule in front of a metal mirror, was reported in refs. 2–4. (The experiments described in ref. 4 were proposed by F. P. Schäfer, first measured with clearly positive results by W. Sperling and then measured with increased precision by K. H. Drexhage, using equipment developed by F. P. Schäfer. Many implications of the effects were considered in ref. 5. K. H. Drexhage does not give credit to the above mentioned investigators associated with the early phase of that work.) The decay time was obtained there by superimposing the direct and reflected radiation field of the oscillating dipole, and by integrating the Poynting vector over a large sphere about the dipole. This method, when applied to the case of the reflexion at the interface between dielectrics, is much more involved than the method discussed here and in ref. 1. Drexhage[4] has applied the method in ref. 2 to that case and has measured τ_d independently.



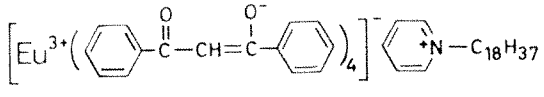


Fig. 1. Lifetime τ_d of the luminescence of europium complex I as a function of the distance d from the interface between monolayer system and air. Theoretical curves according to equations (2), (3), (4), with $n_1 = 1{\cdot}52$; $n_2 = 1$; $\tau_\infty = 0{\cdot}72$ ms and $q_\infty = 1$. — · — · —, Oscillator parallel to interface; - - - - -, oscillator perpendicular to interface; ———, isotropic distribution; bars, experimental results with root mean square deviation.

For experimentally realizing these effects the monolayer assembling technique[5,6] was used in the work cited in refs. 2–4 and in this article. This technique enables us to hold a fluorescent molecule at precisely adjustable distances from an interface (metal surface or surface of a medium with different refractive index) and to measure the decay time of the luminescence.

A monolayer of europium complex I

was deposited on a glass plate and superposed by tripalmitine. By exciting this arrangement with a flash of 366 nm light the intense red fluorescence ($\lambda = 612$ nm) of this complex is observed. The fluorescence follows an exponential decay law over at least two decades with a decay time of roughly a millisecond. Fig. 1 shows the decay time τ_d as a function of the distance d between monolayer of I and the interface of the monolayer system and air.

We assume the same value, $n_1 = 1{\cdot}52$, for the refractive index of tripalmitine and glass. The quantum yield of the fluorescence is $q_\infty = 1$. This value results from energy transfer experiments where I is used as a sensitizer[5] and from experiments of the decay time of the luminescence of I in front of a metal mirror[2,3]. By introducing the value $n_2 = 1$ (air) the curves are obtained from equations (2), (3) and (4) if the oscillator is assumed to be oscillating parallel to the plane of the layers, perpendicular and isotropic respectively. The experimental points correspond very well with the theoretical expectation for isotropic distribution.

The de-excitation of a molecule and appearance of a quantum of luminescent light is a discrete process and it seems surprising at first glance that the probability of this process may be changed considerably by placing the molecule in front of an interface which is quite far removed (in molecular dimensions). According to the above, this can be interpreted by representing the field, which determines the probability of observing the light quantum in a given space and time interval, by the classical electromagnetic field equations, showing that the probability of de-excitation of a molecule and appearance of a quantum of luminescent light does not depend only on the molecule but also on its broad environment. The result is a very direct manifestation of the wave particle duality of light.

This research was supported by the Deutsche Forschungsgemeinschaft. We thank Dr Sperling and Dr Sondermann for preparing the europium complex I.

Effect of Low Magnetic Fields on the Catalysed Parahydrogen Conversion Rate over Certain Rare Earths

The purpose of this communication is to report a change in rate of the parahydrogen conversion if the catalyst is placed in a magnetic field of a few oersteds. The change is a decrease of several per cent, and it has been observed over Pr_2O_3, Nd_2O_3, Sm_2O_3 and Yb_2O_3. It has not so far been observed over Eu_2O_3, Gd_2O_3, Tb_2O_3, Dy_2O_3, Ho_2O_3, Er_2O_3 or Tm_2O_3. But Tb_2O_3 supported at low surface concentration on high-area Al_2O_3 shows the effect.

In a typical experiment high purity rare earths are calcined in air at 800° C overnight. From 10 to 100 mg is then placed in the flow reactor and heated for 1 h in purified hydrogen at 550° C. Praseodymia and terbia require special treatment and are heated in hydrogen at 800° C for 12 h. A 1 : 1 *ortho-para* hydrogen mixture is then passed over the catalyst at from 25 to 50 ml. per min at 1 atmosphere pressure and at 25° C. Zero extrinsic field conversions average about 20 per cent of equilibrium and are monitored by differential thermal conductivity. The effect of placing the catalyst in a magnetic field is measured by assembling the reactor in the gap of a large electromagnet or, for fields of less than 40 oersteds (3,000 A m^{-1}), in a coreless solenoid of 5,000 turns. Fields are monitored by a commercial Hall effect instrument sensitive to 0·1 oersted (7·95 A m^{-1}).

In the conditions of the experiment no catalyst (except possibly the alumina-supported Tb_2O_3) shows any measurable hydrogen–deuterium equilibration; the applied field causes no change of hydrogen flow rate, no temperature effect and no shift of equilibrium. The changes in conversion rates appear to occur instantaneously, or almost so, on application of the field, and they are completely reversible. No such effects have been observed with the diamagnetic rare earths.

Fig. 1 shows the rate changes observed over supported Tb_2O_3 on so-called gamma-Al_2O_3 as a function of extrinsic field applied to the catalyst. This sample, prepared by impregnation of alumina with an aqueous solution of terbium nitrate, contained 0·14 atom per cent of Tb_2O_3 on a specific surface of 160 m^2. The rate changes are expressed as the fraction $(k_H-k_0)/k_0$ where k_H is the specific rate in a field H and k_0 that in zero extrinsic field. The value of k_0 was about 1×10^{-8} mole o-H_2 formed per second per cm^2 (of catalyst surface). This is probably accurate within a factor of two, a major source of uncertainty lying in the specific surface of the Tb_2O_3. The rate changes are quickly and accurately determined by turning the magnet current on or off. The determination is thus essentially differential and, consequently, the precision is high. The minimum change of rate detectable was about ±0·5 per cent of the zero field conversion rate.

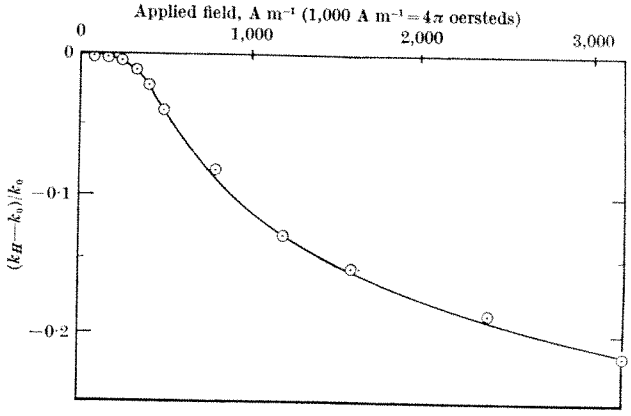

Fig. 1. Fractional change in the parahydrogen conversion rate over Tb_2O_3/γ-Al_2O_3 when the catalyst is placed in a magnetic field.

Fig. 1 shows the rate changes observed up to a field of 3,180 A m^{-1}. At much higher fields the rate rises as previously described for Cr_2O_3 above the Néel point[1,2], although the rise is much less for the supported Tb_2O_3 than for the pure rare earths[2]. It appears that the negative low-field effect described is not related to the much larger positive effects observed at high fields.

It will be noted in Fig. 1 that the effect of the extrinsic field changes rapidly, with field, in the region of 400–800 A m^{-1}. This suggests that, in this region, the Earth's magnetic field may be sufficient to influence the conversion rate. That this is indeed the case is readily shown by reversing the current in the solenoid. With the solenoid vertical and the angle of declination about 60°, reversal of the current gives a net resultant field change of about 80 A m^{-1}. It was found that, at 429 A m^{-1}, reversal of the current gave a readily perceptible change of rate, the greater change being found when the field produced by the solenoid was in the same direction (or nearly so) as the Earth's field. Field reversal gave no effect below 160 A m^{-1} and little or none above 8,000 A m^{-1}.

If the interaction of a molecule and a surface may thus be influenced by the Earth's magnetic field it would appear that a re-examination might be warranted of the possible role of terrestrial magnetism in such diverse areas as the navigational instincts of birds and the exclusive occurrence of L-amino-acids in natural proteins.

BIOLOGICAL SCIENCES

Evidence for a New Haemoglobin Chain (ζ-Chain)

The possibility of a human embryonic haemoglobin was first indicated by the work of Drescher and Kunzer[1]. Two such haemoglobins, Hb-Gower 1 and Hb-Gower 2, have been discovered[2,3] and their structures are ε_4 and $\alpha_2\varepsilon_2$, respectively. The ε-chain is a distinct haemoglobin chain synthesized during embryonic development. It has therefore been suggested[4] that there is a separate genetic locus determining the structure of the ε-chain, just as there

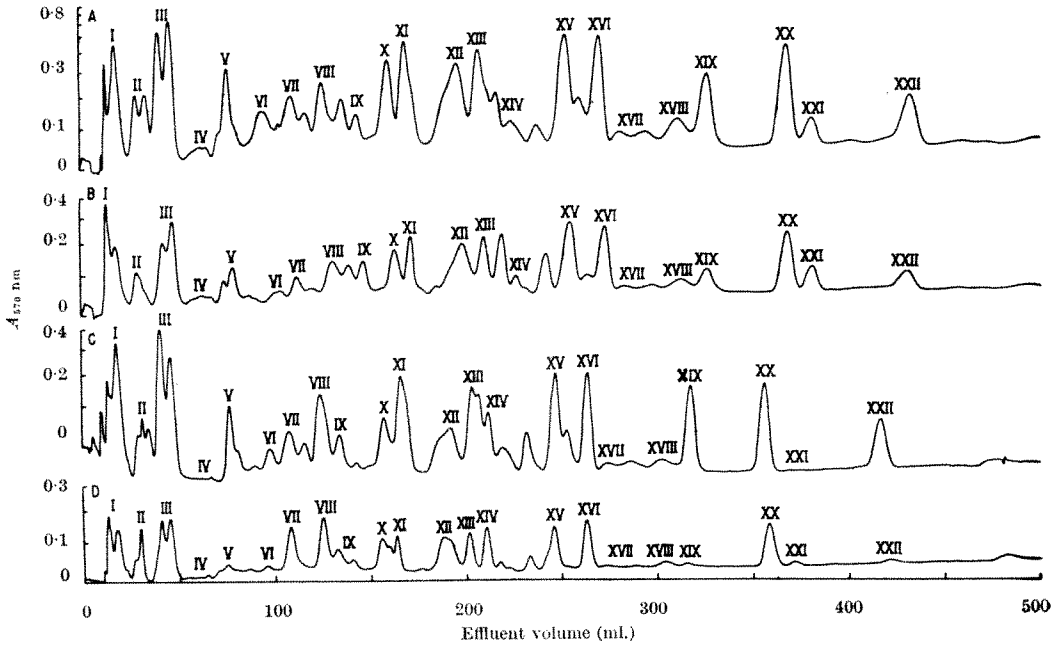

Fig. 1. Peptide patterns of complete tryptic hydrolysates: *A*, 3 mg of Hb-Portland 1 ($\gamma_4\zeta_2$); *B*, 2·4 mg of γ-chain from Hb-Portland 1; *C*, 2·2 mg ζ-chain of Hb-Portland 1; *D*, 2 mg of the γ-chain of haemoglobin F. Column was 0·9 × 17 cm Spinco 15 A resin; temperature 50° C. Development was with a linear gradient of 500 ml. of pyridine–acetate buffer beginning at *p*H 3·1, 0·2 M pyridine and ending at *p*H 5·0, 2·0 M pyridine (250 ml. of each). Column flow of 30 ml./h and ninhydrin flow at 15 ml./h.

are separate loci determining the structure of the α, β, γ and δ-haemoglobin chains[5].

The existence of a third embryonic haemoglobin, Hb-Portland 1, has been indicated; it is a tetramer (molecular weight 66,000) which is composed of a pair of γ-chains plus a pair of non-α-chains, previously designated as x-chains[6,7]. Haemoglobin Portland 1 was originally observed in a newborn infant with multiple congenital anomalies and complex autosomal chromosomal mosaicism[6,7], but it has since been found in several newborn infants with D_1 trisomy and in very small amounts even in newborn normal infants[8]. Here we present evidence that the x-chain is in fact a new human haemoglobin chain which we designated as the ζ-chain.

Tryptic peptide patterns of Hb-Portland 1 and of its γ and ζ-chains were obtained according to Jones[9]. The γ and ζ-chains were separated from Hb-Portland 1 globin by countercurrent distribution. The chains were then aminoethylated and digested with trypsin. In Fig. 1 the peptide patterns of the individual chains from Hb-Portland 1 and the γ_F-chain were compared with the peptide patterns produced by globin from Hb-Portland 1. These chromatograms illustrate that Hb-Portland 1 is a composite of normal γ plus ζ-chains.

The peptide zones shown in Fig. 1 were collected and, where necessary, were further purified by chromatography. The amino-acid composition of each Hb-Portland 1 peptide was determined using the Spinco amino-acid analyser. The following nine possible new peptides (ζT-peptides) were thus revealed and their composition is shown inside the parentheses. Two new peptides were obtained by the further chromatography of zone I: ζT-A (Lys, Thr, Ser, Leu) and ζT-B (Arg, Asp, Thr_1, Ser, Glu_3, Gly, Ala, Ile_2, Leu); one from zone II, ζT-C (Lys, Thr, Ser_2, Glu, Ala, Val_2, Leu_2, Phe); one from zone VII, ζT-D (Lys, Thr_2, Ser, Gly, Ala_2, Leu); one from zone VIII, ζT-E (His, Ser, Glu, Ala, Leu_2, Tyr); one from zone XI, ζT-F (Lys, His, Thr, Ser, Glu, Pro, Leu_2, Phe); two from zone XV, ζT-G (Arg, Ile, Leu) and ζT-H (Lys, His, Ser, Gly, $Ala_{1\ or\ 2}$, Cys, Leu_2); and one from zone XIX, ζT-I (Lys, His, Ser, Gly, Ala). These nine peptides differ from any of the tryptic peptides of the α, β, γ and δ-chains, indicating that the ζ-chain is not identical to any of these four haemoglobin chains. A peptide, ζT-J, was isolated from zone XXII and found to consist of one arginyl residue and one tyrosyl residue. Its composition and chromatographic behaviour indicate that it is identical to the tryptic peptide T-14 at the carboxyl-terminus of the α-chain. It is present, however, in sufficiently high amounts to rule out the possibility that it may arise from contamination with α-chains and should therefore be regarded as an integral part of the ζ-chain. In addition to these peptides, several tryptic peptides were isolated which had compositions identical to tryptic peptides of the γ-chain.

The peptide pattern of the ζ-chain differs from the peptide patterns of the α, β and δ-chains and the amino-acid composition (Table 1) of the ζ-chain is quite different from any of these chains. Similarly, comparison of the peptide patterns (Fig. 1) and amino-acid compositions (Table 1) of the ζ-chain and γ-chain reveals differences. Furthermore, recent studies on the structure of human embryonic haemoglobins by Szelenyi *et al.*[10], and A. Yoshida (personal communication) elucidated the amino-acid composition of two peptides that are unique to the ε-chain. These two peptides differ from any of the nine new tryptic peptides of the ζ-chain. A comparison of the amino-acid composition of the ε-chain[11] with that of the ζ-chain (Table 1) reveals further differences between the chains. This firmly establishes the existence of this new chain and indi-

cates that there is a separate ζ-chain locus determining its structure.

Further work on the ζ-chain of the Hb-Portland 1 is currently under way on haemoglobin samples obtained in Hong Kong from Chinese stillborn infants with erythroblastosis fetalis, due to homozygous α-thalassaemia.

This work was supported by a US Atomic Energy Commission contract and a US Public Health Service research grant.

Note added in proof. Two recent papers provide similar conclusions about the uniqueness of the ζ-chain (D. J. Weatherall, J. B. Clegg and W. H. Boon (*Brit. J. Haematol.*, **18**, 357; 1970); and D. Todd, M. C. S. Lai, G. H. Beaven and E. R. Huehns (*Brit. J. Haematol.*, **19**, 27; 1970).

Formate, a New Component of Bacterial Exopolysaccharides

THE occurrence of non-carbohydrate substituents in bacterial exopolysaccharides has been well documented. Acetate and pyruvate have frequently been detected either separately or together in the same polysaccharide[1,2]. More recently, a polysaccharide secreted by *Alcaligenes faecalis* var. *myxogenes* was shown to contain succinate[3]. Although formate is known as a bacterial metabolite it has not previously been reported as an integral component of bacterial extracellular polysaccharides. This may be partly because of the lack of suitable methods for detection or estimation of formate and also because of the known lability of O-acyl groups on carbohydrates.

The basic structure of the polysaccharide forming the extracellular slime or capsule of *Klebsiella aerogenes* type 54 (strain A3) was established by chemical methods[4]. A repeating unit structure was identified as β-cellobiosyl-α-glucuronosyl-1→3-fucose. When the polysaccharide from this strain was hydrolysed with phage-induced depolymerase enzymes, two products were obtained[5]. Each was identified as a tetrasaccharide with the same structure as the repeating unit of the polysaccharide, but one of these oligosaccharides was acetylated while both contained an unidentified substitutent.

The polysaccharide did not contain pyruvate or succinate. Unlike O-acetyl groups, the unknown component was not removed by mild alkaline treatment (0·01 M KOH at 20° C for 16 h), but was absent after mild acid hydrolysis (0·05 M H_2SO_4 at 100° C for 15 min). Hydroxamic acid derivatives were prepared from acid hydrolysates of the polysaccharide by the method of Thomson[6] and compared with authentic compounds by descending paper chromatography in butan-1-ol–acetic acid–water (4 : 1 : 5, upper phase) for 20 h. Spots were revealed by spraying with 10 per cent ferric chloride solution. After drying at room temperature, two spots were present with R_F values 0·51 and 0·43 respectively. These were exactly equidistant with acetylhydroxamic acid and with formylhydroxamic acid respectively. To confirm that formate was a substituent of the polysaccharide and of oligosaccharides derived from it, the enzyme formate dehydrogenase was prepared from *Pseudomonas oxalaticus*[7]. This enzyme is specific for the NAD-linked oxidation of formate and is unaffected by the presence of acetate. Assay of mild acid hydrolysates of the polysaccharide or the oligosaccharides obtained by depolymerase treatment gave reduction of NAD in the presence of formate dehydrogenase. By comparison with standards, the formate content of samples was calculated to be in the approximate ratio of one mole formate per mole of fucose or glucuronic acid. Calculated on a dry weight basis the polysaccharide contained 46·5 per cent glucose, 19·1 per cent fucose, 20 per cent glucuronic acid, 6·3 per cent acetate and 6·2 per cent formate. Some loss of formate could be expected because of the volatility of the free acid obtained after acid hydrolysis of the samples. A similar result was obtained for the acetylated tetrasaccharide. The non-acetylated tetrasaccharide also contained one molar equivalent of formate. It is also possible to estimate the presence of formate by reduction to formaldehyde and use of the chromotropic acid reagent[8]. Using this method, the formate content of the non-acetylated oligosaccharide was in good agreement with the value obtained by the enzymic method.

The sugar which is formylated is not known, but one residue can definitely be excluded. Treatment of either tetrasaccharide with a β-glucosidase preparation liberated one mole of glucose in each case. The other product was a trisaccharide containing either formate or formate and acetate. Further enzymic hydrolysis was not possible. Attempts to isolate a formylated sugar by graded acid hydrolysis have also proved unsuccessful.

Preliminary experiments indicate that formate is present in the extra-cellular polysaccharides of several other *K. aerogenes* strains. It is not present in all strains, however, and it remains to be seen how widespread is the occurrence of formate in polysaccharides of other bacterial species or of non-bacterial origin.

Transduction in *Mycobacterium smegmatis*

SEVERAL people have studied lysogeny and lysogenic conversion in the advanced prokaryote, *Mycobacterium*[1–3], and presented evidence for reciprocal genetic exchange from the lysogenic to the non-lysogenic state. Biochemical and physiological changes induced by lysogenization of *M. phlei* with mycobacteriophage B2 have been demonstrated by Juhasz[4]. We wish to report the isolation of a mycobacteriophage capable of mediating transduction in *Mycobacterium smegmatis* strain SN2, thus providing an opportunity to study the genetics of mycobacteria.

M. smegmatis strains SN2 and EB165 were provided

by Dr R. Bönicke (Borstel Research Institute for Experimental Biology and Medicine, Borstel, Germany). Luria broth[5] supplemented with 'Tween-80' (0·05 per cent) was used for propagation of bacterial cultures, and Bordet–Gengou broth base[6], solidified with 2 per cent Difco agar, was used for phage titration. All cultures and phages were propagated at 37° C. The minimal medium used was a half-strength preparation of medium 56 (ref. 7). *M. smegmatis* SN2 was treated with ultraviolet light to a survival of 1 per cent, or with N-methyl-N′-nitro-N-nitrosoguanidine to a survival of 1–5 per cent. The standard procedures[8,9] for isolation of auxotrophs were modified to suit the nature of mycobacteria by addition of 'Tween-80' to minimize clumping. After mutagenic treatments, cells were plated and screened for auxotrophs, which were all very stable after isolation; the reversion frequency to prototrophy in the case of single auxotrophs was of the order of 1×10^{-9} to 1×10^{-10}.

Ten independent isolations of mycobacteriophages were made from soil samples by an enrichment technique according to the method of Froman *et al.*[6]. Of the ten phages isolated against *M. smegmatis* SN2, one phage, I3, forms turbid plaques on strain SN2 but clear plaques on strain EB165. The phage has a wide host range on related mycobacteria. Phage adsorption is independent of Ca^{2+}, Mg^{2+} or tryptophan in the medium or of the growth phase of the bacterium. The average burst size is about 60, with a latent period of 250–270 min. Phage were propagated by a soft-agar layer technique[10] and using a bubbler tube with aeration[11].

For transduction studies, recipient cultures grown overnight on a shaker were centrifuged, and resuspended in warmed, fresh Luria broth. They were infected at a multiplicity of infection of 1–2 with phage lysate free of chloroform. Details of transduction are presented in Table 1.

Table 1. TRANSDUCTION OF *M. smegmatis* SN2 MUTANTS BY PHAGE I3 PROPAGATED ON WILD STRAIN SN2

Phage lysate	Transductants per ml. Glycine	Histidine	Arginine	Alanine	Adenine
Experiment	$2{\cdot}4 \times 10^2$	$4{\cdot}7 \times 10^2$	$1{\cdot}4 \times 10^2$	$1{\cdot}2 \times 10^2$	$2{\cdot}4 \times 10^2$
Treated with antiserum	0	0	0	0	0
Treated with deoxyribonuclease	$2{\cdot}4 \times 10^2$	$4{\cdot}6 \times 10^2$	$1{\cdot}3 \times 10^2$	$1{\cdot}2 \times 10^2$	$2{\cdot}4 \times 10^2$

5×10^8 cells of the mutants of SN2 were incubated at 37° C for 45 min with I3 phage (1×10^9 plaque forming units) propagated on wild type strain SN2. Aliquots (0·1 ml.) of washed cells were plated on minimal media. Transductants were stored after incubation of the plates for 4–5 days at 37° C.
The phage lysate was pretreated in turn with antiserum (K–10) and deoxyribonuclease (50 μg/ml. at 37° C for 30 min).

Transduction has been demonstrated for histidine, glycine, arginine, alanine and adenine markers. Colonies remain sensitive to phage after transduction. Treatment of phage with phage antiserum destroys the transducing ability. At a low multiplicity of infection, the frequency of transduction is very much reduced. To eliminate the possibility of transformation, lysate was pretreated with deoxyribonuclease[12]. This did not reduce the number of transductants detected.

These results can be extended to the study of the chromosome of *M. smegmatis* with respect to various functions. Although few markers have been transduced so far we intend to look for transduction of markers for sugar fermentations, synthesis of other amino-acids and resistance to streptomycin and the drug isoniazid, to which only mycobacteria are susceptible.

We thank Professor M. Sirsi for interest in this work and Dr K. P. Gopinathan for helpful discussions. This work was supported by grants from the Indian Institute of Science, University Grants Commission, India, and the Department of Atomic Energy, India.

Detection and Identification of Monoamine Oxidase Inhibitors in Biological Samples

THE monoamine oxidase (MAO) inhibitor drugs are now widely used in psychiatric practice for the management of various types of neurotic and psychotic depressions; unfortunately, these therapeutically valuable drugs are implicated in an increasing number of severe and sometimes fatal accidents caused either by gross overdosage, producing symptoms of hypernoradrenalinaemia[1] or more frequently by interacting with other drugs such as sympathomimetic amines[2–5], amine precursors[6–9], central nervous system depressants[10–12] and also with foods containing tyramine, DOPA and other amines[13].

In most poisoning cases involving MAO inhibitors, the toxicologist is in a difficult position because the inhibited enzyme is resynthesized very slowly, so that the toxic effects of the drug or of its association with other compounds may occur several days after the inhibitor has been almost completely excreted; consequently, at the time of the analysis he will very often recover smaller traces of the drug than can be detected by current chemical methods based on the development of a coloured reaction with relatively non-specific agents, such as dimethylaminobenzaldehyde or Folin Ciocalteu reagent.

We wish to describe a very sensitive and specific method for the detection and identification of these drugs, based on the inhibitory action of these substances on the activity of MAO; this activity is demonstrated by use of a system including nitro blue tetrazolium and an indole amine substrate, tryptamine. The enzyme oxidizes tryptamine into an aldehyde which in turn reacts with the dye to form a blue formazan[14–16].

Rat liver mitochondria provide the MAO; after homogenization of fresh rat livers in 0·3 M sucrose, mitochondria are isolated by the method of Hawkins[17] and stored at −10° C. A suspension of MAO is prepared by diluting 1 ml. of the mitochondria preparation with 3 ml. of 0·1 M phosphate buffer, *p*H 7·4. The different MAO inhibitors in the free base form—harmine, iproniazid, isocarboxazid, nialamide, pargyline, phenelzine, pivhydrazine and tranylcypromine as well as isoniazid, a weak MAO inhibitor chemically related to the most potent hydrazine derivatives—are extracted by vigorous shaking with freshly distilled ether from an aqueous solution at *p*H 10. The organic solvent is dried with solid sodium sulphate, evaporated under nitrogen to near dryness and transferred to a silica gel G thin layer plate which is then developed in chloroform and ethyl acetate (1 : 1).

After evaporation of the solvent, the plate is sprayed with the enzyme suspension and incubated for 15 min in a moisture tank kept at 37° C. The plate is then developed for MAO activity by spraying with a solution containing 10 mg of nitro blue tetrazolium, 10 mg of tryptamine HCl and 1 mg of sodium sulphate in 5 ml. of 0·1 M phosphate buffer, *p*H 7·4. The plate is incubated

Table 1. THIN-LAYER CHROMATOGRAPHY OF THE DIFFERENT MAO INHIBITORS ON SILICA GEL G PLATES IN ETHYL ACETATE : CHLOROFORM (1 : 1)

Drug	R_F
Nialamide	0·00
Harmine	0·04
Iproniazid	0·07
Tranylcypromine	0·11; 0·88
Phenelzine	0·50; 0·68; 0·83
Pivhydrazine	0·58
Isocarboxazide	0·70
Pargyline	0·79

for 2 h at 37° C, in the moisture tank without being moved. Areas of MAO inhibition appear very distinctively as white spots on a dark blue background, at different heights on the plate according to the respective R_F of the drug concerned (Table 1).

All the drugs tested, except isoniazid, inhibited dye reduction. Apart from its specificity, this method has a very high sensitivity permitting the detection of 10 ng of these drugs.

The chromatography of phenelzine and tranylcypromine reveals the presence of respectively three and two active distinct spots. Studies to elucidate the chemical nature of these compounds are now in progress.

We thank Dr M. Sandler and Dr G. G. S. Collins for the mitochondria.

Effect of 6,6′-Dithiodinicotinic Acid on the Dissemination of Ehrlich Ascites Tumour

PREVIOUS studies have shown that 6,6′-dithiodinicotinic acid (carboxypyridine disulphide, CPDS), while reacting with —SH groups of Ehrlich ascites tumour cells, does not enter these cells to any appreciable extent[1,2]. The reaction of CPDS with cell —SH groups leads to the formation of stable mixed disulphides[3,4].

as in the case with other disulphides of analogous structure[2]. Other types of cells, such as human lymphocytes and blood platelets[4], or mouse kidney (unpublished observations), are similarly affected by CPDS. The effect of CPDS treatment on the mammalian cells studied is two-fold: (*a*) the external —SH groups are blocked, and (*b*) this blocking introduces one carboxyl group on the cell surface for each —SH blocked. This interaction is described in more detail elsewhere[3]. Because —SH groups are not ionized at physiological *p*H, but carboxyl groups are, the net charge of the cell is made more negative by this treatment. It is known[3] that this modification does not effect respiration and glycolysis of Ehrlich ascites cells.

CPDS, when injected intraperitoneally in Swiss mice, in single doses as high as 1 g/kg, has no visible toxic effects. Daily injections of 450 mg/kg (in two daily doses), for 21 consecutive days, also had no visible effects. In all cases a solution of the sodium salt of CPDS was injected, prepared by dissolving the acid in sodium bicarbonate solution.

The mixed disulphides formed from cell —SH groups and 6-mercaptonicotinic acid (by the action of CPDS on cells) are split by thiols such as glutathione or cysteine. It can therefore be expected that in the living animal this —SH blocking group may be removed by physiologically available thiols. To estimate the approximate life of these mixed disulphides in the living mouse, ascites bearing mice were injected intraperitoneally with 6 mg of CPDS/mouse (in bicarbonate solution). The mice were killed at different times after injection (1–20 h), the ascites fluid was withdrawn. the Ehrlich ascites were separated by centrifugation and washed, and the amount of 6-mercaptonicotinic acid combined with the cells was determined, as described elsewhere[3]. The results indicated that the —SH groups of ascites cells in these mice remained blocked for about 4 h. This was taken as starting point for our studies on the effect of CPDS on the dissemination of Ehrlich ascites tumour.

As already reported[5,6], a marked dissemination of cancer cells to the lungs takes place in mice transplanted intracerebrally with Ehrlich ascites cells. We have used this system to study the effect of CPDS on the dissemination of this tumour, and applied the technique described by Rosso and his colleagues[5], adapted to our particular strain of tumour. A constant number of Ehrlich ascites cells (about 200,000) was injected into the brain of each mouse. After 7 days, the lungs were excised, and minced lung fragments (about 80–100 mg per implant) were transplanted subcutaneously in the retroscapular area of normal Swiss mice, on both sides. After 30 days the tumours were excised and weighed. The presence of a tumour weighing 100 mg or more was taken as evidence that in the donor mouse the tumour had spread from the brain to the lungs. Retroscapular tumour weights up to about 7 g were found in our experiments. The control group of mice was given intraperitoneal injections of physiological saline (0·1 ml.) every 4 h for 7 days (and nights) starting 1–3 h after the intracerebral injection of tumour cells. The test group was given intraperitoneal injections of CPDS (2 mg/mouse, or about 100 mg/kg) in sodium bicarbonate solution (0·1 ml.) at the same intervals. The results of these experiments are reported in Table 1.

Clearly the extent of dissemination of the tumour from the brain to the lungs is substantially reduced by CPDS. In each of these experiments the extent of

$P < 0.001$, evaluated for the sum of all the experiments ($\chi^2 = 37.7$; d.f. = 1).

spreading in the treated group was only a quarter of that of the control group. I hope to determine whether this is the result of blocking of the —SH groups, or the modification of the charge of the cell surface or both. Studies on the spread of cancer cells from implant sites other than brain (for example, bone marrow) will also contribute to establishing the mechanism of action of CPDS.

It is interesting to note that, when CPDS was injected only once or twice daily, even in total amounts larger than those of the experiments reported, no decrease in tumour dissemination occurred. This confirms the assumption that the dissemination of Ehrlich ascites cells is prevented only as long as the concentration of CPDS in the organism is sufficient to maintain the blocking groups on the cell surface sulphydryls.

I thank Sally C. Dion for help in the animal experiments, and Dr Howard M. Myers for useful discussion. This work was supported partly by private means. A patent application has been filed.

^{137}Cs Levels in Human Adult Population in California, 1960–69

THE presence in humans of caesium-137, a radioactive product of nuclear fission, was demonstrated in 1955[1] and ubiquitous distribution has since been described in population samples in Great Britain[2–4], Europe[5–9], Japan[10] and North America[11–21]. The long physical half-life of ^{137}Cs (30 years), coupled with its ease of absorption into the human body, has stimulated numerous studies of its metabolic behaviour and continuing evaluations of its hazard to human health. This report presents the results of 1,052 measurements of ^{137}Cs levels in 454 persons during the decade 1960–69.

The subjects, of both sexes, were all more than 20 years old and lived in or near Los Angeles, California. The quantitative measurements of ^{137}Cs, together with naturally occurring potassium-40, were made by analyses of the gamma spectra obtained with a "total body counter" consisting of four sodium iodide crystal scintillation detectors in a steel-lined room, and a multichannel pulse height analysis system, as described previously[12]. The accuracy of the technique ($\sigma = \pm 4$ per cent for ^{40}K and ± 10 per cent for ^{137}Cs) agreed closely with the accuracies reported for fifteen other "body counters"[22].

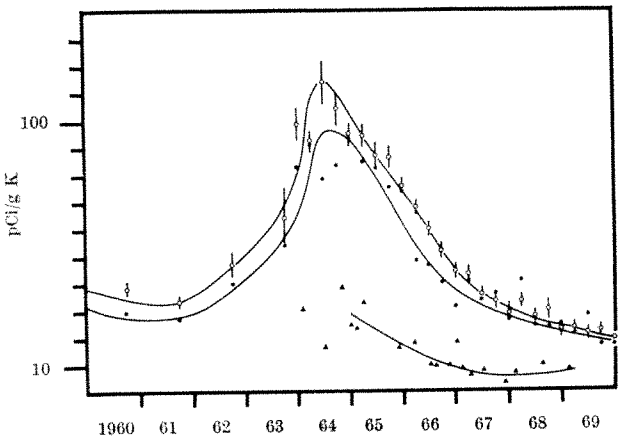

Fig. 2. Mean values of ^{137}Cs activity in human males (○) and females (●), and a hospital diet (▲) in southern California, tabulated quarterly. The vertical lines represent the standard error of the mean values ($\sigma/N^{1/2}$).

Fig. 1 shows the trend of individual values, expressed as picocuries of ^{137}Cs per g of K ($Ci \times 10^{-12}$/g K) over the ten year period. The peak of bodily contamination during 1964–65 occurred about 12–15 months after the cessation of detonations of nuclear devices in the atmosphere by the United States and the Soviet Union. Subsequent nuclear testing programmes conducted in the atmosphere by France and China have not reversed the downward trend since 1965, but have significantly slowed the rate of decrease particularly in 1968–69. This effect of recent injections of ^{137}Cs into the environment is seen more clearly in the flattening of the curves after late 1967 in Fig. 2, which presents the mean values of ^{137}Cs/g K for men and for women, tabulated by quarterly periods. In fact, if the quarterly mean values are replotted on semi-logarithmic graph paper, the points from mid 1965 through 1967 can be described quite well by a single declining exponential function, with a slope corresponding to a half-time of about 17 months. Since early 1968, however, the decline in body burdens has departed from this exponential rate and, indeed, values of ^{137}Cs/g K for early 1970 have remained at about the same level as in 1969. The consistently higher concentration of ^{137}Cs observed in men, compared with women, has previously been reported by a number of other investigators. Fig. 2 also gives the concentrations of ^{137}Cs in 7 day pooled, regular diets obtained bimonthly from a local hospital[23]. The ^{137}Cs/K ratios in the human subjects were about three times greater than the ratio in the dietary samples. Whether or not they truly represented the diets of the persons we

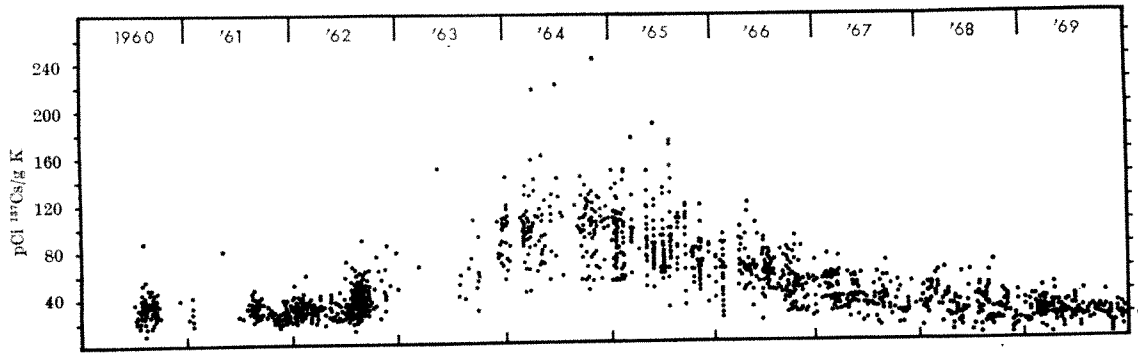

Fig. 1. ^{137}Cs levels in human population in Southern California, 1960–69.

measured is, of course, unproven, but the finding agrees with the three-fold difference in $^{137}Cs/K$ ratio reported for humans and their diets by Gustafson[18]. It is interesting that the plots of the ^{137}Cs concentrations in each of eight individuals which were measured periodically over a span of 6–10 years were essentially similar to the curves of quarterly mean values for the population shown in Fig. 2.

What has been the radiation dose sustained by members of this particular population as a result of the continued presence of ^{137}Cs in their bodies during the past ten years? A reasonable estimate can be made by calculating the absorbed radiation dose to a hypothetical "standard man" in whom the level of ^{137}Cs fluctuated according to the curve for quarterly mean values for males shown in Fig. 2. A total body mass of 70 kg with a potassium content of 135 g was assumed. The concept of "absorbed fraction" introduced by Ellet, Callahan and Brownell[24] and developed in detail for target body organs in the MIRD pamphlets[25] was used, together with the equilibrium absorbed dose constants for ^{137}Cs and ^{40}K. The total body concentration of ^{137}Cs, combined over the ten year period, was obtained by planimeter measurement of the area under the mean curve for males in Fig. 2. The calculated absorbed doses to total body, to marrow and to the gonads were between 8 and 10 mrads for the 10 year period. These values include the doses delivered by all beta particles, primary photons, conversion electrons and X-rays from the disintegration of ^{137}Cs nuclei. To place this radiation dosage in perspective, the total dose delivered simultaneously by the natural ^{40}K continually present in the body, calculated by the same method, came to 156 mrad. In our population sample, no individual had a ^{137}Cs burden greater than twice the quarterly mean value, from which we infer that very few persons in the area received as much as 20 mrad and we conclude that the average dose attributable to ^{137}Cs internal contamination was about 10 mrad, or about 6 per cent of the radiation received from the body potassium. This is close to the United Nations Scientific Committee estimate[26] of the long-term worldwide ^{137}Cs contamination, of 15 mrad absorbed dose as a consequence of the nuclear explosions carried out before 1966. Although the major part of this dose has now been delivered, ^{137}Cs will be with us for many years to come. Programmes to monitor it must therefore continue.

We thank R. Van Deusen for dealing with electronic problems during these many years. This work was supported by the United States Atomic Energy Commission.

Effect of Lithium on Foot Shock Aggression in Rats

Lithium has been shown to be effective in the treatment of mania[1–3], and it reduces aggressive behaviour in Siamese fighting fish and small rodents[4]. I have investigated the action of lithium on aggressive behaviour in rats subjected to foot shock. This type of aggression has been well described already[5,6].

Sprague–Dawley male rats (280–350 g, Charles River Laboratories) were used. The testing apparatus consisted of a clear plastic box, 23 × 20 × 20 cm, with a grid floor through which graduated electric current was delivered. Animals received either 5 mequiv/kg of lithium chloride or the same volume of physiological saline by intraperitoneal injection on five consecutive days. At this time there is a significant change in brain serotonin metabolism[7].

To measure the flinch–jump threshold[8], each rat was placed in the test box and a series of unavoidable shocks were delivered to its feet. Ten series of ten stimulations at shock intensities varying regularly in steps from 0·1 to 3 mA were given. Shocks lasted 1·0 s and were presented 30 s apart at 2 min intervals. One of three responses was recorded to each shock: no response, "flinch" (a startle or crouch behaviour in which animals' feet did not leave the grid), or "jump" (removal of two or more paws from the grid). Twenty rats were tested after receiving lithium and twenty after receiving saline.

In the foot shock aggression experiment, pairs of rats matched for size and weight were placed in the test box. Twenty pairs had been pretreated with lithium chloride and twenty with saline. After behavioural habituation to the cage, pairs were subject to increasing intensities of shock to the feet. At each intensity, shocks were delivered thirty times a minute, lasting 1·0 s for a total of 1 min. This was repeated five times at 2 min intervals. There was a 5 min interval between different intensities. The latency to fighting behaviour was measured with a stopwatch.

The jump threshold was defined as the average shock intensity at which the jump response occurred in ten series. For control animals injected with saline, the mean value for the jump response was 1·08 mA with standard deviation of 0·10. For lithium treated animals the mean was 1·10 mA with an s.d. of 0·15 (Table 1). Thus there was no significant difference between animals treated with saline and lithium as far as the jump response to foot shock was concerned. There was also no significant change in the flinch threshold.

The threshold for foot shock aggression was defined as the mean latency to attack in seconds for the five series of shocks at each intensity. Latency to aggression was defined as 60 if no fighting occurred within 1 min. There was a significant difference in the latency to fighting

Table 1. THRESHOLD INTENSITY FOR JUMP RESPONSE IN MILLIAMPS (mA) IN RATS PRETREATED WITH LITHIUM CHLORIDE (5 MEQUIV/KG) OR PHYSIOLOGICAL SALINE FOR 5 DAYS

Treatment	No.	Mean jump threshold MA

* Difference from saline treated animals significant $P < 0.001$.

behaviour between saline pretreated and lithium pretreated rats at all intensities studied (Table 2). There was a marked tendency for rats treated with lithium not to fight at intensities which provoked fighting in those treated with saline. Moreover, rats treated with lithium sustained high levels of shock intensity without fighting.

The prolongation of the latency to attack in pairs of rats treated with lithium and subjected to foot shock indicates that lithium can have an inhibiting effect on aggressive behaviour induced by pain. That this effect is not due to an altered threshold to painful stimulation is demonstrated by the findings in the flinch jump experiment, when there was no alteration in the intensity of stimulation required to produce the flinch jump in lithium pretreated animals.

I thank Mrs Diane Londroth for technical assistance. This work was supported by a grant from the US Public Health Service.

Epidermis and Pheromone Production in Males of the Desert Locust

SYNCHRONOUS sexual maturation among crowded males of *Schistocerca gregaria* is achieved through a pheromone produced by the cells of the epidermis[1,2]. The synthesis and release of the pheromone have been correlated with marked histological changes which occur in the appearance of the epidermis during maturation[2]. I have examined the development of the epidermis in males of *S. gregaria*, and have found that the changes associated with maturation are more interesting than previously thought.

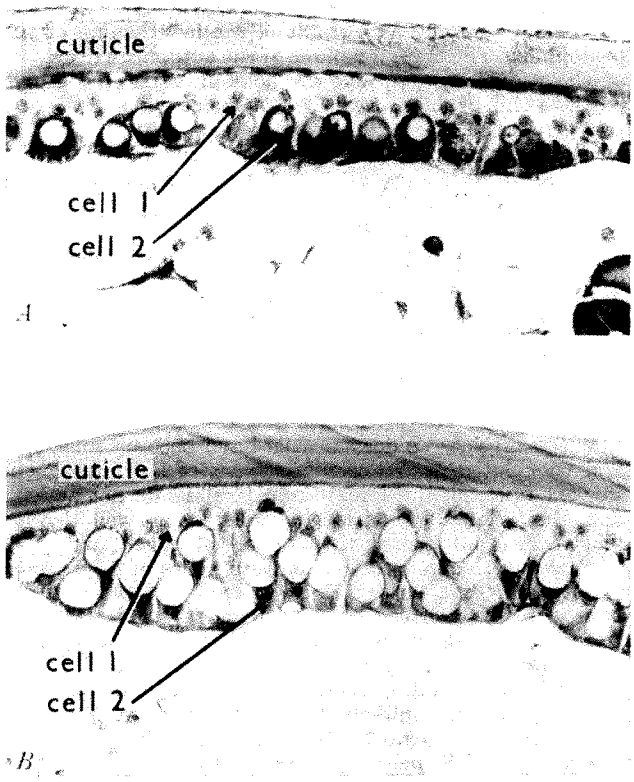

Fig. 1. Transverse sections of the third abdominal tergite of males of *S. gregaria*. *A*, Male locust at the onset of maturity (16 days) showing original epidermal cells (cell 1) and developing acidophils (cell 2). ×64. *B*, Mature male locust (21 days) showing the acidophils with large vacuoles. The acidophils are also lengthened, giving the epidermis a multi-layered appearance. ×64. All material fixed in Bouin's solution and stained with Mallory's triple stain.

Desert locusts were reared under conditions described previously[3], and males were killed at various stages of adult life—from emergence to sexual maturity (28 days). The third abdominal tergite was fixed in Bouin's solution, embedded in ester wax (60° C), and sectioned at 10μ. The sections were stained with Mallory's triple stain.

As reported earlier[2,3], the epidermis of the newly ecdysed male has the appearance of a simple squamous epithelium: the cells are narrow and the nucleus occupies the majority of the cell. During the following 14 days the cells increase slightly in volume, an increase which seems to be associated with the completion of cuticle formation. Until the onset of sexual maturity the epidermis undergoes little modification. As sexual maturity advances, the integument assumes the characteristic yellow coloration, and the epidermis is transformed from a simple epithelium into a compound epithelium of large vacuolated cells, which earlier workers have interpreted in terms of elongation and vacuolation of the original epidermal cells[2,4]. This transformation is caused not by the alteration of the original epidermal cells, but by the appearance, growth and vacuolation of additional cells. Between the basement membrane and the original epidermal cells (Fig. 1*A*, cell 1) appear new cells (Fig. 1*B*, cell 2) which are clearly differentiated from the original epidermal cells. The cytoplasm of the new cells reacts strongly with the acid fuchsin part of Mallory's stain, and they appear as deep-red cells among the neutral-staining epidermal cells. The site of origin of the acidophils is not known, but they are not apparent in the

epidermis of the immature male. The vacuole appears in the acidophil almost as soon as the cell itself can be distinguished, and grows in the distal part of the cell, pushing outwards into the epidermal cells which separate the acidophils from the cuticle (Fig. 1*A*). The compound layer of epidermal cells and acidophils increases greatly in thickness largely as a result of the lengthening of the acidophils. The overall volume of the cytoplasm decreases as the vacuole grows, and the acidophils become drawn out into thin columns with their vacuoles perched distally away from the basement membrane (Fig. 1*B*). In regions where the acidophils are very numerous many do not elongate—presumably as a result of competition from bordering cells—and the cytoplasmic stalk remains short. This creates the impression of a multi-layered epidermis of vacuolated cells (Fig. 1*B*). As the vacuole reaches its final volume the remaining cytoplasm of the acidophil is reduced to a thin band with the nucleus pressed against the vacuole. The result of the dramatic growth of the acidophils and their vacuoles is that the original epidermis is disorganized and compressed against the cuticle. The overall impression obtained by comparing only preparations of newly ecdysed males and fully mature males is that the original epidermal cells have become thickened and vacuolated[2,4]. In certain regions of the integument (for example, pleural folds) the acidophils do not appear, and the original epidermis remains as a well defined layer. It is interesting that Loher[2] observed two types of nuclei in the epidermis of mature males of *S. gregaria*: perhaps this can be explained in terms of the two cell types I have described.

In *S. cancellata* there are scent glands in the abdominal tergites of the mature male: these comprise a glandular cell and a duct cell, in addition to the normal epidermal cells[5]. It seems unlikely that the structures found in *S. gregaria* correspond to those in *S. cancellata*, while the integument of *S. paranensis*[6] seems to be identical with that of *S. gregaria*. Further work is being carried out on the integument of the male desert locust to clarify the site of origin of the acidophilic cells, and the mechanism by which the pheromone is released.

Characteristics of Spontaneous Activity in Tsetse Flies

THE word "spontaneous" is often applied to the activity of tsetse in the field without it being certain that such activity is not environmentally stimulated. During a laboratory study of circadian rhythms in adult tsetse, however, it has now been possible to confirm that flies do move in the near environmental vacuum of constant temperature, humidity, darkness, noise and, probably, smell.

Five characteristics of such apparently spontaneous activity have emerged: (1) an underlying, endogenous, circadian rhythm exists which is clearly demonstrable in constant darkness, but which is obscured in constant light; (2) the amount of activity increases roughly exponentially during the course of starvation (compare refs. 1 and 2); (3) there are very long intervals when no detectable movement occurs; (4) when activity does occur it is performed intensely for brief periods of less than about a minute; (5) the intervals between these bursts may be very regular. This communication draws attention to the last three points; the first two will be reported in detail elsewhere.

Tsetse (*Glossina morsitans orientalis* Vanderplank) were obtained as pupae from the Tsetse Research Laboratory, Langford, Bristol, and reared at $25 \pm 1°$ C and 60 ± 5 per cent relative humidity in a 12 h light : 12 h dark cycle. In these conditions unfed (teneral) flies live about 3–5 days, and fed (post-teneral) flies about a week after their last blood meal.

Activity was measured in rocking-box actographs ($180 \times 85 \times 43$ mm) coupled to a multi-channel event recorder. With a chart speed of 152 mm/h and a trace width of about 0·25 mm, the smallest interval that could be discerned between bouts of activity was about 3 s, and activity of about 20 movements/min could not be distinguished from more intense activity. Tsetse were active in this system exclusively in short bursts separated by long intervals. A burst of activity was usually effectively continuous, but often included very brief breaks, such breaks generally being at least ten-fold shorter than the interval to the next burst.

Table 1. EXAMPLES OF THE FORM OF SPONTANEOUS ACTIVITY IN TSETSE EARLY AND LATE DURING STARVATION

Type of fly and light regime	Mean interval between bursts of activity (min)		Mean length of bursts of activity (s)	
	Early	Late	Early	Late
♂ teneral (DD)	214	45	15	9
♂ teneral (DD)	79	16	28	24
♀ teneral (DD)	39	16	10	10
♀ post-teneral (DD)	147	38	15	22
♀ post-teneral (LL)	64	13	42	34
♀ post-teneral (LL)	100	78	29	27

Early refers to records taken on the first 1–2 days of starvation; late refers to records taken 2–4 days later. Teneral = unfed; post-teneral = fed; DD, constant darkness; LL, constant light; LD, alternating 12 h light: 12 h dark.

Six typical examples of tsetse activity as it changes during starvation are analysed in Table 1. These examples are selected from ninety-six individual activity records covering a total of some 700 fly-days. Because of the high variance caused by the effects of lights-on and lights-off in a light : dark cycle, data have been computed from records taken in constant light or constant darkness only. Further, in order to allow for the variance caused by circadian changes in activity, all means are calculated from entire 24 h periods. The individual differences between the intervals early and late in starvation are highly significantly different (Mann–Whitney U test, $P < 0{\cdot}01$). The distribution of the lengths of the activity bursts for

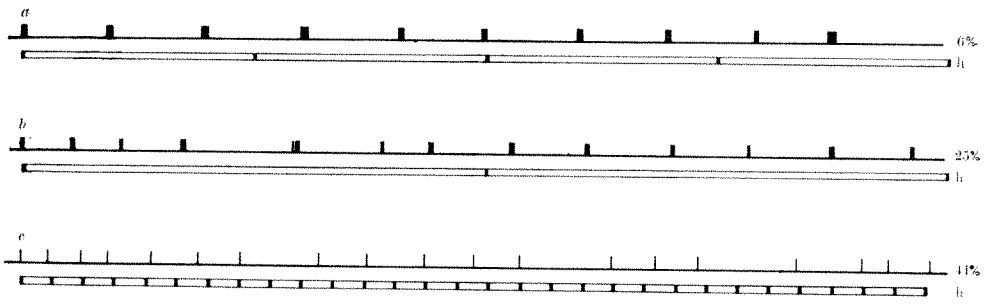

Fig. 1. Records of tsetse activity showing marked periodicity in the bursts of activity. Upper line in each pair is tracing of activity record, lower line is time scale in h. *a* and *b*, Unfed males (DD); *c*, fed female (LL).

each fly is extremely skew, with the lowest class always the largest; confidence limits for the means are therefore not quoted, but in every case the ranges overlap almost completely. The absolute maximum burst lengths observed for these flies were 30, 95, 30, 70, 70 and 54 s, respectively. Changes in the intensity of activity evidently occur primarily by shortening the interval between the bursts of activity; the length of the bursts themselves remains relatively constant. Blow-flies apparently change their activity in an analogous manner[2].

Although considerable variation in the length and form of the activity bursts occurred between individual flies, the general principle of discrete packets of activity separated by much larger intervals was universal. This sporadic nature of tsetse activity in the laboratory confirms inferences from the field[3,4]. In the laboratory, the bursts are performed in a more or less periodic manner at any given time. For example, the standard deviation of the mean intervals taken over any 24 h of record was usually around 75 per cent of the mean. Over shorter periods, much clearer, visually striking periodicities occurred; examples are shown in Table 2 and Fig. 1.

Table 2. EXAMPLES OF PERIODICITY IN THE SPONTANEOUS ACTIVITY OF TSETSE

Type of fly and light regime	No. of intervals	Mean interval (min)	Coefficient of variation (per cent)
♀ post-teneral (DD)	9	147	48
♀ post-teneral (LL)	27	100	41*
♀ post-teneral (LL)	24	10	25
♂ teneral (DD)	12	9	25*
♂ teneral (LD)	14	15	19
♂ teneral (DD)	8	22	15
♂ teneral (DD)	11	18	9
♂ teneral (DD)	8	22	6*

$$\text{Coefficient of variation} = \frac{\text{s.d.} \times 100}{\text{mean}}$$

* Records shown in Fig. 1; other abbreviations as for Table 1.

The duration of the activity bursts, whose maximum length appears to be of the order of 1–2 min, is strikingly similar to the known course of amino-acid consumption during enforced flight. Proline, which seems to serve as an immediate source of rapidly mobilizable energy reserve for flight, is depleted from its maximum resting level to its minimum by 2 min of such treatment[5]. Furthermore, about 30 min to 2 h of rest are required for the complete recovery of the proline concentration; this period is close to the observed duration of the intervals between activity bursts.

These similarities, and the sort of periodicity shown in Fig. 1, are suggestive of rather simple physiological mechanisms controlling spontaneous flight. At least two complications arise, however. First, a lack of any apparent correlation between interval length and burst length does not suggest a simple relationship of the sort found between glycogen and flight duration in *Drosophila*[6]. Second, whereas proline reserves increase for the first 3 days after a blood meal and then decrease rapidly until death[5], no sort of parallel to this is detectable in the activity pattern. Such considerations imply that a simple, mechanistic interpretation may be premature.

I thank Professor J. S. Kennedy for helpful discussion and for reading the manuscript. This work was financed by the Ministry of Overseas Development.

Nitrification and Induction of Nitrate Reductase in Nitrogen-deficient Algae

IT has been known for a long time that nitrogen-deficient algae can reduce added nitrate very rapidly[1,2]. In accordance with this observation, Morris and Syrett[3,4] were able to demonstrate, in *Chlorella* grown in ammonium, the formation of nitrate reductase after the nitrogen source had been exhausted. This seems to contradict the well established fact that nitrate reductase in algae and all other plants studied is an adaptive enzyme which is formed only in the presence of its substrate[5].

While working on the metabolism and enzymes of nitrogen-deficient algae we have been able to confirm the findings of Morris and Syrett[3,4] and to show that when nitrogen is deficient cellular nitrogen compounds are oxidized to nitrate and nitrite, which, in turn, induce the synthesis of nitrate reductase.

Ankistrodesmus braunii (Naegeli) Collins (strain 202–7c from Pringsheim's culture collection at Göttingen), *Chlorella fusca* Shihira et Krauss (=*pyrenoidosa*, strain 211–11m), and *Chlorella vulgaris* Beijerinck (strain 211–8m) were grown in the conditions described by Czygan and myself[6], but with 8×10^{-3} M NH_4Cl and 8×10^{-3} M KCl instead of KNO_3 and NaCl. To measure nitrate reductase activity in cell free extracts, the cells were broken[7] and centrifuged for 10 min at 10,000*g* and 4° C. Our test system contained 1 ml. of the supernatant, 51·0 μmoles KNO_3, 0·5 μmole FAD, 3·75 μmoles sodium dithionite, and 0·05 M phosphate buffer, *p*H 7·5, to make a final volume of 3·0 ml. The concentration of nitrite was determined after 30 min at 25° C.

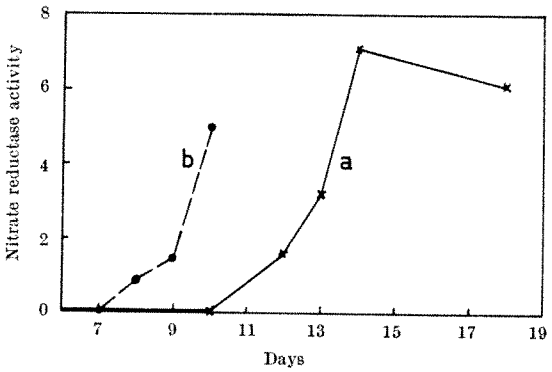

Fig. 1. Nitrate reductase activity in extracts of *Ankistrodesmus braunii*. The figure shows nitrogen depleted (*a*) after 10 days of growth in nutrient solution containing NH_4Cl, or (*b*) by transferring the algae into nitrogen free medium after 7 days of growth. Light intensity was 4,000 lux. Nitrate reductase activity is given in 10^{-3} μmoles of nitrite formed/mg soluble protein/min.

Fig. 1 shows the formation in *Ankistrodesmus braunii* of nitrate reductase after depletion of the ammonium nitrogen in the nutrient solution, and when the algae were transferred to a nitrogen free medium. At the same time, nitrate and nitrite can be detected in the cells (Table 1). It should be stressed that we have never observed any formation of oxidized nitrogen compounds, nor any nitrate reductase activity, in the presence of ammonium ions in the nutrient medium. Thus we assume that this activity is due to an oxidation of cellular

Table 1. FORMATION OF NITRATE AND NITRITE BY NITROGEN-DEFICIENT *Ankistrodesmus braunii*

organic nitrogen compounds which takes place only when nitrogen is deficient in the light, or in the dark in the presence of glucose. We found similar reactions in *Chlorella fusca* and *Chlorella vulgaris*.

The oxidation in algae of cellular nitrogen compounds to nitrate and nitrite is in agreement with observations made with microorganisms and higher plants. Thus heterotrophic nitrification without chemosynthetic carbon dioxide fixation has been found in certain bacteria and fungi[8]. An oxidation of hydroxylamine has been demonstrated in chloroplasts[9] and extracts from higher plants[10]. Yamafuji and Osajima[11] isolated from algae dehydrogenases for ammonia, hydroxylamine, hyponitrite and nitrite. The significance *in vivo* of these enzymes and the occurrence in green plants of reactions leading to the oxidation of organic and inorganic nitrogen compounds, however, have so far remained doubtful, in spite of occasional reports on the formation in the light of nitrate in higher plants grown in the absence of nitrate[12].

Copper Tolerance in the Marine Fouling Alga *Ectocarpus siliculosus*

INTRASPECIFIC variation in marine algae in response to habitat conditions has been proposed[1] and, in some cases[2,3], demonstrated. During an investigation into the ship-fouling properties of the brown alga *Ectocarpus siliculosus* (Dillw.) Lyngb. we have found evidence of differential response to dissolved copper which may be associated with the habitats from which the populations were taken.

The populations studied were located at Rhosneigr, Anglesey, an open uncontaminated rocky shore, and from the hulls of two ocean-going freighters treated with copper-based antifouling preparations. Unialgal cultures were established from excised pieces of filament taken from ten plants in each population. The material was grown together in a modified enriched seawater medium[4]. No soil extract or chelating agents were incorporated.

Known volumes of plant material (0·05–0·07 ml.) were measured by means of slow centrifugation (4,000 r.p.m.) for 10 min in 'Wintrobe' blood sedimentation tubes[5] and used as inoculum in successive media containing different concentrations of dissolved copper (as $CuCl_2$). The cultures, all 100 ml., were grown at 10°–15° C under continuous fluorescent 'White' light of 2,700 lux for 5 weeks. Volume assessments of total plant material were made weekly and the percentage increase or decrease in volume was noted; the plant material was always centrifuged in the appropriate medium. Each experiment was run in duplicate.

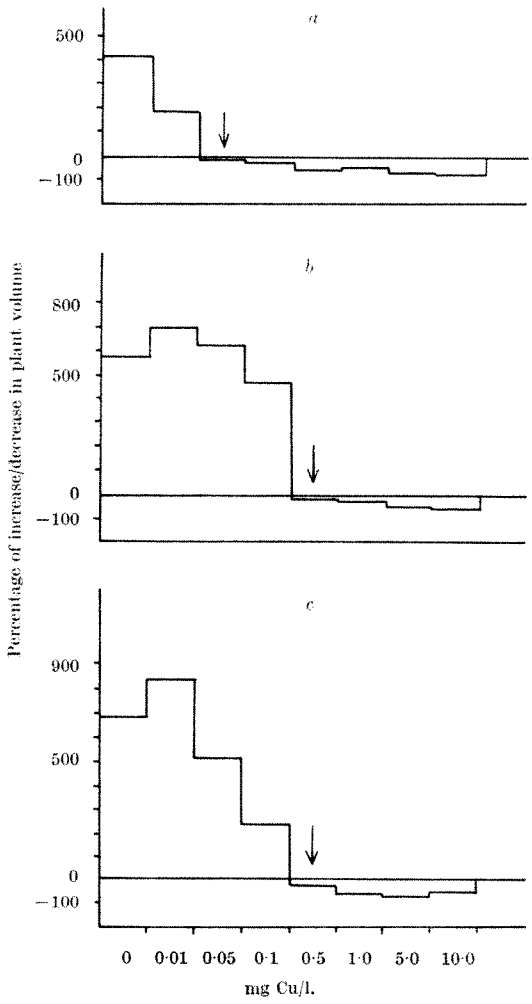

Fig. 1. Response to dissolved copper after 35 days in culture by populations of *Ectocarpus siliculosus* from (*a*) Rhosneigr, Anglesey, and (*b*) and (*c*) the hulls of two ocean-going freighters. Arrows indicate critical toxicant concentration for each population.

Results showed close agreement and the mean values in Fig. 1 indicate that the ship-borne populations of *E. siliculosus* are more tolerant to dissolved copper than the Rhosneigr population by a factor of 10.

This bioassay method proved satisfactory and the concentration of toxicant at which there is no increase or decrease in plant volume (critical toxicant concentration) seems to be more useful in practice than a subjective estimate of plant vigour.

The different responses to copper by shore and ship-borne populations of *Ectocarpus* are in evident agreement with well established cases of heavy metal tolerance in higher plants[6] and fungi[7]. Copper has long been used as a base for antifouling preparations and the faster growth of plants of both ship-borne populations in low copper concentrations than in control conditions suggests that they were tolerant to the metal.

It is interesting that *E. siliculosus* and *Enteromorpha* spp., the most frequently encountered ship-fouling plant taxa, are polymorphic, euryhaline, pollution-tolerant and cosmopolitan in distribution. But the characteristics which enable these species to exploit a wide range of habitats and environmental conditions seem likely to be based at least as much on a high intrinsic genetic variability as on a general physiological toughness.

The adaptive aspects of these findings are likely to be important in several marine ecological problems, for they disclose a situation analogous to DDT resistance in insects. This work also goes some way towards explaining the

incomplete success of antifouling preparations and the difficulty of developing an infallible product. The economic implications to the shipping industry and to antifouling research in the era of the super-tanker are self-evident.

We thank Professor A. D. Bradshaw for his help.

Basic Rectangle of the Mandible

The arrangement of teeth in the lower jaw of man (Hominidae) may be distinguished from that of apes (Pongidae) by means of the "basic rectangle of the mandible"[1]. Leakey defined the rectangle and suggested that, in the Pongidae, the sides "are nearly twice as long as the upper and lower ends"; whereas in the Hominidae "the basic rectangle is seen to be nearly a square"[1]. Leakey presented several illustrative diagrams but he did not otherwise quantify his measurements.

The basic rectangle may be treated more precisely by computing an index derived from measurements of the sides of the rectangle. When the antero-posterior length of the rectangle times 100 is divided by its breadth, an index results which I call the index of the basic rectangle of the mandible (BRM Index). I measure the length of the rectangle as the shortest distance between the anterior alveolar margin of the left central incisor and a straight edge placed in contact with the posterior surfaces of the third molar teeth. The breadth is the distance between the points of contact of the two third molars with the straight edge.

In order that mandibular shape may be compared among higher primates, and that comparisons among fossil primates may be more meaningful, I now present data on the BRM Index for nineteen genera of living primates including *Homo sapiens* (Table 1). (Representative rectangles are shown in Fig. 2.) Measurements of length and breadth of the rectangle were taken on mandibles of known sex of adult *Pan troglodytes*, *Gorilla gorilla gorilla*, *Pongo pygmaeus pygmaeus*, *Hylobates concolor*, *Cercopithecus nictitans*, *C. aethiops*, *Nasalis larvatus*, *Colobus badius*, *Macaca radiata*, *M. nemestrina*, *M. fascicularis*, *M. mulatta*, *M. arctoides*, *Papio* sp., *Callimico goeldii*, *Saimiri sciureus*, *Callicebus moloch*, *Aotus trivirgatus*, *Ateles fusciceps*, *Pithecia pithecia*, *Cacajao rubicundus*, *Alouatta seniculus*, and *Tarsius syrichta*. The classification is that of Napier[2]. The mean index and its standard error were computed separately for males and females of each species. When male and female indices did not differ ($P > 0{\cdot}05$), the sexes were combined. There was no significant difference among the five macaque species for either sex, so all female macaques were combined and all male macaques were combined. The measurements for *Homo sapiens* in Table 1 were taken on mandibles of known age and sex from American Negroes, aged 19 to 60 years.

As Leakey has suggested[1], mandibular shape in living man differs clearly from that in living pongids as indicated by the BRM Index. Table 1 shows that the index in some Cebidae and the tarsier, however, overlaps the index for *Homo sapiens*. All the coefficients of variation are less than 10, suggesting that none of the samples represents a mixed population; the low coefficient of variation in some genera may represent inadequate sampling.

Human mandibles were considered with respect to age and race. Adult Negro mandibles did not differ with age. (The coefficient of correlation for the BRM Index with age,

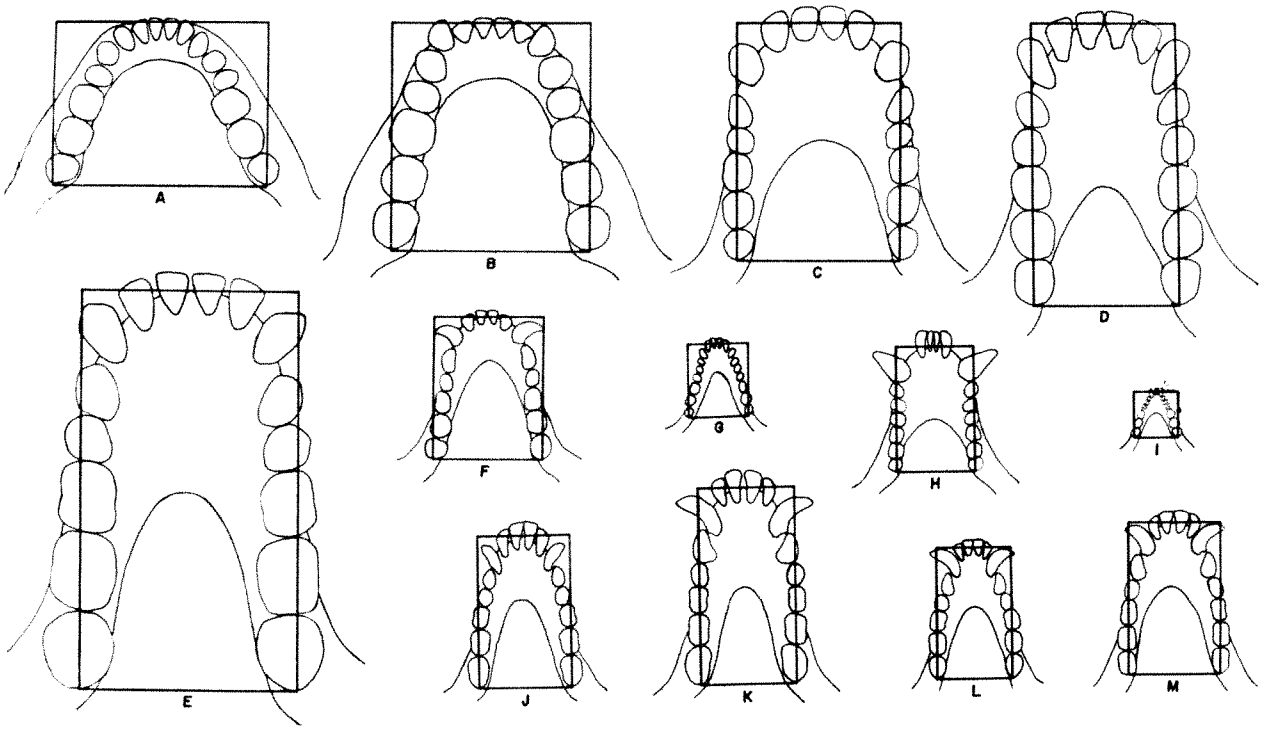

Fig. 1. The basic rectangle of the mandible in representative genera of living primates (all to the same scale). The BRM Index for each is given in parentheses. *A*, *Homo sapiens*, white (77); *B*, *Homo sapiens*, negro (116); *C*, *Pan*, (145); *D*, *Pongo* (196); *E*, *Gorilla* (185); *F*, *Hylobates* (133); *G*, *Callicebus* (120); *H*, *Cacajao* (160); *I*, *Tarsius* (104); *J*, *Macaca radiata*, female (166); *K*, *Macaca mulatta*, male (205); *L*, *Cercopithecus aethiops*, male (175); *M*, *Cercopithecus nictitans*, male (168).

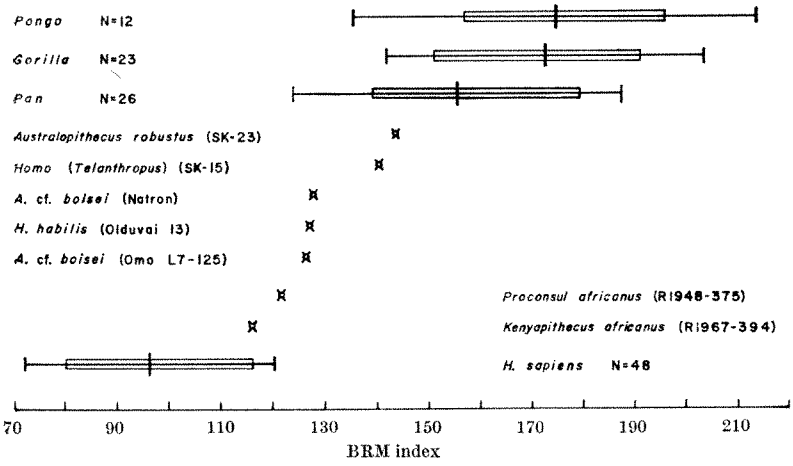

Fig. 2. The index of the basic rectangle of the mandible (BRM Index) in living and fossil hominids and pongids. The total length of each figure indicates the estimated population range using limits of three times the standard deviation on either side of the mean; the enclosed space represents the observed range of variation; and the cross line marks the mean; N is the sample size in each case.

$r = -0{\cdot}12 \pm 0{\cdot}16$.) There was, however, a striking racial difference. A sample of twelve American White mandibles had an average BRM Index of $86{\cdot}7 \pm 2{\cdot}2$, much lower than that for American Negro reported in Table 1 ($P < 0{\cdot}0001$). Racial differences are illustrated in Fig. 1*A* and *B*. It should be noted that while the Negro dental arch has been referred to as U-shaped[3], even in the extreme case illustrated in Fig. 1*B*, the rows of molar teeth are not parallel.

V	9·2	3·6	7·9	5·0	5·9	6·5	3·0	9·9	4·7	4·9
M–F	nonsig.		nonsig.		nonsig.		nonsig.		nonsig.	

N = sample size; $\bar{x}$ = mean; s.e. = standard error of the mean; *V* = coefficient of variation; M–F = significance of difference between male and female means: nonsig., $P \gtrsim 10$ per cent; *, $P < 2{\cdot}5$ per cent; †, $P < 1$ per cent; ‡, $P < 0{\cdot}1$ per cent. All measurements are in mm.

Sex differences in the human mandible are well known[4,5]. As expected, the length and breadth of the basic rectangle are greater in the human male than in the female, but sexual dimorphism is lacking in the shape of the arch as expressed by the BRM Index (Table 2). The index of all the apes also lacks significant sexual dimorphism, as do the length and breadth measurements of the chimpanzee (*Pan*) and the gibbon (*Hylobates*). Differences in index between male and female occur, however, in some platyrrhine and catarrhine monkeys.

Estimates for population ranges of the BRM Index of living hominids and pongids, using limits of three times the standard deviation on either side of the mean, are shown in Fig. 2. Estimated values are also presented for several fossil hominids and pongids, based on casts and photographs. The dental arch of australopithecines is less "parabolic" than that of *Homo erectus* or *Homo sapiens*; thus indices for some australopithecines fall within the estimated population range for living pongids. The indices for both *Kenyapithecus africanus* and *Dryopithecus* (*Proconsul*) *africanus* fall almost within the estimated population range for American Negro. While post-mortem distortion may have altered the shape of the dental arch in some fossil mandibles, the similarity in the BRM Index of the two Rusinga Island mandibles in Fig. 2 supports the suggestion[6], arrived at on the basis of other evidence, that mandible No. 394 is most similar in its overall morphology to *Dryopithecus* (*Proconsul*) *africanus*. If "*Kenyapithecus*" *africanus* is linked "clearly with the family Hominidae"[1] on the basis of shape of the basic rectangle, then *Proconsul africanus* must be also, although most would agree the latter is not. Whether the shape of the dental arch is expressed as the basic rectangle, the anterior mandibular index[7], or the degree of posterior divergence[8], it is clear that in Miocene hominoids the shape was quite different from that in living apes, and in many early hominids the shape was different from that in living man. The functional and taxonomic significance of these differences has not yet been explained adequately.

I conclude that, whereas the basic rectangle of the mandible may be useful taxonomically among living primates, it does not serve to distinguish between pongids and hominids when fossil hominoids are considered. The shape of the basic rectangle, therefore, does not provide evidence for placing *Kenyapithecus africanus* within the Hominidae.

I thank Dr J. L. Angel and Dr R. Thorington (US National Museum), Dr J. C. Moore (Field Museum of Natural History, Chicago), Dr R. G. Van Gelder and Dr Sydney Anderson (American Museum of Natural History), and Dr S. L. Washburn (University of California, Berkeley) for permission to study material in their collections. I also thank Mr R. L. Susman for technical assistance. This work was supported in part by a University of California research grant.

Book Reviews

ROCKET RECORDS

The Papers of Robert H. Goddard

Including the Reports to the Smithsonian Institution and the Daniel and Florence Guggenheim Foundation, Vols. 1–3. Edited by Esther C. Goddard in association with G. Edward Pendray. Vol. 1: 1898–1924. Pp. xx+1–560. Vol. 2: 1925–1937. Pp. x+561–1104. Vol. 3: 1938–1945. Pp. x+1105–1707. (McGraw-Hill: New York and London, 1970.) 1,440*s*; $150.

"THE dream of yesterday is the hope of today and the reality of tomorrow," wrote Robert H. Goddard in 1904 at the age of 21; and for the next forty years he strove to bring the liquid-fuel rocket from dream to reality. At his death in 1945, Goddard left more than 6,000 pages of orderly and continuous records, of which a generous selection—chiefly correspondence, technical reports and entries from Goddard's daily diary—appears in these volumes, chronologically arranged and well printed. Mrs Esther Goddard and her co-editor, Dr Pendray, are to be warmly congratulated on what is not only a worthy monument to the life work of her late husband, but also a fascinating record of an inventor's career for anybody interested either in rocketry or in the history of technology.

Robert H. Goddard was born at Worcester, Massachusetts, in October 1882. His parents moved to Boston soon afterwards, but in 1898 they returned to Worcester, where Goddard remained for much of his life. His family was quite prosperous, and he was allowed to indulge in some boyish inventions, such as trying to fly hydrogen balloons made of thin aluminium sheet and firing special arrows 300 feet into the air. He was away from school because of illness between 1899 and 1901, and did not gain his first degree until he was 25; this was followed by a doctorate at Clark University in 1911. After research in physics, and a serious attack of tuberculosis, Goddard was appointed assistant professor in physics at Clark University in 1915 and full professor in 1920. He retained this appointment until 1943, although on leave of absence from 1934.

Goddard's first patent for a liquid-fuel rocket was issued in July 1914, and a month later he completed a theoretical paper on the problem of reaching great altitudes by rocket. He calculated that, with perfect efficiency and an initial acceleration of about $3g$, an initial mass of about 1,000 pounds would be enough to send a mass of 1 pound to the surface of the Moon. In September 1916 Goddard asked the Smithsonian Institution for a grant towards practical work on liquid rockets: the answer was "yes", largely on the recommendation of Dr C. G. Abbot, then director of the Smithsonian Astrophysical Observatory. The Smithsonian Institution continued to finance Goddard until 1930, when he began receiving grants from the Guggenheim Foundation which continued to the end of his life. It was in March 1926, nine years after the Smithsonian grants began, that Goddard succeeded in launching the first liquid-propellant rocket, at Auburn, Massachusetts. The rocket, which weighed 5 kg at launch, was powered by gasoline and liquid oxygen, and flew to a height of 12 m and a distance of 55 m. Goddard built steadily on this small beginning, continually improving the design of combustion chambers, nozzles, propellant flow systems and methods of stability and control. In 1932 came the first flight with control by gyroscopic stabilization and vanes in the exhaust jet, and in 1935 the first supersonic flight. Subsequently he worked on turbopumps for propellant delivery, variable-thrust motors and nozzle-cooling techniques. Goddard did not develop very large rockets, because he was primarily concerned with upper-atmosphere sounding rockets rather than weapons; but nearly every feature of the German V2 was covered by his patents and first used in his rockets.

For forty years Goddard worked alone, apart from a few assistants, in face of scepticism from the public and most scientists, uncertainty about next year's finance, and repeated failures of the rockets. But he never wavered in perseverance or enthusiasm, and the laconic diary entries scarcely vary as the years roll by: "1916 June 24: Tried to fire short nozzle in small tank in morning. . . . 1944 Aug. 25: Tried starts morning and afternoon". What inner drive kept him going so steadily, free from doubt or despondency? Goddard does give one clue to help us in answering this unanswerable question. His thoughts first turned towards rockets and space in 1898 after reading H. G. Wells's *War of the Worlds*, with its story of Martian invaders and its "wonderfully true psychology"; and the experience that directed his life came in the following year, on October 19, 1899, to be precise, when he climbed a cherry tree at the family home, Maple Hill: "It was one of the quiet, colorful afternoons of sheer beauty which we have in October in New England, and as I looked toward the fields at the east, I imagined how wonderful it would be to make some device which had even the possibility of ascending to Mars, and how it would look on a small scale, if sent up from the meadow at my feet". From then on, October 19 was marked each year in his diary as "Anniversary Day", when he would if possible return to the cherry tree, almost as if he were a knight of old renewing his vows. Shelley's lines,

> I do remember well the hour which burst
> My spirit's sleep: a fresh May-dawn it was . . .

apply to many single-minded and inner-directed artists or inventors, and Goddard is among them, even if his May morning was an October afternoon. But Goddard also conforms to Edison's dictum that genius is 1 per cent inspiration and 99 per cent perspiration, for he was careful and methodical as well as enthusiastic: the fatal explosions that marred so many early experiments with rockets are conspicuous by their absence in his work. On the other hand, his methodical approach did tend to narrow his interests. He lacks the breadth of vision shown by the greatest inventors like James Watt, and, in spite of his insight into the future of space flight, Goddard's writings are a little too plain and workmanlike, and deficient in verve or excitement. Nevertheless Goddard deserves a high place among the single-minded inventors who have concentrated on a single vehicle and have driven it successfully along that hard road from hope to reality.

D. G. KING-HELE

EHRENFEST'S CHARACTER

Paul Ehrenfest

Vol. 1: The Making of a Theoretical Physicist. By Martin J. Klein. Pp. xvi+330. (North-Holland: Amsterdam and London, 1970.) 70*s*; $8.40.

THIS first volume of the biography of Paul Ehrenfest takes the reader from the date of his birth in Vienna in 1880 to just beyond the end of the First World War in 1920.

This time span includes the heroic period of the quantum theory and the atomic models with Planck, Einstein, Bohr, Sommerfeld, Lorentz, Boltzmann and others as the principal figures in theoretical physics. Paul Ehrenfest differed from these men because he had never acquired the skill to carry through any extensive calculation and emotionally he was possibly not suited to do so. His strength was directed towards critical analysis, asking the pertinent question, clearing up obscurities, getting to the bottom of a problem. This was often done with the aid of the "Socratic dialogue", verbal or in letters, with many of the outstanding theoreticians of the time. There is nothing novel in this as a method of research in theoretical physics, but the intensity and determination which Ehrenfest applied and the enthusiasm he was able to stimulate in his participants were unusual. This side of Ehrenfest's character was also the reason that he became famous as an inspiring teacher and lecturer. An impressive example can be found in his biographer's account of the inaugural lecture given by Ehrenfest when appointed professor at the University of Leyden in 1912.

A third of this volume is devoted to Paul Ehrenfest's personal biography: his youth in Vienna, the years of study at its university where L. Boltzmann's influence first directed him to statistical mechanics, the highly important stay of eighteen months in Göttingen and the five years' period in Russia. During these "Wanderjahre", Ehrenfest became acquainted with the European physicists of eminence and their problems. Being married to a Russian mathematician and the father of two girls, it became urgent for him to find an academic position with a steady income. After a disappointing search, help came from an unexpected side: Lorentz chose him as his successor.

It is characteristic of Ehrenfest's seriousness of mind and of his self discipline that he kept extensive notes not only on personal matters but of discussions, scientific questions and ideas occurring to him so as to make sure to reflect further on them at a later date. These notebooks and diaries provided his biographer with a mine of information, permitting him to create a true image of Paul Ehrenfest (pp. 90–91, a programme for little Tatyana's future intellectual development, is most typical).

The principal section of the volume is concerned with the history of atomic physics and the contribution Ehrenfest has made to it. There are the following chapters arranged chronologically: the critic of statistical mechanics, theoretical miscellany, the essential nature of the quantum hypothesis and the adiabatic principle.

The volume finishes with a chapter "Einstein und Ehrenfest". It gives the volume a charming ending full of glimpses into the bonds between the two friends and shows the human side of the awe-inspiring phenomenon of Einstein.

On reading this book, one cannot help admiring the erudition of the author, the agreeable style of his language and his ability to present physics in clear terms with didactic skill. This volume can be warmly recommended and I am looking forward to the second volume.

E. Bretscher

COSMIC RADIATION

Proceedings of the Eleventh International Conference on Cosmic Rays

Budapest, August 25–September 4, 1969. Vol. 1: Origin and Galactic Phenomena. Edited by A. Somogyi. (*Acta Physica* Supplement, Vol. 29.) Pp. 571. (Akadémiai Kiadó: Budapest, 1970.) 220*s*.

If in no other way, this book is remarkable both for the speed with which it has been produced (it is only a year since the conference which it reports took place) and for the high quality of its appearance, which does not seem to have suffered at all from the speed of its preparation. These factors must owe much to the production of the volume as a supplement to a journal (*Acta Physica*) where both the editors and publishers are familiar with producing the printed word from manuscripts quickly and accurately—perhaps there is a lesson here for those contemplating the publication of other conference reports.

This volume is the first of four to be published covering the Proceedings of the Eleventh Conference on Cosmic Rays, and is restricted to those papers dealing with the origin of cosmic radiation and galactic phenomena. The full texts of all the relevant original contributions are included, and although in several cases these contributions deal with work which has also been reported elsewhere, this completeness has resulted in a most valuable review book and source from which other relevant papers can be found. It is impossible to do justice to a book of this kind in a limited review; all that can be said is that this volume comprehensively covers the field which it is reporting, and if the other three volumes cover their fields in a similar detailed manner, then the set will become an essential and much used part of every astrophysics library. Although the price of these volumes will probably be far too high for the individual astronomer to buy them, they are good value when compared with the cost of similar volumes produced by some other publishers, and this sort of comprehensive review is in any case much more suited to the libraries of academic institutions than to the individual's private collection.

John Gribbin

PROBLEMS OF EPISTEMOLOGY

Studies in History and Philosophy of Science

Edited by Gerd Buchdahl and L. L. Laudan. Vol. 1, Nos. 1 and 2. Quarterly. (Macmillan (Journals): London, May and August 1970.) 100*s* per annum; 30*s* per issue.

This new quarterly, according to the editors' manifesto, intends to promote studies leading to "an understanding of the scientific enterprise", which (as they rightly emphasize) demands an approach that "must be simultaneously historical and philosophical". They are sorry for the "gap that has grown between the two disciplines" of history and philosophy of science, and which they somehow hope to bridge by providing a meeting place for philosophically minded historians and historically minded philosophers.

In entertaining such optimistic expectations, they do not seem to realize that the place of philosophical thinking in science has undergone a radical change since the beginning of the nineteenth century. In the preceding period of formation of modern science, philosophical reflexion was—for good reasons—an inherent part of the scientific activity of the great pioneers; by the end of this period, when science had acquired its own method and put it on a solid foundation, and at the same time, under the pressure of accumulated experience and increasing refinement of the techniques of investigation, had divided into a number of specialized disciplines, makers of philosophical systems—again for obvious reasons—were left irrevocably behind. What scientists still need is a continued analysis of the basic assumptions underlying their activity, but this epistemological analysis requires such an intimate knowledge of the most technical aspects of scientific investigation that it can only be carried out usefully by the scientists themselves. This situation has not, of course, prevented people from talking glibly about the foundations and the meaning of science without taking the precaution of acquiring the necessary experience; but their self-styled description as philosophers of science should not deceive any but themselves about the true status of their verbal exercises.

History of science, on the other hand, has a vital part to play in epistemological research: for no understanding of the sources of human knowledge can be complete without a reliable record of the actual evolution of scientific ideas. It has also to struggle with methodical difficulties; but it is successfully shedding the infantile impediments of chauvinism, hero worship, silly anecdote-mongering, and reaching the mature sophistication that will allow it to fulfil its task responsibly. To associate it, at this critical stage, with the worst dilettantism of our time is—the purest of intentions notwithstanding—to disserve rather than to help it. Indeed, to illustrate my point I have only to take the first number of this journal. It consists of two long essays: the first, by J. E. McGuire, on "Atoms and the Analogy of Nature", is an able, well documented and well argued, historical study of a significant problem of epistemology debated in Newton's time—history of science at its best; the other, entitled "In Defence of Classical Physics", is another of Professor P. K. Feyerabend's extravaganza—philosophy of science, so called, at its worst: bombastic, pointless chatter about dimly perceived issues long since settled by the physicists, and completely out of touch with the serious problems they are actually facing. If this first number is representative of the editors' policy, one must fear that one half of the journal will just be dead weight needlessly appended to its valuable historical content.

Fortunately, the second issue goes some way to temper such apprehensions: its contents—including papers of great interest and substantial essay reviews—are entirely of historical character and of high standard. Let us hope, therefore, that the historians will keep the philosophers under control, and all will be well. L. ROSENFELD

VARIABLE STARS

The Dwarf Novae

By John S. Glasby. Pp. 293. (Constable: London, August 1970.) 60*s*.

MR GLASBY is director of the Variable Star Section of the British Astronomical Association; he is an able and indefatigable observer of variable stars in general and of dwarf novae in particular. His new book is an exhaustive review of what is known, or has been thought, about the dwarf novae, and contains extensive bibliographies; it consists, in approximately equal proportions, of a synthesis of published papers and a description of the individual stars.

In the descriptive section, the author is on his own ground—indeed, many of the illustrative light curves are drawn from his own observations. But he is less at home in reviewing the observational and interpretative attempts of professional astronomers. There are about half a dozen important mistakes: for instance, evolving stars are said to have begun hydrogen burning in their centres (p. 84), and doppler shifts are not expected unless the motion is directly in the line of sight (pp. 85, 234). The author also forgets for whom he is writing: thus, he explains stellar magnitudes at the outset, but later writes gaily about the Hertzsprung–Russell (or Russell–Hertzsprung, as he insists on calling it) diagram, break-off points, zero-age main sequences, Kelvin time-scales, and Markov chains, all without previous explanation. There are also several careless mistakes. Not only is there a considerable number of inconsistencies in the text, and discrepancies between the text and several of the diagrams, but the values quoted on different pages for such quantities as orbital periods, spectral types and radial velocities sometimes conflict. The Crossley reflector, already credited with an aperture of 80 inches on page 213, grows still further by page 243.

In view of the occurrence of short-period light variations in at least some of the dwarf novae, it is a little surprising that Glasby makes no reference to any visual observations of such changes; and none of the visual light curves indicates any—not even that of U Gem, a system showing conspicuous eclipses when at minimum light. Furthermore, the number of observations used in plotting the magnitude variations seems, in many cases, to have been scarcely greater than the number of inflexions drawn in the light curves: it would have been better if Glasby had plotted the actual observations rather than just the curves.

In spite of careless grammatical mistakes and poor punctuation, the volume makes a substantial, if indigestible, meal for those interested in dwarf novae; it can be recommended as an introductory review, and will be of special interest to the amateur observers upon whose work our knowledge of the dwarf novae so largely depends.

ROGER GRIFFIN

SILICATE WEATHERING

Chemical Weathering of the Silicate Minerals

By F. C. Loughnan. Pp. x + 154. (Elsevier: New York and Barking, Essex, 1969.) 100*s*.

LOUGHNAN has written a book that will be welcomed by students of geology, geochemistry, soil sciences and various other related disciplines. There is really no other book like it in the field of chemical weathering of silicates, and in the present period of public concern about ecology, this volume ought to provide the needed quantitative information about the mechanisms of weathering of rocks and the formation of soil. In many ways, the present volume is comparable with W. D. Keller's *The Principles of Chemical Weathering* (1957), but although Keller's work had the same central theme, it was more a collection of lecture notes than a proper textbook. Loughnan has indeed written a cohesive textbook, perhaps more suitable for research students than for final year undergraduates.

The book has six chapters. The second chapter, on the structures and properties of the primary and secondary minerals, includes some basic, but selective, crystallographic information which will be appreciated by students and teachers alike. The third chapter, on the chemistry of weathering, very successfully proves that the basic laws of chemical equilibria can indeed explain the observed chemical weathering phenomena. The fifth and sixth chapters abound with many examples, quite a few from Loughnan's own well-known work in this field.

The references are well selected, but most are pre-1966. In the age of sea floor spreading, it is a pity that chemical weathering under specifically oceanic conditions is not discussed. SUBIR BANERJEE

BASIC PALAEOMAGNETISM

History of the Earth's Magnetic Field

By David W. Strangway. (Earth and Planetary Science Series.) Pp. viii + 168. (McGraw-Hill: New York and Maidenhead, August 1970.) 67*s*.

THERE are many differing views on the precise nature of the principle of uniformitarianism but, philosophy apart, the fact remains that man's success in extending his knowledge of the Earth backward in time for millions of years is one of his most remarkable achievements. From the magnificent intellectual edifice constructed by the great nineteenth-century geologists to the revised vision of the Earth embodied in the new global tectonics, man has steadfastly refused to be bound intellectually by the limitations imposed by his geologically infinitesimal life span.

And of all the properties of the Earth which have been traced through geological time, the most significant and important is undoubtedly the geomagnetic field as recorded in the Earth's rocks, for our whole modern view of the Earth as an internally dynamic body ultimately stems from the establishment of continental drift as a viable hypothesis, largely as a result of palaeomagnetic study. Naturally enough perhaps, the conceptual end results of palaeomagnetism—continental drift itself, sea floor spreading, geomagnetic dynamos, and the like—have attracted more than their fair share of attention from "popular" writers. On the other hand, palaeomagnetism *per se*, the foundation of the modern view, has received almost none.

To redress this imbalance somewhat, Strangway has written this introductory book which covers, in a simplified yet coherent and eminently readable way, all of the topics one would expect to encounter in a book on basic palaeomagnetism and rock magnetism. In reading it I could not help but reflect, somewhat sadly, that North America has a definite edge over Europe when it comes to producing books at this level. It is, I suspect, largely a question of public need. With more than two thousand universities and colleges, a system of higher education which tends to the non-specialist, a high school situation in which one in three seniors studies Earth science, and a noticeably more scientifically literate population, there is a large market for this sort of book in the United States. It will sell proportionately far less in Britain—which is a pity, and certainly no reflexion on its quality nor on the achievement of its author. PETER J. SMITH

STATISTICAL MECHANICS

Elementary Statistical Mechanics

By G. A. P. Wyllie. (Hutchinson University Library.) Pp. vii + 148. (Hutchinson: London, June 1970.) 35*s* boards; 15*s* paper.

THIS book is a simplified version of a lecture course, delivered over several years, by the author at the University of Glasgow. The standpoint of E. T. Jaynes, regarding the quantitative measure of information, is used to establish the canonical distribution as the least informative description of a system whose exact constitution and average energy are prescribed. The book is elementary in the sense that it requires only a knowledge of mathematics at first year university level and an elementary knowledge of quantum mechanics.
